Google

Acerca de este libro

Esta es una copia digital de un libro que, durante generaciones, se ha conservado en las estanterías de una biblioteca, hasta que Google ha decidido escanearlo como parte de un proyecto que pretende que sea posible descubrir en línea libros de todo el mundo.

Ha sobrevivido tantos años como para que los derechos de autor hayan expirado y el libro pase a ser de dominio público. El que un libro sea de dominio público significa que nunca ha estado protegido por derechos de autor, o bien que el período legal de estos derechos ya ha expirado. Es posible que una misma obra sea de dominio público en unos países y, sin embargo, no lo sea en otros. Los libros de dominio público son nuestras puertas hacia el pasado, suponen un patrimonio histórico, cultural y de conocimientos que, a menudo, resulta difícil de descubrir.

Todas las anotaciones, marcas y otras señales en los márgenes que estén presentes en el volumen original aparecerán también en este archivo como testimonio del largo viaje que el libro ha recorrido desde el editor hasta la biblioteca y, finalmente, hasta usted.

Normas de uso

Google se enorgullece de poder colaborar con distintas bibliotecas para digitalizar los materiales de dominio público a fin de hacerlos accesibles a todo el mundo. Los libros de dominio público son patrimonio de todos, nosotros somos sus humildes guardianes. No obstante, se trata de un trabajo caro. Por este motivo, y para poder ofrecer este recurso, hemos tomado medidas para evitar que se produzca un abuso por parte de terceros con fines comerciales, y hemos incluido restricciones técnicas sobre las solicitudes automatizadas.

Asimismo, le pedimos que:

+ *Haga un uso exclusivamente no comercial de estos archivos* Hemos diseñado la Búsqueda de libros de Google para el uso de particulares; como tal, le pedimos que utilice estos archivos con fines personales, y no comerciales.
+ *No envíe solicitudes automatizadas* Por favor, no envíe solicitudes automatizadas de ningún tipo al sistema de Google. Si está llevando a cabo una investigación sobre traducción automática, reconocimiento óptico de caracteres u otros campos para los que resulte útil disfrutar de acceso a una gran cantidad de texto, por favor, envíenos un mensaje. Fomentamos el uso de materiales de dominio público con estos propósitos y seguro que podremos ayudarle.
+ *Conserve la atribución* La filigrana de Google que verá en todos los archivos es fundamental para informar a los usuarios sobre este proyecto y ayudarles a encontrar materiales adicionales en la Búsqueda de libros de Google. Por favor, no la elimine.
+ *Manténgase siempre dentro de la legalidad* Sea cual sea el uso que haga de estos materiales, recuerde que es responsable de asegurarse de que todo lo que hace es legal. No dé por sentado que, por el hecho de que una obra se considere de dominio público para los usuarios de los Estados Unidos, lo será también para los usuarios de otros países. La legislación sobre derechos de autor varía de un país a otro, y no podemos facilitar información sobre si está permitido un uso específico de algún libro. Por favor, no suponga que la aparición de un libro en nuestro programa significa que se puede utilizar de igual manera en todo el mundo. La responsabilidad ante la infracción de los derechos de autor puede ser muy grave.

Acerca de la Búsqueda de libros de Google

El objetivo de Google consiste en organizar información procedente de todo el mundo y hacerla accesible y útil de forma universal. El programa de Búsqueda de libros de Google ayuda a los lectores a descubrir los libros de todo el mundo a la vez que ayuda a autores y editores a llegar a nuevas audiencias. Podrá realizar búsquedas en el texto completo de este libro en la web, en la página `http://books.google.com`

This is a reproduction of a library book that was digitized by Google as part of an ongoing effort to preserve the information in books and make it universally accessible.

COLONEL SIR JOHN SMITH YOUNG, C.V.O.

SECRETARY.

SIR HENRY TRUEMAN WOOD, M.A.

Assistant Secretary—G. K. MENZIES, M.A.
Assistant Secretary for the Indian and Colonial Sections—SAMUEL DIGBY, C.I.E.
Chief Clerk—GEORGE DAVENPORT. *Accountant*—J. H. BUCHANAN. *Auditors*—MESSRS. KNOX, CROPPER & CO.

SESSIONAL ARRANGEMENTS.

The Opening Meeting of the One Hundred and Fifty-Eighth Session was held on Wednesday evening, November 15th, when an address was delivered by LORD SANDERSON, G.C.B., K.C.M.G., Vice-President and Chairman of the Council. (See pp. 6–15, below.)

PAPERS TO BE READ BEFORE CHRISTMAS.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock:—

NOVEMBER 22.—JAMES DOUGLAS, LL.D., Past President of the American Institute of Mining Engineers, "The Industrial Progress of the United States of America." The Right Hon. Sir HENRY MORTIMER DURAND, G.C.M.G., K.C.S.I., K.C.I.E., late H.B.M. Ambassador at Washington, will preside.

,, 29.—A. E. BERRIMAN, "The Efficiency of the Aeroplane."

253260

Hosted by Google

DECEMBER 6.—J. A. J. DE VILLIERS, Hon. Secretary of the Hakluyt Society, "British Guiana and its Founder, Storm van 's Gravesande." LORD REAY, G.C.S.I., G.C.I.E., LL.D., will preside.

" 13.—W. YORATH LEWIS, Mem.Am.Soc.M.E., A.M.Inst.Mech.E., A.M.I.E.E., "Continuous Service in Passenger Transportation."

INDIAN SECTION.

Thursday afternoon, at 4.30 o'clock:—

DECEMBER 14.—J. TRAVERS JENKINS, Ph.D., D.Sc., Superintendent of the Lancashire and Western Sea Fisheries, "Fisheries of Bengal."

PAPERS TO BE READ AFTER CHRISTMAS.

CECIL THOMAS, "Gem Engraving."

F. MARTIN DUNCAN, "The Work of the Marine Biological Association."

H. A. ROBERTS, M.A., "The Relations of Science to Commerce and Industry."

JOHN NISBET, D.Oec., late Conservator of Forests, Burma, "The World's Decreasing Timber Supplies."

FRANK WARNER, "Silk."

CHARLES C. ALLOM, "The Development of Artistic Skill in the Applied Arts."

CYRIL DAVENPORT, "Illuminated MSS."

ERNEST KILBURN SCOTT, A.M.Inst.C.E., M.I.E.E., "The Manufacture of Nitrates from the Atmosphere."

CHARLES BRIGHT, F.R.S.E., M.Inst.C.E., M.I.E.E., "The Administration of Imperial Telegraphs."

HAROLD COX, "The Interdependence of Morals and Economics."

PROFESSOR G. W. OSBORN HOWE, "Recent Progress in Radio-Telegraphy."

E. D. MOREL, "British Rule in Nigeria."

GORDON CRAIG, "Stage Illusion."

THEODORE E. SALVESEN, "The Whaling Industry of To-day."

LEONARD HILL, M.B., F.R.S., and MARTIN FLACK, M.A., M.B., B.Ch., "The Influence of Ozone in Ventilation."

E. A. GAIT, I.C.S., C.I.E., Census Commissioner for India, "The Indian Census of 1911."

WALTER SAISE, D.Sc., M.Inst.C.E., F.G.S., "The Coal Industry and Collier Population of Bengal."

W. A. LEGG, M.Inst.C.E., "Irrigation in South Africa."

NEVILLE PRIESTLEY, Managing Director, South Indian Railway, "Indian Railways."

ALAN BURGOYNE, M.P., "Colonial Vine Culture."

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

January 18, February 8, March 14, April 25, May 16.

COLONIAL SECTION.

Tuesday afternoons, at 4.30 o'clock:—

January 30, February 27, March 26, May 7.

CANTOR LECTURES.

Monday evenings, at 8 o'clock:—

PROFESSOR VIVIAN B. LEWES, "The Carbonisation of Coal." Four Lectures.
November 27, December 4, 11, 18.

LECTURE I.—NOVEMBER 27.—*The Composition of Coal.* Existing theories on the composition of coal and the chemistry of its formation—Humus and resin compounds found in lignites, and the action of heat upon them—The classification of coals, and the effect of composition on the products of decomposition by heat—Coking and non-coking coals.

Hosted by Google

LECTURE II.—DECEMBER 4.—*The Methods Employed in the Destructive Distillation of Coal.* The changes which have taken place during the last century in the forms and settings of gas retorts—The developments of the last ten years and present position of the gas industry—The coke industry and the gradual development of the modern recovery plant—The influence of the retort or oven on the carbonisation.

LECTURE III.—DECEMBER 11.—*The Thermal Conditions existing during the Carbonisation of Coal.* The heat of formation of coal—The work of Euchene, Mahler, and others—The cause of the endothermic nature of some coals—The thermal value of the reactions taking place in the retort—The losses of heat in a retort setting—The transmission of heat through the retort and charge—The effect of temperature and travel on the primary products of decomposition—The temperatures existing in retorts and ovens—Small charges and full charges—The influences which lead to improvement in the product from full charges, chamber and vertical retorts.

LECTURE IV.—DECEMBER 18.—*The Possible Improvements in Carbonisation.* The aims of the gas manager and coke producer—Experiments on low temperature distillation and their teaching—The rivalry existing between fully-charged retorts, vertical retorts, recovery ovens, and chamber carbonisation—The intermittent vertical retort *versus* the continuous vertical systems—The Settle-Padfield, Duckham-Woodall, and Glover-West processes—The ideals of carbonisation—The volume of gas due to primary and secondary reactions—The gasification of tar—The limitations of volume and quality of gas—The ends to keep in view in devising new processes of carbonisation.

VAUGHAN CORNISH, D.Sc., F.G.S., F.C.S., "Ocean Waves, Sea-Beaches, and Sandbanks." Two Lectures.
January 22, 29.

LOUDON M. DOUGLAS, F.R.S.E., "The Meat Industry." Three Lectures.
February 5, 12, 19.

LUTHER HOOPER, "Hand-Loom Weaving." Three Lectures.
February 26, March, 4, 11.

NOEL HEATON, B.Sc., F.C.S., "Materials and Methods of Decorative Painting." Three Lectures.
March 18, 25, April 1.

HOWARD LECTURES.

Monday evenings, at 8 o'clock:—

CAPTAIN H. R. SANKEY, R.E., M.Inst.C.E., "Heavy Oil Engines." Four Lectures.
April 29, May 6, 13, 20.

JUVENILE LECTURES.

Wednesday afternoons, at 5 o'clock:—

CHARLES VERNON BOYS, F.R.S., "Soap Bubbles." Two Lectures.
January 3 and 10, 1912.

CONVERSAZIONE.

The Annual Conversazione of the Society will be held about the middle of June, 1912. Each member is entitled to a card for himself, and one for a lady.

PROCEEDINGS OF THE SOCIETY.

THE SOCIETY was founded in 1754, and incorporated by Royal Charter in 1847, for "The Encouragement of the Arts, Manufactures, and Commerce of the Country, by bestowing rewards for such productions, inventions, or improvements as tend to the employment of the poor, to the increase of trade, and to the riches and honour of the kingdom: and for meritorious works in the various departments of the Fine Arts; for Discoveries, Inventions, and Improvements in Agriculture, Chemistry, Mechanics, Manufactures, and other useful Arts; for the application of such natural and artificial products, whether of Home, Colonial, or Foreign growth and manufacture, as may appear likely to afford fresh objects of industry, and to increase the trade of the realm by extending the sphere of British commerce; and generally to assist in the advancement, development, and practical application of every department of science in connection with the Arts, Manufactures, and Commerce of this country." In 1908 the Society was granted by King Edward VII. the privilege of adding "Royal" to its title.

Hosted by Google

The Session commences in November and ends in June.

Ordinary Meetings.—Meetings are held every Wednesday evening during the Session, at which papers on subjects relating to inventions, improvements, discoveries, and other matters connected with the Arts, Manufactures, and Commerce of the country are read and discussed.

Indian Section.—This Section was established in 1869, for the discussion of subjects connected with our Indian Empire. Six or more Meetings are held during the Session.

Colonial Section.—This Section was formed in 1874 under the title of the African Section, for the discussion of subjects connected with the Continent of Africa. It was enlarged in 1879, so as to include the consideration of subjects connected with our Colonies and Dependencies. Four or more Meetings are held during the Session.

Cantor Lectures.—These Lectures originated in 1863, with a bequest by the late Dr. Cantor. Several Courses are given during the Session, each Course consisting of two or more Lectures. The Lectures deal with the latest applications of Science and Art to practical purposes, and are, as far as possible, experimentally illustrated.

Howard Lectures.—The bequest of Mr. Thomas Howard (1872) is now devoted to occasional courses of Lectures on motive power and its applications.

Shaw Lectures.—Under the Shaw bequest Lectures on Industrial Hygiene are given from time to time.

Aldred Lecture.—The bequest of the late Dr. Aldred has been devoted to the establishment of an Annual Lecture.

Cobb Lectures.—Funds have been provided for an occasional Lecture in memory of the late Mr. Francis Cobb.

Juvenile Lectures.—A Short Course of Lectures, suited for a Juvenile audience, is delivered to the children of Members during the Christmas holidays.

Admission to Meetings.—Members have the right of attending the above Meetings and Lectures. They require no tickets, but are admitted by signing their names. Every Member can admit *two* friends to the Ordinary and Sectional Meetings, and *one* friend to the Cantor and other Lectures. Books of tickets for the purpose are supplied to the Members, but admission can be obtained on the personal introduction of a Member. For the Juvenile Lectures special tickets are issued.

Journal of the Royal Society of Arts.—The *Journal*, which is sent free to Members, is published weekly, and contains full Reports of all the Society's Proceedings, as well as a variety of information connected with Arts, Manufactures and Commerce.

Examinations.—Examinations, founded in 1853, are held annually by the Society, through the agency of Local Committees, at various centres in the country. They are open to any person. The subjects include the principal elements of Commercial Education and Music. At the 1911 Examinations 28,644 Candidates were examined, at 459 centres. Full particulars of the Examinations can be had on application to the Secretary.

Library and Reading-room.—The Library and Reading-room are open to Members, who are also entitled to borrow books.

Conversazioni are held, to which Members are invited, each Member receiving a card for himself and a lady.

Membership.—Candidates for Membership are proposed by Three Members, one of whom, at least, must sign on personal knowledge; or are nominated by the Council.

The Annual Subscription is Two Guineas, payable in advance, and dates from the quarter-day preceding election or a Life Subscription of Twenty Guineas may be paid. There is no Entrance Fee

PROCEEDINGS OF THE SOCIETY.

FIRST ORDINARY MEETING.

Wednesday, November 15th, 1911; LORD SANDERSON, G.C.B., K.C.M.G., Vice-President and Chairman of the Council, in the chair.

The following candidates were proposed for election as members of the Society:—

Angel, Robert John, M.Inst.C.E., A.R.I.B.A., Town Hall, Spa-road, S.E.

Baildon, Arthur Edward, Yeo Cottage, 6, Yeo-street, Yeoville, Johannesburg, South Africa.

Bain, Professor Samuel M., University of Tennessee, Knoxville, Tennessee, U.S.A.

Banganapalle, The Nawab of (Nawab Saiyid Ghulam Ali Khan Bahadur), Banganapalle, India.

Beanes, Fred. E. V., 4, Morden-road, Blackheath, S.E.

Benson, His Honour Judge William Denman, 10, William-street, Lowndes-square, S.W.

Bhattacharya, Professor Saratchandra, M.A., F.C.S., St. Columba's College, Hazaribagh, Bengal, India.

Black, Professor Ebenezer Charles, LL.D., 50, Kirkland-street, Boston, Mass., U.S.A.

Bray, Henry Freer, 2, Kasumi-cho, Azabu, Tokyo, Japan.

Bremner, Alexander, 38, New Broad-street, E.C.

Bright, Alfred Ernest, 34, Queen-street, Melbourne, Australia.

Burnside, William, Assoc.M.Inst.C.E., c/o Messrs. MacBride, McGrouther & Co., 149, West George-street, Glasgow.

Butcher, Miss Anna Deane, c/o Dr. Bailey, Featherstone Hall, Southall, Middlesex.

Canjee, Sheriff D., 13, Cuffe-parade, Bombay, India.

Cantlie, James, M.A., M.B., F.R.C.S., D.P.H., 140, Harley-street, W.

Chowdhury, Brajendra Kishore Roy, Gouripore, Mymensingh, India.

Clare, George Herbert, P.O. Box 1194, Saskatoon, Saskatchewan, Canada.

Cocks, Robert Macfarlane, 24, Oakwood-court, Kensington, W.

Coen, Giorgio Silvio, San Polo, Palasso Bernardo 1978, Venice, Italy.

Cole, Harold Linter, c/o Messrs. King, King & Co., Bombay, India.

Corfe, Right Rev. Bishop Charles John, D.D., Church House, Dean's Yard, Westminster, S.W.

Cross, Malcolm, 1, Devonshire-gardens, Glasgow, W., and Carlton House, 11D, Regent-street, W.

Daniel, Captain F., Penang Pilot Association, Government Buildings, Penang, Straits Settlements.

Datta, Aswini Kumar, Barisal, Eastern Bengal and Assam, India.

Dickson, Charles Allan, Kadarma, E.I.R., India.

Douglas, Greville, 27, Wilton-crescent, S.W.

Dukoff-Gordon, Ronald, B.A., Germiston, Transvaal, South Africa.

Dutt, Ajit Kumar, Dilkusha, Bhowanipore, Calcutta, India.

Edgley, Sydney William, F.C.P.A., 20, St. George's House, 73, St. George's-street, Cape Town, and Rosebank, Cape Town, South Africa.

Ellahie, Abdur Raheen Buksh, 10, Colootolah-street, Calcutta, India.

Elliott, Dawson K., 35, Kennedy-street, Winnipeg, Manitoba, Canada.

Fitz-Gibbon, William Guerin, B.A., The China Mutual Life Assurance Co., Limited, Hangchow City, Chekiang Province, China.

Fletcher, A. Byers, D.D.S., 9, Park Mansions, Knightsbridge, S.W.

Gee, William James, 48, Kingsmead-road, Tulse-hill, S.W.

Gupte, Rai Bahadur B.A., F.Z.S., Indian Museum, Calcutta, India.

Hajime, Councillor Hodo, Kiobashi, Tokyo, Japan.

Hamilton, Professor George Hall, B.A., 12, Grove End-road, St. John's-wood, N.W.; and Bellevue College, Bellevue, Nebraska, U.S.A.

Hate, Professor Vinayak Nanabhai, B.Sc., Girgaon Back-road, Girgaon, Bombay, India.

Hewlett, William George, Box 3492, Johannesburg, South Africa.

Jackson, B. Leslie, A.R.C.A., Croft Lodge, The Park, Newark-on-Trent.

Jameson, Percy R., Taylor Instrument Company, Rochester, New York, U.S.A.

Jhaveri, Krishnalal Mohanlal, Girgaon Post Office, Bombay, India.

Lloyd, Charles Sidney FitzRoy, Custom House, Shanghai, China.

The Chairman delivered the following

ADDRESS.

I must begin by expressing my sense of the honour which my colleagues on the Council have done me in electing me to be their Chairman for the current year. I cannot refrain from adding an expression of my gratitude to Edward Henry, fifteenth Earl of Derby, a former Vice-President, who, knowing my propensity for science—and being desirous, as he said, of making an additional donation to the funds of the Society—proposed me thirty-two years ago for membership, and paid my life subscription. It was one of many acts of generous kindness for which I was indebted to him, and has procured me many hours of instruction from the Society's publications, though circumstances over which I had no control have prevented me from being a frequent attendant at its meetings.

There are one or two events which ought to be noticed at the beginning of our Session, though they have already found mention in the Council's reports. I have to congratulate the Society on the acceptance of the office of President by H.R.H. the Duke of Connaught. During the course of the summer his Royal Highness was good enough to show his interest in our proceedings by personally presenting to Sir Charles Parsons the Albert Medal of the Society which had been awarded to him. I think you will agree with me that our best thanks are due to Lord Alverstone for his acceptance and tenure of the office of provisional President during the interval of vacancy caused by the King's accession to the Throne. It has been a fresh instance of the efficient and valuable support which the Society receives from Lord Alverstone.

I have also to congratulate the Society on the completion of its new medal, bearing the effigy of King George. The portrait is a remarkable success, and has received his Majesty's gracious commendation.

Finally, I cannot omit to call attention to the five most interesting papers on the early history of the Society which have been contributed by our Secretary to its *Journal*. If for no other reason, I should prize them as explaining the meaning of the remarkable pictures which adorn our walls, and which have hitherto, I confess, been to me an object of admiring bewilderment.

I was in some perplexity as to the choice of a subject for the address which it is customary for the Chairman of Council to deliver at the opening of the Session. I found that my predecessors, as seems right and reasonable, had selected for their topics some branch of industry, art, or applied science, of which, in the course of their respective professions, they had been in a position to acquire intimate knowledge, and on which they could therefore speak with authority. But diplomacy, in the study and practice of which I have passed my life, though it is sometimes termed an art, can scarcely be included in the Arts which this Society was formed to encourage. Nor could I claim your attention for a disquisition on the methods of framing Protocols or on the cultivation of the very essential quality of holding one's tongue. I have thought, however, that it might not be uninteresting or unprofitable to examine briefly what is one of the most striking features of recent years—the immense development of international intercourse. It is a vast subject, on which a volume could easily be written, and with which I can only deal in a cursory and fragmentary manner. I do not think that many of us realise how much it enters into our daily lives. As Rousseau said, "It requires much philosophy to observe what happens every day."

And I should like to preface any attempt at systematic discussion of the subject by relating two somewhat trivial incidents which brought the matter home to me.

The first happened some four or five years ago. I was travelling on the Highland Railway in Sutherlandshire, and the train stopped for eight or ten minutes at a not very important station, in the manner with which travellers on that line are familiar, while the two engines went off to get a drink of water, and a sort of garden party took place on the platform. Just as the engines were returning refreshed, a young man advanced towards my carriage who appeared to be the embodiment of national industry and sport. He was dressed from head to foot in dark grey homespun; he carried in one hand what was obviously a rifle case, in the other he had a caddy-bag full of golf clubs, on his back were strapped a fishing-rod and gaff, at his side was a large fishing basket, round his waist was a long steel chain, at the other end of which was a magnificent retriever. A porter opened the door, the dog jumped in and at once lay down under the seat, his master got in after him and sat down with a thump, and all his accoutrements clattered round him. Then it occurred to him that he was not provided with luncheon. He took out sixpence, beckoned to a boy and bought a bunch of bananas. Those bananas had come from the West Indies, some five thousand miles away. I contrasted with this the doleful account given twenty years ago by a Roumanian gentleman of his travels in North Britain, how he had suffered the extremities of hunger, had rushed to a refreshment stall and taken away a small pie, and how on opening it he had found that it contained nothing but a bit of pig's ear, and I realised what improved communications had done for us.

The second incident occurred this summer. I was distributing to various friends a small book of children's stories, weighing just under eight ounces. The heat was so great that I preferred to send a copy by post to Belgrave Square instead of taking it myself. The postage cost twopence. I wished also to send copies to Denmark, Russia, and Japan. The charge for doing so was equally twopence, and if I had wished to send one to Timbuctoo, where not long ago Cassowaries were supposed to eat missionaries, with hymn-book sauce, but where there is now a regular French administration, the cost would still, I believe, have been twopence.

To turn to the wider aspects of the question, I will begin with that with which I am best acquainted, but which is not after all the most important—the growth of diplomatic intercourse. I am not going to drag you into an archæological dissertation, but it may be interesting to glance for one moment at the records which we have of such intercourse some 3,500 years ago. You will find in the Babylonian and Assyrian Room of the British Museum a whole series of small clay tablets, containing the instructions issued by Khammurabi, King of Babylon, about 2,000 years B.C., to his administrative officers in the provinces and cities under his rule, and in another case are preserved portions of a correspondence which took place some five hundred years later between Amenophis III., King of Egypt, and Kallimma Sin, King of Karaduniyash in Babylonia. It seems that Amenophis had married a sister of Kallimma-Sin, and was now making proposals of marriage for one of his daughters, named "the Little One," or, I suppose, "Tiny." The nature of Kallimma-Sin's reply may be gathered from the label attached to a further letter from Amenophis, of which Dr. Budge, the eminent head of the department, has kindly given me a copy.

"After salutations Amenophis refers to the refusal of Kallimma-Sin to give him his daughter in marriage, on the grounds that she is too young and is not beautiful, and in answer to Kallimma-Sin's complaint—that no one knows what had become of his sister, who had married Amenophis, or whether she was alive or dead—he invites him to send a wise man to see her and to report upon her health, the comfort in which she lives, and the honour in which she is held. If Kallimma-Sin will give Amenophis another daughter to wife, he will send him richer gifts than any prince of Karaduniyash could afford to give him. Finally, Amenophis expresses a wish that friendship may continue to exist between himself and Kallimma-Sin, and begs him not to believe the words of the Mesopotamian envoys, who have declared that they received no gifts from the King of Egypt, and in the matter of the chariots and horses, which Kallimma-Sin has asked to be returned to him, he declares that though they may have reached the frontier of Egypt, they have never entered the country."

In another portion of the correspondence, preserved in the Museum at Berlin, Kallimma-Sin claims matrimonial reciprocity, that Amenophis should send him an Egyptian princess to wife. Amenophis replies, with hauteur, that

Hosted by Google

it has not been the custom that princesses of Egypt should marry anybody or nobody. The unabashed Kallimma-Sin returns to the charge.

"Why not?" he writes. "Thou art King, and canst do as thou pleasest, and if thou shalt give her unto me, who shall say a word against it? Surely there be beautiful women in Egypt, and if thou knowest any such, send her to me—for who could say here that she is not a princess?"

I must not detain you longer over ancient history, in which I fear I am not a very competent guide, and will leap like a grasshopper over an interval of 3,000 years to the fifteenth century of the Christian era, when the maintenance of permanent diplomatic agents at foreign Courts, initiated some time previously by the Popes, became general in Europe, simultaneously with the establishment of permanent armies. Some cynical writers on international law have drawn the conclusion that these permanent missions were kept up quite as much for the purpose of watching the military progress of the various states, as for the maintenance of good relations. Certainly the ambassadors were not always very convenient guests. There is in the State Papers of Henry VIII. an elaborate account, sent to the European Governments, of the manner in which it was discovered that the Austrian Ambassador was intriguing for the overthrow of Wolsey, and a justification of the demand made for his recall. It would seem that a messenger charged with the Ambassador's despatches was found wandering about on his way to the ship that was waiting for him in the Thames, in a manner which suggests a London fog, and that, being unable to give an intelligible account of himself, he was arrested and his packets opened, in which such horrible things were discovered that they were at once sent to the Lords of the Privy Council. The Papal Legate succeeded in getting hold of and carrying off Henry VIII.'s love letters to Anne Boleyn, and they are now in the Vatican Library. In the reign of Queen Elizabeth, the Spanish Ambassador was sent back on a charge of conspiracy against the Queen's life, and in that of Charles II. a conflict took place between the French and Spanish Ambassadors as to the right of precedence in going to Court, in which shots were freely exchanged, five or six people were killed and thirty wounded.

The presence of a Russian Ambassador at the Court of Queen Anne is made memorable by the demand of Peter the Great for the heads of the sheriff's officers who arrested him for debt, and by the presentation in lieu thereof of the statute on diplomatic immunities, enclosed in a gold box.

Although Turkey was not formally admitted into the concert of European nations until the Congress of Paris in 1856, we had a British Ambassador resident at Constantinople as early as 1621. The first permanent Turkish envoy in London arrived in 1795.

The story of the progress of international relations with China and Japan is full of interest, but I can only briefly allude to one or two episodes. In 1793 Lord Macartney was sent on a special mission to the Emperor of China, and successfully evaded the demand that, on being admitted to the Imperial presence, he should perform the kotow, by offering to do so if a high Chinese official would go through the same ceremony before a picture of George III. The result was that he was allowed to kneel on one knee in the manner obtaining at the English Court. But the Chinese Court records omitted all mention of this modification, and when Lord Amherst was sent on a similar mission in 1816, the demand for the performance of the kotow was renewed. As Lord Amherst persistently refused, he was sent back without an audience, the Prince Regent's letter was returned unopened, with most of the presents, and a letter was addressed to the King of England by the Emperor giving his account of the circumstances in a tone which throughout assumes that the embassy was one from a subordinate Sovereign, and charged with tributary offerings. It is too long to quote, but the sting is in the tail, which is as follows:—

"The Celestial Empire does not value things brought from a distance. All the extraordinary and ingenious productions of your country also it does not look upon as rare pearls.

"That you, O King, should preserve your people in peace, and be attentive to strengthen the limits of your territory, that no separation of that which is distant from that which is near should take place, is what I, the Emperor, in truth highly commend.

"Hereafter there is no occasion for you to send an Ambassador so far, and to be at the trouble of passing over mountains and crossing seas. If you can but pour out the heart in dutiful obedience, it is not necessary at stated times to come to Court, e'er it be pronounced that you turn towards the transforming influences which emanate from this land.

Hosted by Google

"This Imperial mandate is now given that you may for ever obey it."

Thenceforth, it may be said in general terms that when our envoys went on special missions to Pekin, they usually did so with an expeditionary force at their backs, until the establishment there of a resident Minister in the person of Sir Frederick Bruce in 1860. The first regularly accredited Chinese Minister, Kwo Tajen, came here in 1877. Almost immediately after his arrival he was entertained at a large dinner party at the Foreign Office. I sat close to him, and I still have a vivid recollection of the expression of his face as he chewed and swallowed a large piece of lemon which had been handed to him to squeeze into his turtle soup. He remarked very courteously, when I explained his mistake, that it was not the best thing he had eaten since his arrival in England.

Our first permanent envoy to Japan was appointed in 1859, and the first Japanese Minister was received here in 1875. I remember the arrival of a previous Special Mission in 1867, escorting a young brother of the then reigning Tycoon — an intelligent, attractive boy. I was present at their interview with Lord Stanley, then Foreign Secretary. The conversation turned on the fire which destroyed His Majesty's Opera House in the Haymarket, and which the Mission had seen from the windows of their hotel. The Tycoon's brother made an observation which elicited a general laugh from his suite and which was interpreted, "He says, my Lord, that they have a fire as big as that in Japan nearly every day."

As regards the increase in the amount of business transacted by the Foreign Office, my statistics go back no further than 1826, but they are sufficiently remarkable. The total number of despatches received and sent in the year at that period averaged 11,000. It steadily increased to 30,000 in 1849. After an abnormal increase during the Crimean War, it steadied down to 50,000 in 1860. It was over 70,000 in 1880, and in 1900 it stood at 100,000—since which there has been a further gradual increase.

I reserve to the conclusion of my address a remarkable feature of recent diplomatic intercourse in which the Society has been more actively interested. In the meanwhile, let us turn to other matters in which it has taken a not unimportant part.

And first, as regards the growth of our postal communications with foreign countries and the oversea parts of the Empire. In 1619 a separate office of Postmaster-General of England for foreign parts was created by letters patent in favour of a certain Matthew de Quester and his son, who in 1633 transferred it to William Frizell and Thomas Witherings. The latter appears to have been the first of our postal reformers, and entered into a contract with the Count of Turn and Taxis, hereditary Postmaster of the Empire and of Spain, for the acceleration of the Continental mail service. There was at that time only one mail weekly between London and the Continent, *via* Antwerp and Brussels, and the transit occupied from four to five days. By a subsequent contract two mails weekly were secured, and the transit made ordinarily in two days. In 1819 there were still but two mails a week to the Continent *via* Calais, Ostend, or Helvoetsluys on Tuesday and Friday; to Portugal once a week only from Falmouth; to the Mediterranean, the West Indies, and South America once a month, also from Falmouth.

I have seen somewhere an enthusiastic description of the seven fine cutter-rigged packet-boats kept at Dover for the service across the Channel. No use was made of steam navigation for the packet service till 1821.

Contrast this state of things with the present organisation in which the Post Office issues in October a long table of the dates at which letters and packets should be posted in order to reach the most distant parts of the globe by Christmas and New Year's Day, and when, as I have told you, a small book-packet can be sent almost everywhere short of the moon for the same charge as to another part of London.

Statistics on such subjects run into such stupendous figures that they produce a feeling of bewilderment. The weight of correspondence in letters, postcards, printed and commercial papers and samples, exchanged by the United Kingdom with foreign countries and British colonies during the year 1910, is given in the last report of the Postmaster-General as eleven and a half millions of pounds avoirdupois, and the number of parcels as over five millions.

On the subject of the development of telegraphic communication, and of the part taken in it by the Society, you had an address last year from my predecessor, and I will not venture to intrude on the domain in which he has ruled supreme. I will only quote to you an instance of the effect it has had in facilitating international commercial transactions which is given by Mr. Wells in his book on "Recent Economic

Hosted by Google

Changes." It happened in 1884. An eminent merchant of Boston, before starting with Mr. Wells on a journey from New York to Washington, telegraphed to his agent in Calcutta to buy hides and gunny bags if procurable at a certain price, and to charter a ship for their conveyance if one could be found. On his arrival at Washington, a telegram from the agent was put into his hands stating that the goods had been purchased, the vessel chartered, and that loading had begun.

I believe that nowadays, by means of what are profanely called Macaroni-grams, such transactions can be commenced and completed in the course of a five days' passage across the Atlantic.

It may, perhaps, amuse you to hear of the struggles which we made at the Foreign Office to keep down the expenditure in telegrams, which rose from £3,000 in 1869–70 to £20,000 in 1879–80; and in 1900–1, owing to adverse circumstances, reached a maximum of £55,000. Since then it has been considerably reduced, partly, no doubt, in consequence of the lower rates of charge, partly because our Agents have acquired the art of condensing. It takes some time, as the late Lord Salisbury said, to learn to write Telegraphese, and some people cannot acquire the art. I was a good deal relieved to find at our worst moment that the expenditure of the Japanese Government under this head was so much greater, that our charge appeared a mere flea-bite in comparison.

As regards facilities for travel by sea, you need only read Charles Dickens' account of his fifteen days' passage on the mail steamer to Halifax in 1842, and compare it with the voyages now made by the huge floating palaces which run to New York.

The contrast is perhaps even more remarkable on land. Gibbon relates in the second chapter of his great work, that the chain of roads in the time of the Roman Empire reached from York to Jerusalem through Rome and Constantinople —a distance of 3,740 English miles, broken only by two short sea passages from Sandwich to Boulogne, from Brindisi to Durazzo—that post-houses were established at intervals of five or six miles and constantly provided with forty horses, and that by means of these relays it was easy to travel a hundred miles a day. Julius Cæsar has the reputation of having achieved something not far short of this. But the ordinary rate of travel scarcely exceeded twenty to thirty miles a day, and after the break-up of the Roman Empire no such continuous journey was possible. In 1834, Sir James Hudson, travelling night and day with the summons from King William IV. to Sir Robert Peel to form a Government, accomplished the journey from London to Rome in nine days. Sir Robert and his family, travelling, as Mr. Justin McCarthy remarks, from Rome to London in exactly the same way as Constantine had travelled from York to Rome 1,500 years before, reached their destination in twelve days, having halted on four nights only, because they could not get on. The time now allowed for the journey is under forty-eight hours.

It is calculated that in 1840 there were in Europe and America only 5,000 miles of railway in operation. In 1885, the number of miles was probably about 300,000; it is estimated as amounting in 1906 to 578,000 miles.

On the growth of commercial intercourse, I have some very convincing statistics to offer you. In 1906 a paper was laid before Parliament giving the total value of imports and exports for eleven principal European countries and the United States in 1854, and every succeeding tenth year down to 1904, and my friends at the Foreign Office, who are always kind to me, have added the figures for Italy and for the year 1910. I will be merciful to you, and leave you to study this paper as an appendix to my address in the *Journal*. I am not concerned with odious comparisons as to the rates of increase in different countries, it is sufficient for me that that increase is general, and I will only tell you that the net imports of the United Kingdom have risen in value from £134,000,000 in 1854 to £575,000,000 in 1910, and the exports from £97,000,000 to £430,000,000, an increase of over 300 per cent. in each case, while the population has increased by about 70 per cent. only.

As an indication of the increased comfort which this progress has brought with it, it is interesting to notice that the imports of butter have risen in value from £15,000,000 in 1896 to £24,500,000 in 1910, and of eggs from £4,000,000 to £7,000,000. Or, if you prefer the quantities, the amount of imported butter retained for use in the United Kingdom has risen from 3,000,000 cwts. to 4,500,000 cwts., and the number of eggs from 1,000 millions to 2,000 millions.

I come finally to what seems to me the most notable feature of recent international intercourse, and that in which this Society is most interested—the great increase in international

Hosted by Google

FOREIGN TRADE (COMPARATIVE GROWTH).

Total Imports and Exports (Special Trade) for each of the years 1854, 1864, 1874, 1884, 1894, 1904, and 1910 (so far as the information can be given), of the following thirteen Countries, viz.:—1. France; 2. German Zollverein and German Empire; 3. Belgium; 4. Netherlands; 5. Russia; 6. Austria-Hungary; 7. Denmark; 8. Sweden and Norway; 9. Spain; 10. Portugal; 11. United States; 12. United Kingdom; 13. Italy.

NOTE.—Special Exports are Exports of Domestic Produce or Manufacture. In the cases of Sweden and Spain the figures given as "General Exports" include, besides the exports of domestic merchandise, a certain quantity of foreign merchandise previously imported.

1 Particulars of the "Special" Exports of Spain are not available before 1888. The "Special" Exports amounted to £25,137,000 in 1894, to £35,640,000 in 1904, and to £38,234,000 in 1910.

2 Including Venetia and Mantua.

3 In 1851. The value of Bullion and Specie is included.

4 In 1866, the first year for which Returns of Special Trade are available.

5 In 1865. Returns of Special Trade for the year 1864 are not available.

6 Excluding Venetia, Roma, and part of Mantua.

7 Including Silver Bullion.

8 Including the value of the Improvement Trade for Home Account (£5,013,000), and also the value of ships (£520,000). These items have only been included in the German Returns of Special Trade since 1897.

9 Including the value of ships and boats (new) with their machinery exported, which amounted to £4,455,000 in 1904, and to £8,770,000 in 1910. These items have only been included in the Trade Returns of the United Kingdom since 1899.

10 In 1909, the latest year available.

11 Provisional figure. In 1909, the latest year available.

exhibitions, associations and conferences of every description, and on every conceivable subject. When I first joined the Foreign Office, rather more than fifty years ago, conferences were confined almost entirely to formal diplomatic meetings to settle some urgent territorial or political question in which several States were interested. At rare intervals, and on some occasion of paramount importance, a congress was held, the name implying that, instead of sending ordinary plenipotentiaries, the States concerned were represented by their Foreign Ministers or persons of equal standing. Of these latter only one, the Congress of Berlin, has been held during my period of service. But as time has gone on, not only have the number and frequency of political conferences increased, but a host of meetings of personages more or less official, termed indiscriminately conferences and congresses, have come into being. The International Exhibition of 1851 was so great an event that there was an inclination on the part of many sanguine people to believe that it would inaugurate an era of universal peace. That illusion was speedily dispelled, but international exhibitions were repeated at regular and stated intervals. Then came a sudden boom in exhibitions, and now it seems to me that there is always an international exhibition of something going on somewhere. The last variety that has come into notice is an International Field Sports and Shooting Exhibition, held at Vienna in 1910, of which a report has just been laid before Parliament.

These exhibitions seem to breed congresses. At the Paris Exhibition of 1900, an official list was presented of no less than 105 international congresses which it was proposed to hold on various subjects. Actuarial matters, aeronautics, agriculture, Alpinism, anthropology, societies for the blind, botany, bakery, chemistry, railways, popular credit, dentistry, maritime law, electricity, rights of women, geography, geology, head the alphabetical French list—you will not ask me to complete it.

There are certain official international conferences which meet regularly at stated intervals, among the most important of which are that for the revision of the Geneva Convention for the Care of the Sick and Wounded in War, that for the discussion of the arrangements respecting bounties on sugar, those on postal arrangements, telegraphs, wireless telegraphy, the North Sea fisheries. There is a permanent international tribunal at the Hague, ready at any time to hear and decide international disputes, and there are permanent international bureaux on agriculture, copyright, geodesy, health, industrial property, maritime slave trade, the metric system, navigation, the North Sea fisheries investigation, posts, railways, telegraphs, sugar bounties, sleeping sickness, and customs tariffs, to all of which the British Government contributes.

How different is this from the view of Cicero that the southern zone bore absolutely no relation to the condition of Europe, that even Europe had very little interest in the eyes of the humane world of Italy, that it was unimaginable that even the mightiest name from lands of civilisation and culture should pass the eternal barriers of Caucasus or be wafted over the Ganges.

How antagonistic to the spirit of the Turkish Cadi, who wrote to Sir Henry Layard in reply to a request for statistics, "My illustrious Friend and Joy of my Liver, the thing that thou askest is both difficult and useless," and added, "Of a truth thou hast spoken many words and there is no harm done, for the speaker is one and the listener is another. After the fashion of thy people thou hast wandered from one place to another, until thou art happy and contented in none. We (praise be to God) were born here and never desire to quit it. Is it possible then that the idea of a general intercourse between mankind should make any impression on our understanding? God forbid!"

The movement is, to put it shortly, a general tendency to resort to combination—to combined action—as a supplement to and, in some cases, as a substitute for competition. How far the process can be carried without impeding instead of promoting our advance, is one of the problems with which this age has to deal. It seems to be a law of nature that progress should be the outcome of unrest, of the production of an infinite variety of types in an infinite diversity of circumstances, and the survival of those which best bear the test. We can interfere to mitigate the harshness of the operation of the law of nature, but we cannot alter the law itself.

In science, international co-operation has already done much to extend our sphere of knowledge, especially in astronomy, meteorology, and the various questions connected with the conformation and behaviour of the crust o the earth. The charting of the heavens has been apportioned among the observatories of the world. I believe the Greenwich Observatory

Hosted by Google

has been commissioned in some special way to keep an eye on the moon, and the tremendous compliment has been paid to us of adopting the Greenwich meridian as the basis of all nautical calculations. Nations have combined to measure degrees of longitude, no comet or astronomical phenomenon is discovered, no earthquake can occur without being the subject of concurrent observation in the most distant parts of the globe. Our knowledge of nature becomes daily wider and more accurate. But the highest mysteries still remain insoluble. Finiteness and Infinity, and, with all due deference to Sir Oliver Lodge, the Ether of Space, remain as inconceivable as ever. We cannot loose the bands of Orion nor bind the sweet influences of the Pleiades.

Politically, the occasions for international disputes have perhaps increased. I have sometimes been appalled to find how no change can take place even in the remotest regions without some British toe being trodden on. But international dependence undoubtedly exercises an increasingly deterrent effect on the tendency to push such differences to extremes, or to resort to the arbitrament of war. I do not yet see the time when wars will altogether cease. That would imply that nations, which are but congregations of individuals, would cease to lose their tempers, and human nature does not change so quickly. But the times of the Truce of God, when fighting was strictly prohibited between Saturday evening and Monday morning, so that the general public might at least have a peaceful week-end—the later age, when, as Bacon puts it, "a just and honourable war" was regarded as "the true exercise of a Kingdom or Estate," when there was almost always a war going on somewhere in Europe to which a young man of spirit could go to win his spurs—these have passed away. War has come to be regarded more and more as a calamity to be avoided, whenever there is any alternative which both parties can reasonably accept.

Socially, it may be said that a general community of interest has come to be recognised throughout the world, that no serious trouble can occur anywhere without efforts being made to relieve it, and that the means of relief are far more efficient than hitherto. This improvement is indeed sometimes a little too evident to persons of moderate means, for no earthquake, famine or pestilence can take place in the outskirts of the habitable globe for which one does not receive an appeal for charitable contributions.

Finally, as regards the intellectual and moral result of our progress, I do not think it can be said that keener intellects, greater wisdom, or more exalted characters can be found in recent times than antiquity has produced. But surely we can claim that the great mass of population in civilised countries are leading, I will not say happier lives—for the elements and conditions of human happiness seem to me an enigma—but lives in the average healthier, longer, more free from hardship, more intelligent and more refined. Our high-water mark remains stationary, but we may hope that the low-water mark tends constantly to rise.

Such, as it seems to me, are the aims and results of work in which this Society has taken a not unimportant share. It has tugged for many years at the labouring oar, it has now the full tide with it. It has still, I feel sure, a useful and honourable part to play, but if I may venture to make a suggestion, I should say that our future work will lie less in the province of stimulation than in the exercise of discrimination and guidance—in pointing out the soundest methods, and selecting the most promising subjects. For this task, with its Committees of Indian and Colonial experts, the Society is very well equipped. We have ample scope, but we must avoid, in the American phrase, spreading ourselves out too thin.

I will ask permission to add one word of apology. I have been begged by one of my colleagues not to omit an exhortation to members to attend our meetings, to bring friends, and to enlist recruits, of which the Society is in constant need. I thought the best method of introducing such a request was to make my discourse as entertaining as lay within my power, and if some portions of it have seemed rather discursive and trivial, you must attribute this failing to my desire to enliven it.

After delivering the Address, the Chairman presented the medals awarded by the Society during last Session.

FOTHERGILL MEDALS (for Mine Rescue Apparatus).

A gold medal to Mr. H. A. FLEUSS, for the apparatus submitted by Messrs. Siebe, Gorman & Co.

A gold medal to Mr. W. E. GARFORTH, in recognition of his efforts to perfect and to secure the adoption of rescue apparatus in mines.

A silver medal for the "Meco" apparatus submitted by the Mining Engineering Company.

Hosted by Google

MEDALS FOR PAPERS.

At the Ordinary Meetings:—

To Mr. CAMPBELL P. OGILVIE, "Argentina from a British Point of View."

To Mr. VAUGHAN CORNISH, D.Sc., F.G.S., F.C.S., "The Panama Canal in 1910."

To Mr. REGINALD A. SMITH, B.A., F.S.A., "A New View of Roman London."

To Mr. PHILIP JOSEPH HARTOG, M.A., B.Sc., "Examinations and their Bearing on National Efficiency."

To Mr. GEORGE A. STEPHEN, "Modern Machine Bookbinding."

To Dr. LEONARD HILL, F.R.S., "Caisson Sickness and Compressed Air."

To Mr. JAMES CANTLIE, M.A., M.B., C.M., F.R.C.S., D.P.H., "Plague and its Spread."

To Mr. GEORGE B. HEMING, "Art Education in the Jewelry, Goldsmithing and Allied Trades."

To Professor RAOUL PICTET, "Les Basses Températures."

To Mr. FRANK M. ANDREWS, "Architecture in America."

In the Indian Section:—

To Mr. ROBERT FELLOWES CHISHOLM, F.R.I.B.A., F.S.A., "The Taj Mahal and its Relation to Indian Architecture."

To Mr. REGINALD MURRAY, "Banking in India."

To Mr. CLAUDE HAMILTON ARCHER HILL, I.C.S., C.S.I., C.I.E., "Education in India."

To Sir THOMAS HENRY HOLLAND, K.C.I.E., D.Sc., F.R.S., "The Trend of Mineral Development in India."

To Mr. W. R. H. MERK, C.S.I., LL.D., "The North-West Frontier Province of India."

In the Colonial Section:–

To Mr. A. MONTGOMERY, M.A., F.G.S., "The Progress and Prospects of Mining in Western Australia."

To Mr. F. DOUGLAS OSBORNE, M.Inst.M.M., "The Tin Resources of the Empire."

To Captain R. MUIRHEAD COLLINS, R.N., C.M.G., "The Commonwealth of Australia."

To Mr. F. WILLIAMS TAYLOR, "Canada and Canadian Banking."

SIR JOHN CAMERON LAMB, C.B., C.M.G., said that as the humble predecessor of Lord Sanderson in the chair, it gave him great pleasure to move a vote of thanks to Lord Sanderson for his address. In the present Chairman the Society not only had a man greatly distinguished in the public service of the country, but it had a working man, one who, before he became Chairman, took great interest in the work of the Society, and showed that interest in a practical way, and who now was conducting the meetings in the most admirable and prosperous manner. He (Sir John) thought all must feel, after hearing the humour which had characterised the address, and the genial way in which he had unbent before them, that Lord Sanderson had contributed very much, when he was in permanent charge of foreign affairs, to the harmony of nations. There was only one thing which he (Sir John) would like to mention, as illustrating the address and the extraordinarily sensitive relations which one part of the world had to another. Last summer he happened to visit an unimportant wireless telegraph station on the coast of Norfolk, and there he heard the Seewarte at Hamburg—the Greenwich Observatory of Germany—giving warning that it was about to distribute German time, and, after a minute or two, at that little place on the Norfolk coast, the Seewarte was heard giving German time. He had the greatest pleasure in moving a very cordial vote of thanks to Lord Sanderson for his charming address.

SIR STEUART COLVIN BAYLEY, G.C.S.I., C.I.E., in seconding the proposition, said he recalled the time when he had deprecated very strongly the custom of the Society requiring its Chairmen of Council to deliver an address as soon as they received the honour of that office. He was bound to add, however, that that was when he himself was Chairman! Now, however, he completely withdrew his objection, and after hearing what Lord Sanderson had been good enough to contribute in his initiatory address, he hoped the rule would remain in force, and that all future Chairmen would give the members an equally pleasant evening. He fully endorsed what Sir John Lamb had said with regard to the advantages the Society would derive from having a Chairman like Lord Sanderson.

The motion was put and carried unanimously.

LORD SANDERSON, in acknowledging the vote, said he would do his best in carrying out the duties of his office, and he only hoped he would not disappoint the members.

AGRICULTURAL WEIGHTS AND MEASURES.

In the course of a paper recently read by Mr. C. Kains-Jackson to the Farmers' Club on "The Metric System as applied to Agriculture," and the subsequent discussion thereon, attention was drawn to some of the anomalies in the systems of weights and measures from which agriculturists in this country suffer. Thus the barn gallon, by which milk is commonly sold, is equal to 2⅛ gallons. The great hundred, which prevails in the egg and timber trades, is 120. In Glasgow the stone is 22½ lbs., the half-pound (as Mr. Kains-Jackson

Hosted by Google

suggests) being apparently a bonus to help the Glaswegian to attract custom from Edinburgh, where the stone is 22 lbs. A quarter of linseed from India, if Bombay shipped, is 416 lbs.; if Calcutta shipped, is 410 lbs.; if bought in Mark Lane, it is 496 lbs., but if bought in cargo it is 492 lbs.

As showing the difficulty of seeing at once the respective values of eggs, a case was taken from the weekly returns of the Board of Agriculture: "Best new laid eggs, London, 1*s.* 6*d.* per dozen; Irish "first" eggs, London, 11*s.* 6*d.* per great hundred; French best eggs, London, 12*s.* per great hundred." It requires a mathematical calculation to discover that the prices of these eggs are respectively 1·5*d.*, 1·15*d.*, and 1·2*d.* each.

Some instances of the useless and irritating multiplication of measures were given by Mr. John McLaren of Leeds. "It seems anomalous and ridiculous at this time of day," he said, "that we should be selling wheat in Doncaster by the load, in Cambridge by the coomb, in Newcastle by the boll; that pits should be sunk in Northumberland by the fathom; that wool should be sold in Scotland by the tod, and beet by the Dutch stone . . . I remember when I went to Yorkshire first, I lived in the middle of the clothing district, where everything was spoken of by yards, and if you asked a man how tall his brother was he would tell you he was 'two yards but an inch.'"

Another speaker, Mr. Alfred Blomfield of Halstead, expressed a strong conviction that "there is no body of men anywhere who are so behind the times and so muddled up as regards sale transactions as farmers. Only to-day I have been on Mark Lane and have bought three different cereals. I bought barley at 25*s.* 6*d.* a quarter, I bought maize at 30*s.* 3*d.* a quarter, and I bought gram at 30*s.* 6*d.* a quarter. Can anyone tell me which is the cheapest corn I have bought there to-day? My barley, which I bought at 25*s.* 6*d.*, works out at £7 2*s.* 6*d.* per ton; the maize, which I bought at 30*s.* 3*d.*, works out at £7 1*s.* 3*d.* per ton; whereas the gram, which cost me 30*s.* 6*d.*, works out at £6 15*s.* 6*d.* per ton, so that the one I gave the most for per quarter was the cheapest per ton." Mr. Blomfield also told of an attempt which he himself had made to institute a small measure of reform. For some months he tried to sell his wheat, barley and oats by the hundredweight, but he found the merchants so difficult to deal with that he had to fall back on the old system. "Now," he continued, "we sell our barley at practically per hundredweight. We sell it at 16 stone per sack, which is two hundredweight. Why should we not sell our wheat and beans in the same way? We sell our beans 19 stone per sack, whereas if we buy maize we only get 17 stone 2 lbs., and if you buy from a middleman you probably only get 17 stone. If we sell our milk below standard we are liable to prosecution, but I believe it is considered perfectly legitimate for a man to buy maize at 17 stone 2 lbs., to take 2 lbs. out of the sack and still sell it as if 17 stone per sack were the proper weight." Matters are further complicated by the fact that standards vary in different markets. Thus, when Mr. Blomfield recently bought some seed wheat at Birmingham, he was under the impression that he was buying it at 18 stone. He found out afterwards that, as the weight of the sack was included, he only got 17 stone 10 lbs. Every sack of wheat was thus 4 lbs. short, but as that was the standard at Birmingham he could make no complaint. Other examples were mentioned by other speakers. In Worcestershire plums are sold by the "pot" of 72 lbs., in Middlesex and Kent by the half bushel, which is sometimes 28 lbs. and sometimes 24 lbs. In the case of apples you are supposed to get 40 lbs. to the bushel, but with some kinds you get more and with others less. Lettuces again are sold by the score, but here a score means not 20 but 22.

The whole meeting was very interesting, and illustrated in a remarkable way the incredibly complicated system of our agricultural weights and measures. It may be true that we are not the only nation that labours under disadvantages of this kind—that in Hungary, for instance, the farmer has a big *joch*, which means 3,200 square metres; a little *joch*, which means 2,400 square metres; and a catastral *joch*, which means about 4,000 square metres; and that in Germany the scientifically termed hectare is invariably transformed into the national *morgen;* but it is poor consolation to us to know that other people are suffering, in greater or less degree, from our own complaints. No doubt, the survival of these old-fashioned measures proves that they are for many purposes practically convenient—otherwise they would have vanished long ago; but the farmers present at this meeting seem to have been clearly of opinion that the time has come when some attempt should be made to simplify our system of weights and measures, and although it is notoriously difficult to change customs, however irrational they may be, which have received the sanction of a long tradition, still it should not be beyond the wit of man to discover some means of reforming a system, which must hamper agricultural transactions in a serious and quite unnecessary manner.

HOME INDUSTRIES.

Machinery Exports to the British Dominions.—Remembering how largely Germans control the mining industry in South Africa, it is a little surprising that German exports of machinery to the Union of South Africa are not greater than they are. The total value of the machinery imported by the Union from all sources in 1909 was £2,150,000, and last year £3,761,500. Of this total (for 1910) the United Kingdom supplied 63·9 per cent. and Germany, which came next, only 20·8 per cent., a percentage that would have been considerably less but for the arrangements made with German manufacturers in connection with the

Hosted by Google

scheme for the utilisation of the Victoria Falls and other electrical power schemes in the Transvaal. The electrical machinery imported by the Union in 1910 was of the value of £800,000 and it is to be noted that Germany sent by far the larger proportion of it, her figure being £480,000, the United Kingdom coming next with £251,000, and the United States third with £68,500. The British Crown Colonies and Dependencies have an area of over 1,100,000 square miles, and a population of about 33,000,000. Their imports of all kinds of machinery in 1909—the latest year for which the complete returns are available—were valued at £1,123,822, of which £877,229 came from the United Kingdom, 20 per cent. of the remainder coming from foreign countries. Geographical conditions have a good deal to do with foreign competition. For example, in the West Indies the competition is overwhelmingly from the United States, and to Jamaica the United States sent £21,620 worth of all the machinery imported from foreign countries, valued at £22,820. On the other hand, the theory that trade follows the flag is not supported by Mauritius, an island overwhelmingly French, yet taking more machinery from Germany than from France and England put together. In 1909 India took 48 per cent. of the machinery sent by the United Kingdom to the British Dominions overseas, or nearly as much as all the other British possessions put together. Her purchases of machinery of foreign manufacture did not exceed 5 per cent. of the whole. The total value of the machinery imported into India in the year ended March 31st, 1910, was £5,637,823, and of this the machinery of British origin represented £5,301,166, or 94·1 per cent., machinery of other origin £336,657, or 5·9 per cent. only. The chief of our foreign competitors was the United States, which sold India machinery to the value of £136,298, followed by Germany with a value of £71,371, but some of the machinery under the head of the Netherlands, Belgium, and Austria-Hungary was probably German, but even if it were all German only about £46,000 would have to be added to the German total. The present position of the United Kingdom in relation to its exports to British possessions overseas cannot be said to be unsatisfactory.

Short Time in the Cotton Trade.—There is good reason to hope that the conditions of trade will now enable the cotton mills to run full time. A fall of 2½*d.* per lb. means £100,000,000 on the average cotton crop of the world, and must have a very marked effect upon the consumption of manufactured goods and the consequent employment of the mills. Enhancements in the price of the raw material seriously affect all cotton manufacturing centres, but more especially England, owing to her great export trade to the Far East, where the purchasing power of the people is very limited. The other cotton manufacturing centres are engaged mostly in supplying the requirements of their home consumers, whose purchasing power is less restricted. It is noteworthy that of late years, since 1904, when the International Cotton Federation was established, foreign countries have co-operated in the policy of short time as far as their organisations and conditions admit, a policy which, as Sir C. W. Macara demonstrated anew the other day, has averted great disasters. "There is no doubt about this," he said: "if during the recent years of short supplies of cotton we had had unrestricted working, disasters of incalculable magnitude would have befallen the trade. We should have had many more failures or liquidations, and we might have had periods of complete stoppage, during which the sufferings of the workpeople would have been acute."

The Miners' Unrest.—The refusal of the Scottish mineowners to consider the miners' demand for a minimum wage increased the probability of a national stoppage in the coal-fields, but happily the representatives of the coalowners of England and North Wales at the Conciliation Board have since conceded the principle of the minimum wage, and promised to recommend it to their various districts. The Board thereupon adjourned until December 6th, and probably there will be further adjournments and meetings until a settlement is reached. It is true that this only applies to England and North Wales, and there remain South Wales and Scotland, but even there the owners are willing to enter into negotiations for the minimum wage in "abnormal places," and, anyway, the yielding of the owners' representatives in England and North Wales will make a general strike much less likely, and it is the contention of the employers that the men cannot declare an immediate general stoppage without violating their agreements. In the case of the Midlands district, which includes Yorkshire, Lancashire, Cheshire, Derbyshire, Staffordshire, Nottinghamshire, and the Forest of Dean, the conciliation agreement, subject to reservations of a technical nature, can be terminated at three months' notice. In Scotland the existing agreements have another year to run, and in Wales over three years. The contention of the employers is that until these agreements expire no question involving a change in wages can be discussed. This, however, is disputed by the men, who claim that this question of a minimum wage is one outside the scope of existing agreements.

Trailer Tramcars.—Although it is understood that the London County Council intend to apply for Parliamentary powers to attach trailer-cars to their trams, at least in the rush hours, it may be doubted whether, should Parliament consent, these trailers will do much towards solving the traffic problem. Trailers are common on the Continent and in America, but they have not done much towards meeting the rush traffic, and there are various objections to their use. The police do not like them on the ground that they are dangerous and obstruct the streets, dangerous owing to the

Hosted by Google

inferior control which generally results, and to the greater risk of injury to passengers boarding or leaving the cars if the driver receives the signal to proceed when only one car is ready to move. Then, the trailer reduces the rapidity of transit so much to be desired during the rush hours, and although it increases the carrying power it reduces the economic value of the tramway. The only real solution of this rush traffic problem would seem to be higher speeds and a more frequent service.

Employers' Liability Insurance Losses.—Figures issued by the Board of Trade, and covering fifty-six insurance companies, show that last year employers' liability business meant heavy loss to these companies. The total premiums earned amounted to £2,272,763; these figures represent the net premiums received during the year, plus the amounts reserved from the preceding year's premiums on account of unexpired liability, less the corresponding amounts reserved in respect of the current year's premiums. Losses are given at £1,649,537, an amount equal to 72·58 per cent. of the premiums; and commissions and expenses together are given at £816,307, which is equivalent to 35·91 per cent. of the premiums. The total loss on trading account for all companies is £193,081, which is equivalent to 8·49 per cent. of the premiums. Thirty-four of the companies included conduct their business on tariff lines, while twenty-two are non-tariff. The premiums earned during the year by the thirty-four tariff companies amounted to £1,985,325, on which a loss of £94,532, or 4·77 per cent. of the premiums, was incurred, and the premiums earned by the twenty-two non-tariff companies amounted to £287,434, in respect of which the loss on the year's trading was £98,549, or 34·28 per cent. of the premiums.

OBITUARY.

ALBERT HARRISON, F.C.S.—Intimation has been received of the death of Mr. Albert Harrison, which took place on August 28th. He was born in 1860, and after being educated at the Liverpool Institute he entered the laboratory of Messrs. Henry Tate and Sons' sugar refinery in Liverpool. In 1878 he was transferred to the London branch, of which he rose to be manager. He was a Fellow of the Chemical Society, a member of the Society of Chemical Industry, and of a large number of other scientific societies. He was well known as an entomologist, and for the statistical accounts of the results of breeding experiments which he conducted with British lepidoptera. He became a member of the Royal Society of Arts in 1886.

MASACHIKA SHIMOSÉ.—Mr. Masachika Shimosé, of Tokyo, died on October 6th, at the age of fifty-two. After graduating at the now defunct Imperial College of Engineering in 1884, Mr. Shimosé spent three years at the Printing Bureau, where he superintended the manufacture of printing ink and pigments. In 1887 he was transferred to the Naval Arsenal. Here he devoted much time to the study of explosives, with the result that in 1893 his new compound was adopted by the Japanese Navy, which gave it the name Shimosé powder. In 1899 the Shimosé Powder Factory was established at Akabane, and he was placed in charge of it. His explosive was employed for the first time in actual fighting during the Russo-Japanese War, where it proved to be extraordinarily effective. For his services in this connection he was twice decorated by the Japanese Government. Mr. Shimosé became a member of the Royal Society of Arts in 1906.

ALBERT CHANCELLOR, J.P.—The death occurred on the 9th inst. of Mr. Albert Chancellor, at the age of sixty-nine. Mr. Chancellor, who was until recently an auctioneer at Richmond, Surrey, was mayor of the borough in 1897 and again in 1902. He was also a Justice of the Peace, and formerly a member of the Surrey County Council. He was at one time Master of the Coachmakers' Company and President of Christ's Hospital Club. Mr. Chancellor became a member of the Royal Society of Arts in 1888, and in 1902 he read before it a paper on "The Origin and History of Carriages."

GENERAL NOTES.

SOYA-BEAN CULTURE IN CEYLON.—The soya bean which has come into prominence recently, owing to its commercial value, has now been successfully experimented with in Ceylon. The Agricultural Society secured a large quantity of seed some time ago from the Far East, and experiments were carried out at the Botanic Gardens at Peradeniya, but the cultivation proved a failure. The secretary of the Ceylon Agricultural Society has now succeeded, however, in turning out a large crop in the Government stock gardens in Colombo, producing two varieties, the Japan (white seed) and the Java (black seed), and seed will, it is said, be shortly available for distribution. It is expected that the cultivation of the soya bean will be taken up largely in Ceylon, for besides its value as an article of food it can be exported to the European and American markets.

MOTOR-BOATS IN ICELAND.—The value of motor power is becoming fully recognised by the fishermen of Iceland, judging from a recent report of the French Consul at Reykjavick. From this it appears that the old-time fishing boat propelled by oars is rapidly being superseded by the motor. The total number of motor-driven fishing boats along the coast of the island is now 410. They are chiefly small craft, of from four to five tons, and are more numerous in the north and north-east part, especially in the districts of Isafjord and Akuzegri. In the Westmann islands alone there are upwards of fifty of these little vessels. They are manned by about 1,000 persons. The Icelanders are setting a

Hosted by Google

good example by the interest they are taking in the marine motor, and it will not be long before the oar becomes a thing of the past.

INTERNATIONAL SOCIETY FOR THE PROMOTION OF COMMERCIAL EDUCATION.—The *Journal* of August 18th contained a report of the London meeting of the International Society for the Promotion of Commercial Education, which extended from July 24th to August 12th. From this it was evident that, regarded from the educational point of view, the meeting was remarkably successful. The audited accounts have now been published, and it is pleasant to learn that the financial success of the meeting has also been assured, as the committee are left with a small but satisfactory balance in hand. One of the most gratifying results of the London meeting is a considerable increase in the English list of membership, though the Society still possesses more members in many Continental countries than here. Among the new British life members are Lord Rothschild, Lord Joicey, Sir Edgar Speyer, the Right Hon. Frederick Huth Jackson, the Clothworkers' Company, and the Mercers' Company. The Society will hold its next meeting and course of lectures at Antwerp in the summer of 1912. The Belgian Government makes a large annual grant to the Society's funds, and will give material help in the organisation of the Antwerp course.

OIL FROM GRAPE SEED.—An oil of somewhat similar type to that of the olive may be obtained from the stones or seeds of the grape. During the eighteenth century the manufacture of this oil was an industry of considerable importance in many towns in France, especially at Albi (Department of Tarn). The seeds contain from 15 to 20 per cent. of oil, the manufacture of which, thanks to modern processes, has been revived in Italy during the last two or three years. Grape-seed oil is coming into use for soap making, as well as for lubricating and lighting purposes. It is estimated that from two to three million of quintals of this seed could be supplied annually by France alone, which, if separated from the skins of the grapes, would produce from 300,000 to 450,000 quintals (say 6½ to 10 million gallons) of oil. The value of the residuum after wine-making would be considerably enhanced as a raw material for distillation. The brandy (*eau de vie*) thus obtained would not only be of superior quality, but also free from any disagreeable taste due to the essential oil of the seed.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, NOVEMBER 20...Bibliographical, 20, Hanover-square, W., 5 p.m. Mr. G. K. Fortescue, "The British Museum Subject-Index."

Geographical, Burlington-gardens, W., 8.30 p.m. Dr. Tempest Anderson, "Volcanic Craters and Explosions."

British Architects, 9, Conduit-street, W., 8 p.m. Mr. H. H. Statham, "Modern French Sculpture."

London Institution, Finsbury-circus, E.C., 5 p.m. Mr. H. Beaumont, "Troyes."

TUESDAY, NOVEMBER 21...Civil Engineers, 25, Great George-street, S.W., 8 p.m. 1. Discussion on Mr. A. H. Roberts' paper, "The Loch Leven Water-Power Works." 2. Discussion on Mr. F. B. Sonnenschein's paper, "The Hydro-Electric Plant in the British Aluminium Company's Factory at Kinlochleven."

Statistical, at the ROYAL SOCIETY OF ARTS, John-st., Adelphi, W.C., 5 p.m. Mr. R. H. Hooker, "The Course of Prices at Home and Abroad, 1890-1910."

Photographic, 35, Russell-square, W.C., 8 p.m. Mr. W. B. Ferguson, "A New Density Meter."

Zoological, Regent's Park, N.W., 8.30 p.m. 1. Dr. G. Smith, "The Freshwater Crayfishes of Australia." 2. Mr. F. E. Beddard, "Contributions to the Anatomy and Systematic Arrangement of the Cestoidea. III.—On a New Genus of Tapeworms from the Bustard (*Eupodotis kori*)." 3. Mr. A. E. Cameron, "Structure of the Alimentary Canal of the Stick Insect (*Bacillus rossii* Fabr.), with a Note on the Parthenogenesis of this Species." 4. Mr. G. A. Boulenger, "Some Remarks on the Habits of British Frogs and Toads, with reference to Mr. Cummings's recent communication on 'Distant Orientation in Amphibia.'" 5. Mr. H. B. Preston, "Diagnoses of New Species of Terrestrial and Fluviatile Shells from British and German East Africa." 6. Mr. R. Lydekker, "On the Milk-Dentition of the Ratel."

Horticultural, Vincent-square, Westminster, S.W., 3 p.m. Mr. E. White, "The 1912 International Horticultural Exhibition."

WEDNESDAY, NOVEMBER 22...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Dr. J. Douglas, "The Industrial Progress of the United States of America."

Geological, Burlington House, W., 8 p.m.

THURSDAY, NOVEMBER 23...Cyclists' Touring Club, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. R. D. Maddock, "A Cycle Tour in Tyrol and the Dolomite Country."

Anthropological Institute, in the C.S.C. Theatre, Burlington-gardens, W., 8.30 p.m. (Huxley Memorial Lecture.) Professor F. von Luschan, "The Early Inhabitants of Western Asia."

Royal, Burlington House, W., 4.30 p.m.

Antiquaries, Burlington House, W., 8.30 p.m.

Child Study, 90, Buckingham Palace-road, S.W., 7.30 p.m. Mr. T. G. Tibbey, "Psychology of Reading."

Economics, London School of, Clare Market, W.C., 6 p.m. Dr. M. R. James, "Mediæval Libraries and their Manuscripts."

London Institution, Finsbury-circus, E.C., 6 p.m. Mr. A. E. Carey, "Breakwater Building."

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Mr. H. St. George Gray, "Excavations at the Great Stone Circle of Avebury, N. Wilts."

Electrical Engineers, Victoria-embankment, W.C., 8 p.m. Mr. R. Rankin, "Automatic Reversible Battery Boosters."

Mining and Metallurgy, Institution of, Burlington House, Piccadilly, W., 8 p.m. Dr. James Douglas, "The Development of the Copper Queen and the Warren Mining District."

Chemical, Burlington House, Piccadilly, W., 8.30 p.m. Berthelot Memorial Lecture by Prof. H. B. Dixon.

Literature, Royal Society of, 20, Hanover-square, W., 2.45 p.m. (The Academic Committee.) Obituary addresses. 1. Dr. G. W. Prothero, on "Sir Alfred Comyn Lyall." 2. Dr. W. J. Courthope, on "Edward Henry Pember."

FRIDAY, NOVEMBER 24...Engineers and Shipbuilders, North-East Coast Institute of, Newcastle-on-Tyne, 7.30 p.m.

Physical, Imperial College of Science, South Kensington, S.W., 5 p.m.

SATURDAY, NOVEMBER 25...Engineers and Shipbuilders, North-East Coast Institute of, Newcastle-on-Tyne, 7.30 p.m. (Graduates' Section.) Mr. W. Ayre, "Some Notes on the Strength of Ships."

Hosted by Google

Journal of the Royal Society of Arts.

No. 3,079. VOL. LX.

FRIDAY, NOVEMBER 24, 1911.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, NOVEMBER 27th, 8 p.m. (Cantor Lecture.) Professor VIVIAN B. LEWES, "The Carbonisation of Coal." (Lecture I.)

WEDNESDAY, NOVEMBER 29th, 8 p.m. (Ordinary Meeting.) A. E. BERRIMAN, "The Efficiency of the Aeroplane." DUGALD CLERK, F.R.S., will preside.

Further details of the Society's meetings will be found at the end of this number.

PROCEEDINGS OF THE SOCIETY.

SECOND ORDINARY MEETING.

Wednesday, November 22nd, 1911; The Right Hon. SIR HENRY MORTIMER DURAND, G.C.M.G., K.C.S.I., K.C.I.E., late H.B.M. Ambassador at Washington, in the chair.

The following candidates were proposed for election as members of the Society:—

Bates, Sir Percy Elly, Bart., Hinderton Hall, Neston, Cheshire.

Johnston, Francis Alexander, 16, Draycott-place, Chelsea, S.W.

Price, Herbert, J.P., Berry-street, Queenstown, Cape Colony, South Africa.

Roy, Charles S., Ph.D., 35, Mary-road, Stechford, Birmingham.

Singleton, Miss Esther, 854, Seventh-avenue, New York City, U.S.A.

Thomas, Cecil, 1, Great Pulteney-street, W.

Walton, Robert, 14, Rue Dieu, Paris, France.

The CHAIRMAN, in introducing the lecturer, said probably all present had heard of Mr. James Douglas and of the munificent donation of £20,000 which he had just made to the McGill University of Montreal.

The paper read was—

THE INDUSTRIAL PROGRESS OF THE UNITED STATES OF AMERICA.

By JAMES DOUGLAS, LL.D.,
Past President of the American Institute of Mining Engineers.

The industrial progress of the United States of America during the half century just past is interesting, not only by reason of the rapid development of the country, but of the forces which have been most active in stimulating it. It really dates from the termination of the Civil War. However baneful the passion which war excites, and deplorable the suffering and loss which it involves, it seems always to precede, and probably is efficient in producing, a period of great national activity, in which the rapid advances in the arts of peace obliterate the ravages of war, and smooth the rancorous feelings it excited. The terrible Civil War, which prostrated the South and strained the resources of the North from 1861 to 1865, certainly had that effect. It not only by force welded the nation into one, but it aroused a spirit of industrial energy, spurred on by generous motives.

Until, and even after, the Civil War was fought out, California and Oregon were isolated, by thousands of miles of almost uninhabited country, from the seat of government and the older States. But a railroad, commenced while the war was raging and finished in 1872, or seven years after the war closed, brought the East and the West into intimate touch, and gave the people some faint conception of the incalculable value of the vast intervening stretches of prairie and mountain and plateau, lying between the Missouri River and the Pacific. Laws were therefore framed with the view of utilising as rapidly as possible these boundless resources. When the vastness of the space to be peopled, and the wealth to be garnered from the soil and from the rocks of

Hosted by Google

half a continent, untouched by the hand of man, came to be even dimly realised by the united people, an invitation was given to the whole world, including even the Chinese, bidding all to enter and to help in harvesting the treasures which seemed so boundless. It was a policy instigated, not solely by motives of gain, but by a spirit of generosity and fraternity. These altruistic impulses are stronger in an early stage of a people's organic life than after industrial selfishness and class prejudice have chilled the enthusiasm, still warm, in the new-born nationality. While it is true that the most liberal land laws would not have succeeded in creating a great industrial nation in half a century had the resources to work upon not been present, it is equally true that without the laws and the democratic constitution the resources would have been more slowly developed.

Emigrants from Europe accepted eagerly the hearty invitation to people the West, but the opening of the West diverted the current of the native American population inland, towards the development of its own continental resources. One result has been that, with the accumulation of wealth and the growing sense of power, national ambition has expanded. The absorption of colonial possessions was inevitable. And it must follow that this great country, with its expanding commerce, will intervene, as a world power, in the world's politics. Nations, as they grow, resistlessly break away from restrictions which were wisely recommended and observed at an earlier stage of their development.

Another result of the discovery of the Great West has been that, in diverting American energy inland, it has transferred it from the sea. This influence was probably more effectual, though less conspicuously recognised, in its effect on American commerce, than the destruction of the old mercantile fleet by the "Alabama." The restless human elements of the Atlantic coast had previously gone to sea; but after the discovery of gold in California, and the extension of the railroad westward, the fertile prairie and the Rocky Mountains offered a more attractive outlet for the lover of adventure than the sailor's life, and the West coupled the promises of gain with abundance of danger. Thus, when a sailor became a pioneer, he gratified his impulse to break loose from the rigid confines of family life, the narrow circle of his neighbourhood, and the restrictions, political and social, which he resented in his old home. This temper has always been strong in the English stock, and finds its expression in the constitution of such new States as Oklahoma and such British colonies as New Zealand, where old limitations are removed, to be generally replaced by others as stringent. New England, the nursery of the American mercantile navy, has been deserted by her children. They scattered west, not east—to the temporary detriment of the American marine and American foreign commerce. But it would be a mistake to regard this aberration from racial habits and instincts as otherwise than very temporary. It was, and is, a racial instinct that drives Americans and Canadians to the western wilds, and it is in obedience to a national instinct, dating back to the early colonial days, that the American abhors crowding. The original colonists of Virginia and Massachusetts felt the influence of the unlimited space of an unoccupied continent, and yielded willingly to the reaction against the territorial and social restrictions of the British Isles. They numbered but a few thousand, and yet the shores of Massachusetts Bay and Chesapeke Bay were too narrow for them. They scattered to the north, and south, and west, formed new communities, and won more land from the wilderness. As long as the French hemmed them in between the Alleghanies and the sea, the area of expansion was defined; but once the barrier was broken the race swept westward, and bought or squatted on the land. Individual land-ownership was a legacy from colonial days. Both of the two first groups of colonists who left England in the seventeenth century, those who went to Virginia and those who went to New England, were fellow-partners in a company with English shareholders, one of whose assets was the land they acquired on the American continent. A modified species of communism therefore existed, but only for a very short time. The desire for the private ownership of the land the settlers cultivated was irresistible to men who had lived under the manorial and leasehold systems of Great Britain; and this preference has coincided so accurately with the growth of national prosperity on this side of the Atlantic, that almost all land legislation has favoured actual ownership and small holdings. For a time after the Declaration of Independence the lands of the Western domain were disposed of in large blocks to defray the war debt; but since then legislation has avowedly aimed at frustrating land monopoly and vesting its ownership in the actual cultivator. It has not always succeeded.

The same tendency has controlled the legis-

Hosted by Google

lation for the sale of the mineral and forest lands; but in every case a spirit of unbounded liberality in disposing of the public domain has characterised the laws. They were framed to encourage the development of the nation's resources at a time when the vast extent of these resources was not even dreamed of. They have succeeded in effecting the result aimed at to a degree which the law-makers could not possibly have anticipated. Though there can be no doubt that the marvellous development of the country is due to these liberal laws, the present agitation in favour of the reform, in the hope of the conservation of the national resources (though the two reforms are only incidentally related), expresses the general belief that they should have been reconsidered and revised. For while the laws have secured the unfolding and recovery of the national wealth, it is claimed that some of them have been abused so as to encourage the creation of monopolistic trusts. But, in fact, the recent Federal land laws have had very little influence on the materials out of which were created the great Trusts, that of late have attracted so much attention and comment. The iron ores of the Steel Trust in Michigan and Tennessee followed the land, and sugar and tobacco are not primarily Western products. What, however, must be borne in mind, in explanation of the remarkable growth of the country, is that the laws enacted since the war came into operation when the railroad system of the country was being rapidly built up, the steam engine was being improved, and when the means of generating and controlling the electric current were being studied, and when inventors were already conceiving the many industrial uses to which it has since been turned. The country, therefore, sprang into existence, industrially, at the very time these new forces were being brought into the service of man. And no people on the face of the earth were as eager and able to use them as the Americans. From colonial days labour has been scarce and costly; and, therefore, to devise machinery which will replace muscular exertion has become almost a natural and national faculty.

The Disposal of the Western Domain.

At the time of the Declaration of Independence only six of the thirteen States had definite boundaries. They were New Hampshire, Rhode Island, New Jersey, Pennsylvania, Delaware, and Massachusetts. Each of the others laid claim to ill-defined areas of the vast unexplored region west of the Appalachian Mountains. The ownership of these western lands by certain States was opposed by those States which did not share in their possession, mainly on the ground that "the resources of that general government, to which all contributed, should not be taxed for the protection and development of this region, while its advantages would inure to the benefit of the favoured few" ("A Century of Population," p. 19). In 1779, before the war was actually finished, Congress recommended Virginia and the other States to forbear settling or selling their unappropriated lands. All were turned over to the Federal Government except the Connecticut Reservation on Lake Erie, the ownership of which was disposed of by the State of Connecticut, before the jurisdiction over the same was relinquished to the Federal Government in 1800.

The North-west Territory—a still larger domain, some 900 miles by 700 miles—was constituted in 1787 as a single district and subsequently subdivided into five States, designated by number. Even so far-sighted a man as Thomas Jefferson, though under the inspiration of world-building, predicted that "the Western country was so vast and the facilities for transportation and communication so meagre, that it would be a thousand years before the country as far west as the Mississippi would be thickly settled." Facts have contradicted Jefferson's calculations, for the people have succeeded, by liberal legislation, in reducing from ten to one the number of centuries which have expired in filling, though not overcrowding, this vast expanse with an industrious population.

Lands Owned by the Federal Government.

On the creation of the Republic the colonies which became the Thirteen Federated States retained possession of their public lands within their recognised boundaries. But the United States — the Federal Government — retained control of most of its public lands under the constitutions granted by Congress to the States since created by it, and own virtually all the public land in the district of Alaska.*

The present total area of the United States, exclusive of Alaska, is 1,937,144,900 acres (that of Alaska is 378,165,700), but the public lands which passed to the Federal Government originally, and have been since obtained, were 1,441,436,160 acres. The unceded lands in 1904 were 473,836,402 acres; since that date about

* The country's gross area in 1790 was 820,377 square miles; the settled portion 239,935 square miles, or about 29 per cent. ("A Century of Population," a Census Document, p. 17).

Hosted by Google

20,000,000 acres have been disposed of, leaving about 450,000,000 acres in the public domain.* Of this the largest quantity is in the arid region, not over 10 per cent. of which can probably be irrigated; but a very much larger proportion is applicable to grazing.

Public lands have been disposed of under the following Acts of Congress passed since the Civil War, and in the following quantities, up to 1909 (Report of the Commissioner of the General Land Office):—

	Acres.
Under the Homestead Act since 1867	115,124,295
Under the Timber and Stone Act since 1878	31,400,133
Under the Desert Land Act since 1877	10,175,006
Under the Timber Culture Act since 1873	5,511,018
Under the Coal Lands Act since 1875	7,675,902
Under State Grants	37,886,678
Under Wagonroad and Railroad Grants	116,875,418
Under State Desert Land Segregations	2,657,489
Under Public and Indian Lands	19,892,503
Unappropriated (disposed of prior to above Acts)	731,354,081
	1,078,552,523

	Acres.
Total area	1,441,436,160
Total disposed of to 1909	1,078,552,523
Undisposed public land	362,883,637

as against 473,826,402 acres unsold in 1904.

A brief summary of some of these laws will explain in part the ease with which wealth has been accumulated, and the rapid strides which industrial progress has made in the United States.

Land Legislation Prior to the Homestead Act of 1862.

The first Homestead Act was passed in 1862, but previous to that date land legislation had occupied much of the attention of Congress. Perhaps the most important measure was the Ordinance of 1787, which guaranteed the absolute ownership of land. But the transfer of its vast domain by the Federal Government to the absolute owners has undergone many changes in both principle and practice.

The United States promised what they did not actually own when, in 1776,† they offered lands in "the western settlements" to deserters from the British ranks, and as a bounty to induce men to enlist in the continental army. But the Federal Government ultimately became owners of these tracts of land west of the Alleghanies, of which certain of the States had become possessors after the expulsion of the French and before the Revolution, and of the still larger north-western domain; with which, according to the Hon. John Jay,* "it may always be remembered to England's credit in the peace negotiations, Shelburne, declining all temptation to a contrary course, endowed the Republic." Mr. Jay describes this as its "gigantic boundaries at the south, west and north, which determined its coming power and influence." When in possession, the Federal Government fulfilled its pledge by rewarding its soldiers by grants of land. It also devoted a liberal portion to education, and sold the balance at $1 an acre in large lots to land companies and individuals, the minimum being an entire section of 640 acres. Land companies were formed to buy tracts by the millions of acres; for the sale of these apparently boundless spaces was regarded as, and really was, the readiest way of relieving the financial stringencies of the Government. Hamilton, as a financier, favoured giving, to the purchaser of one whole township of ten miles square or more, two years' credit, but he also saw the advantage of selling to settlers in small lots. The price of land was soon raised to $2 an acre. And early in the nineteenth century opposition to the disposal of the public domain in large blocks became so strong that the sections that might be sold to a single entryman became smaller and smaller, till in 1820 the present minimum of forty acres (a quarter-quarter section) was reached, and the payment might be made in four instalments. Meanwhile the General Land Office was organised on very much the lines it still possesses. The land debates alternated with settlers' relief debates during the early years of the last century, and stability of legislation was not reached till the Pre-emption Act of 1841 was passed. This was, however, only one of several statutes. The pre-emptor paid the established price, but he bought his acres at private sale, and the Government forfeited the advantage of putting the public domain up in large parcels at public auction. The present pre-emption law permits any authorised purchaser, who does not already own 320 acres, to buy 160 acres, on

* The Report of the Public Land Commissioner (p. xiii.), after giving the figure of 473,836,402 acres unsold in 1904, adds: "The latter figure of nearly a half a billion acres, while but a third of the original area, is still enormous."

which he must reside, and for which he must pay by certain deferred payments. It was the forerunner of the still more liberal system of homesteading, or the free grant of land to actual settlers, which was advocated as early as 1833, and was the object of the "Free Soilers" agitation. (Sato, p. 164.)

The Homestead Act.

The following summary of the homestead law and the method of acquiring land under it is given by Judge Lindley* :—

"The homestead laws secure to the head of a family, of lawful age, who is a citizen of the United States, or who has declared his intention to become such, the right to settle upon, enter, and acquire title to not exceeding one hundred and sixty acres of unappropriated non-mineral public lands, by establishing and maintaining residence thereon, and improving and cultivating the land for the continuous period of five years.

"To obtain an inceptive right to a homestead, the applicant files with the register of the local land office an application, stating his qualifications, and describing the land he desires to enter. If it appears from the tract-books that the land is of the character subject to entry under the law, and is clear—that is, unappropriated—the applicant is permitted to make entry of the land; the receiver of the land office issues a receipt for the fees paid for filing the application, a record is made in the local office, and the fact reported to the general land office. If the lands are returned as mineral, and borne on the tract-books as such, the homestead claimant will not be permitted to initiate his right until a hearing is had for the purpose of determining the character of the land. To use the common expression, the mineral must be 'proved off,' before any right to the land can be inaugurated under the agricultural land laws. Whatever may be the effect of the Surveyor-General's return, as evidence in litigated cases involving the character of the land, the land officers in administering the land laws accept such return as controlling their action in the first instance.

"It would seem that the estate acquired by a homestead claimant who has filed his application and received his preliminary receipt from the receiver of the land office, is of greater dignity than that acquired by filing a declaratory statement under the pre-emption laws. By the preemption laws the United States did not enter into any contract with the settler, or incur any obligation that the land occupied by him should ever be offered for sale. They simply declared that, in case their lands were thrown open for sale, the privilege to purchase should be first given to parties who had settled upon and improved them.

* "A Treatise on the American Laws Relating to Mines and Mineral Lands," Vol. I. pp. 204, 205.

"Public land covered by a pre-emption filing as to which there has been no payment made or final certificate issued, may be appropriated by Congress to public purposes, or otherwise disposed of, without infringing any legal right held by the pre-emptioner.

"In an opinion of Attorney-General McVeagh, given at the request of the Secretary of War, it was stated, that upon the 'entry' by the homestead claimant at the local land office, a right in his favour would seem to attach to the land, which is liable to be defeated only by failure on his part to comply with the requirements of the homestead law in regard to settlement and cultivation; that this right amounts to an equitable interest in the land, subject to the future performance by the settler of certain conditions, and, until forfeited by failure to perform the conditions, it must prevail, not only against individuals, but against the Government; that, in contemplation of the homestead law, the settler acquires an immediate interest in the land, which, for the time being at least, becomes severed from the public domain.

"The land department has invariably acted upon this theory; and the Supreme Court of the United States has given its sanction to the rule that such an entry, so long as it remains subsisting, is such an appropriation of the tract as segregates it from the public domain. Innumerable filings under the pre-emption laws have been accepted for the same tract by the land office; but from the moment a homestead entry is accepted and the preliminary receipt issued, no further applications or filings for the tract are permitted, so long as the entry remains uncancelled.

"Although the land may be, in fact, mineral in character, and a mining claim be located thereon, no application to patent such mining claim will be received by the land officers until a hearing is had to determine the character of the land.

"If the land be found at such hearing to be mineral in character, a cancellation *pro tanto* of the homestead entry will be ordered, and the mineral lands will be segregated, whereupon the mineral applicant may proceed to patent."

Under the Homestead Act there have been 850,728 entries of quarter sections of 160 acres, covering 115,124,295 acres. The size of the entries was therefore about 10 per cent. less than the law allowed. The object of the Act was to settle the land with actual agriculturists, and to discourage its acquisition in large blocks by individuals or corporations. A man, once the patent is issued, can do what he will with his own and dispose of it to corporation promoters, but the patent is only issued to citizens who have nominally lived on the land for five years, or aliens who have declared their intention of becoming citizens. And the same citizen can make only one entry on any class of the public lands.

Hosted by Google

Instead of a residence of five years on the land an Act was passed (Sec. 2301 of Revised Statutes, July 1st, 1881), by which, on payment of $2.50 per acre, a patent is issued to the applicant after only fourteen months' residence. Over twenty millions of acres have been purchased under these conditions; but as the Act has been used to facilitate the concentration of land into large holdings, the Commission of 1904 recommended the repeal for the following reason:—

"The object of the homestead law was primarily to give to each citizen, the head of a family, an amount of land up to 160 acres, agricultural in character, so that homes would be created in the wilderness. The commutation clause, added at a later date, was undoubtedly intended to assist the honest settler, but, like many other well-intended acts, its original intent has been gradually perverted, until now it is apparent that a great part of commuted homesteads remain uninhabited. In other words, under the commutation clause the number of patents furnished no index to the number of new homes."

Despite the manifest intention, therefore, of the laws to create small holdings, and the precautions taken to prevent their perversion, the tendency to create large estates has not been altogether prevented. But the result of the policy has, on the whole, attracted to the land small industrious farmers, who have paid off their debts, become independent, and constitute one of the most stable elements of the population. Nevertheless the Commission of 1904 concludes its report with the following sinister reflection*:—

"Detailed study of the practical operation of the present land laws, particularly of the Desert Land Act and the commutation clause of the Homestead Act, shows that their tendency far too often is to bring about land monopoly rather than to multiply small holdings by actual settlers. The land laws, decisions, and practices, have become so complicated that the settler is at a marked disadvantage in comparison with the shrewd business man who aims to acquire large properties. Not infrequently their effect is to put a premium on perjury and dishonest methods in the acquisition of land. It is apparent, in consequence, that in very many localities, and perhaps in general, a larger proportion of the public land is passing into the hands of speculators and corporations than into those of actual settlers who are making homes.

"This is not due to the character of the land. In all parts of the United States known to your Commission, where such large holdings are being acquired, the genuine homesteader is prospering alongside of them under precisely the same conditions. Wherever the laws have been so enforced as to give the settler a reasonable chance he has settled, prospered, built up the country, and brought about more complete development and larger prosperity than where land monopoly flourishes. Nearly everywhere the large landowner has succeeded in monopolising the best tracts, whether of timber or agricultural land. There has been some outcry against this condition. Yet the lack of greater protest is significant. It is to be explained by the energy, shrewdness, and influence of the men to whom the continuation of the present condition is desirable.

"Your Commission has had inquiries made as to how a number of estates, selected haphazard, have been acquired. Almost without exception collusion or evasion of the letter and spirit of the land laws was involved. It is not necessarily to be inferred that the present owners of these estates were dishonest, but the fact remains that their holdings were acquired or consolidated by practices which cannot be defended.

"The disastrous effect of this system upon the well-being of the nation as a whole requires little comment. Under the present conditions, speaking broadly, the large estate usually remains in a low condition of cultivation, whereas under actual settlement by individual home-makers the same land would have supported many families in comfort and would have yielded far greater returns Agriculture is a pursuit of which it may be asserted absolutely that it rarely reaches its best development under any concentrated form of ownership.

"There exists, and is spreading in the West, a tenant or hired labour system which not only represents a relatively low industrial development, but whose further extension carries with it a most serious threat. Politically, socially, and economically this system is indefensible. Had the land laws been effective and effectually enforced its growth would have been impossible.

"It is often asserted in defence of large holdings that, through the operation of enlightened selfishness, the land so held will eventually be put to its best use. Whatever theoretical considerations may support this statement, in practice it is almost universally untrue. Hired labour on the farm cannot compete with the man who owns and works his land, and if it could the owners of large tracts rarely have the capital to develop them effectively.

"Although there is a tendency to subdivide large holdings in the long run, yet the desire for such holdings is so strong, and the belief in their rapid increase in value so controlling and so widespread, that the speculative motive governs, and men go to extremes before they will subdivide lands which they themselves are not able to utilise.

"The fundamental fact that characterises the present situation is this: That the number of patents issued is increasing out of all proportion to the number of new homes."

* Report of the Public Lands Commission, 1904, p. xxiii.

It is beyond my purpose to refer to Canadian subjects, but I cannot refrain from making an extract from the report of the Public Lands Commission already referred to (p. 79), reflecting favourably on Canadian land laws:—

"If it were intended by your instructions of July 25th, 1904, to have this Committee recommend or suggest changes in the Free Homestead Act in its judgment necessary to obtain in a greater measure the objects sought for by Congress, your Committee would first refer to certain features contained in the Homestead Act enacted by the national legislative branch of the Canadian Government. Ample opportunity has been given your agent having in charge the commutation clause of the Homestead Act to watch the workings of the Canadian law, and make comparisons between it and our own free homestead law. No better example of this can be found than along the Rainy River, which forms the boundary line between the State of Minnesota and the Province of Ontario, extending over a stretch of territory nearly 100 miles in length. Along the southern bank of this river hundreds of entries have been made under our Free Homestead Act, the Timber and Stone Act, and the commutation clause of the Homestead Act, and the result has been that, with the exception of some half-dozen well-conducted farms, the territory is uninhabited, and presents a general appearance of virgin forest, stretching from the eastern end of Rainy Lake to the Lake of the Woods on the west.

"On the Canadian side of this river the timber has been disposed of on a stumpage basis and the land thrown open to settlement under the Canadian homestead law, requiring as it does specific acts by the entrymen as to residence and cultivation, and prescribed periods and acreage each year during the life of said entries. The result of this system has been that to-day the entire northern shore of the Rainy River is inhabited, and the territory under a high state of cultivation. Fine farms are everywhere to be found, while on the American side just the reverse is true. On the Canadian side roads have been built and school districts established, while on the American side few internal improvements are to be found. The soil is identical and natural conditions are the same, so no other theory can be advanced for the present condition of things than that the Canadian system is more conducive to actual settlement and cultivation.

"Your Committee has endeavoured to confine itself to facts, and treat the subject from the impartial standpoint, and the evidence seems clear and convincing that the Act has resulted in fraud, speculation, destruction of forests, the placing of thousands of acres in the hands of a few persons or corporations, and the stultifying of honest and industrious settlement and improvement of the public domain. Almost every good, honest citizen, unbiased by personal interest or greed, was emphatic in denouncing the commutation clause of the Homestead Act and demanding its repeal. In some cases it was found that men who had formerly profited by its workings and retired from active usiness, were now demanding its repeal in terms which could not be misunderstood."

Railroad Land Grants.

More land was in the past given as a bonus to encourage railroad building than has been transferred to homesteaders. The earliest grants were made in 1850, and those prior to 1862 were made to States as trustees and agent of transfer for the railroads. Only three grants were made after 1870, and about 75 per cent. of the whole was in the encouragement of trans-continental roads. The lands ceded to encourage railroad building were in the territories adjacent to the assisted roads. The largest grants were of land contiguous to the early trans-continental roads—the Union and Kansas Pacific, the Central Pacific, the Northern Pacific, the Southern Pacific, and the Santa Fé. In all, seventy-nine land grants were made, covering nearly 200,000,000 acres, but, "by reason of forfeiture by Congress because of the failure of the grantees to construct the roads as required by the granting Act, this amount was reduced to such an extent that the acreage at this time is estimated at 155,000,000 acres."*

Most of the land, especially the lumber land, was unsaleable at the time, and was therefore merely a prospectively valuable asset. It, however, assisted the roads in raising funds, and it is charged that the roads, owing to the rising value of both agricultural and lumber lands, are not over-zealous in trying to dispose of their extensive unsold holdings. Mineral lands were not intentionally granted. And where such minerals, including oil, have been found, the right of the concessionaire to enjoy this advantage is being questioned by the administration.

Though the Government no longer makes grants of land to encourage the building of the large railroads, it still cedes the use of the right of way and a certain acreage for station grounds to any railroad traversing the public domain.

To encourage the building of the first trans-continental roads, Congress lent large sums to the companies, which have been returned. But the need of transportation was so urgently felt by the population of thinly settled districts, that exemption of taxes for limited periods, bonuses by municipalities and counties of station grounds and rights of way, and even grants of money, were made. But of late such encouragement has been seldom extended to railroad

* Report of the Public Lands Commission, 1904.

Hosted by Google

builders. In fact, the direction of public feeling has been generally hostile to the railroad companies.

Grants of Public Lands to Territories and States.

The Federal Government generally confers on newly-created Territories and States large tracts of land for specific purposes, retaining, however, the greater portion, including coal and mineral lands. The grants to States and Territories up to November, 1904, were:—

	Acres.
For common schools	69,058,443
For charitable, educational, penal, and reformatory institutions	8,539,464
For internal improvements	10,631,482
For public buildings	1,162,731
For salt springs and contiguous tracts	606,045
	89,998,165

Until thinly populated sections of the Republic had been endowed with the responsibilities and privileges of Statehood, they enjoyed a limited self-government, as Territories, under the supervision of Congress. But the land within the Territories was retained by the National Government, with the exception of such grants as may have been entrusted to the Territorial Government to be sold for special purposes. On the creation of States, Congress has not followed a uniform rule in its grants of public lands to the new self-governing communities, but has always endowed them most liberally with land for educational purposes. As early as 1785 an Ordinance was passed assigning 680 acres of land, or one thirty-sixth of the entire public domain, to every township "for the maintenance of public schools within said township." And every new State since the admission of, and including, Oregon, has received an additional grant of the thirty-sixth section. Land grants to new States for the maintenance of universities and agricultural colleges have been the rule. In all cases the Federal Government have aimed at excluding known mineral lands from the control of new States; but they have otherwise been amply provided with the means—if wisely disposed of—for educating their children in even more advanced studies than the elements.

Texas has been an exception; for, being an independent republic when incorporated into the Union, one of the conditions of Texan annexation was that she should "retain all the vacant and unappropriated lands lying within its limits, to be applied to paying the debts and liabilities of Texas, and the remainder of said lands, after discharging such debts and liabilities, to be disposed of as said State may direct; but in no event are such debts and liabilities to become a charge upon the Government of the United States." But Texas is liberal in the support of education. The Constitution of 1876 assures to the School Fund of Texas half the proceeds of the sale of public lands. (Report of the Public Lands Commission, p. 33.)

Indian and Military Reservations.

For Indian reservations, 70,448,126 acres have been appropriated, but this area can be cut down by Act of Congress or Executive order, when the reservation was assigned to a tribe by the action of the President.

The treatment of the Indians by the United States Government has been a subject of acute controversy, both at home and abroad. Large tracts of rich agricultural and grazing lands were allotted to them as reservations when their character and value were not known even by the administration. That it should remain a wilderness with cultivation all around was an intolerable condition. I have twice driven across the Sioux reservation from St. Pierre, on the Missouri, to Rapid in the Black Hills—across more than a hundred miles of the richest prairie in Dakota, without seeing a single Indian or an acre of cultivation. Some remedy for such anomalies had to be found.

As to the military reservations, most of them have been restored to the public domain, when abandoned, owing to the present system of army concentration. The expansion of the railroad system throughout the Rocky Mountains renders unnecessary a large number of isolated military posts.

National Parks.

Of late years large areas of the public domain which are remarkable for the possession of great natural beauty, like the Yellowstone Park in Montana, or the Yosemite in California, have been secured from desecration, or from private ownership, by conversion into national parks; and, to rescue prehistoric and historic monuments, the land on which they stand, if not owned by the Government, may be acquired by purchase, and set apart under the National Monument Act. These appropriations are evidences of a certain æsthetic and historical sense in the popular character, with which it is not generally credited.

Desert Land Act.

Under the Desert Land Act, 10,175,006 acres have been ceded to entrymen in blocks of a square mile, on condition that a certain portion

Hosted by Google

of each entry be adequately irrigated. In applying this, and the provisions of all other statutes, curious anomalies inevitably occur.

Land to be Irrigated under Reclamation Service.—Of the millions of acres still within the public domain a considerable portion is within the Arctic circle, rich, doubtless, in mineral, but of little value for forestry or agriculture. Of the balance, by far the larger quantity is comprised within the Rocky Mountains, and therefore within not only the barren but the arid zone. Of this, 1,900,000 acres are already under process of being irrigated by the Reclamation Service. Some of the projects aim at storing flood waters by damming mountain torrents; others attain the same object by raising the level of lakes, and still others will draw water, loaded with fertilising material from such comparatively large and sluggish rivers as the Colorado and the Rio Grande. This work is being done at the expense of the Federal Government, and by the Reclamation Service, under the direction of the United States Geological Survey.

"The total sum set aside for all classes of projects is $34,270,000, and the amount of land to be irrigated is 1,909,000 acres. The average value of irrigated land in the United States is $47 per acre. This acreage will, therefore, add $89,723,000 to the taxable property of the United States in land values alone. According to the census report of 1900, the average annual income from irrigated land is $15 per acre. On this basis an income of $28,735,000 per annum will be added to the nation's wealth."

The figures are, of course, departmental calculations.

While the policy of the Government is to withdraw from corporate control in the future the forests and the waters of the public domain, whether available for power generation or irrigation, small holdings in the arid region will be irrigated by pumping, when underground flow is near the surface, and by catching the rainfall in artificial reservoirs. Such irrigation projects are carried out by corporations, associations of ranchers, or by individuals, and will undoubtedly render fertile a large acreage of desert land in small separate areas.

Timber and Stone Acts.

Three and a half million acres of timber land have been sold in California, Oregon, Nevada, and Washington, at $2.50 per acre under the Timber and Stone Act (Public Timber Laws, p. 98). The entrymen can take up only 160 acres; but this provision has not prevented the forest lands passing into the possession of large proprietors, either through purchase from entrymen or by the use of lieu land scrip—that is, scrip which has been issued as a reward for military and other service, and as a bonus to the railroads. Some such scrips are or have been transferable, and good, therefore, for the purchase from Government of certain classes of land. To avoid the destruction of the forests through wasteful methods of lumbering, forest fires, and other preventable causes, the President has used the authority conferred on him by the Act of March 3rd, 1891, to withdraw from the public domain and create as forest reserves "public lands wholly or in part covered with timber or undergrowth." Lumbering may, however, be conducted under licence on these reservations, and agricultural lands upon the same may be disposed of. The acreage now included in the 150 national forests is 194,505,325 acres. (Report of the Commissioner of General Land Office for 1909, p. 31.)

Mineral Land Laws.

While the homestead laws continue to meet with popular approval, it is very generally recognised that the laws under which desert land, and those under which coal, mineral, timber and stone lands can be secured, should be radically amended. These laws were all passed with the object of stimulating mining, quarrying, and of encouraging the reclamation of the country's desert districts. Some of the measures erred in the direction of over-liberality, while others were framed to put, as it was hoped, the minerals as well as the land into the possession of the poor man, and prevent their being monopolised by wealthy corporations. But in every case the policy was to develop the natural resources as speedily as possible and induce population to enter. The policy has succeeded so far beyond anticipation that if the legislators of a generation ago had been able to foresee the rapidity with which wealth would grow, and the national resources be proportionately used up, they might have hesitated to frame measures as generous as those which have attracted to the country the most enterprising spirits of all Europe, and to have afforded to men of magnificent powers of imagination and organisation, aided by great wealth, the material for creating huge enterprises, which it is now found more difficult to control than it was to create.

In the colonies before the Revolution the title to the common minerals passed, under the common law rule, to the owner of the soil, and the colonies, when they entered the Federation, retained control of these lands. But the mineral lands owned by the United States after the Revolution were disposed of under three statutes.

Hosted by Google

1. An Ordinance (May, 1785), entitled "An Ordinance for ascertaining the mode of disposing of lands in the Western Territory," which was of the vaguest character.

2. The Lode Law of 1866.

3. The General Mining Law of 1872, known as the Law of the Apex.

There was substantially no mining done in the United States till the purchase of Louisiana and the acquisition of the lead mines of Missouri, which had been one of the most alluring baits of Law's Mississippi scheme. As a result of the Louisiana purchase, a law was passed in 1807 to the effect that "the President of the United States shall be and is hereby authorised to lease any lead mine which has been or may hereafter be discovered in the Indian Territory for a period not exceeding five years." The leasing of mineral lands was entrusted to the War Department, but it did not impose on it a heavy burden till 1845, when, after the extinction of the Michigan Indian titles in 1843, active mining commenced in the native copper deposits of Lake Superior. For two years only, subsequently to 1845, the system of leasing was carried out. It was the system inherited from the Mother country, but badly practised when applied on the large scale by inexperienced officials.

The Hon. Abraham S. Hewitt, in his interesting address to the American Institute of Mining Engineers on "A Century of Mining," tells of the process by which the leasing system was supplanted by the out-and-out purchase system* :—

"For a few years the rents were paid with tolerable regularity, but after 1834, in consequence of the immense number of illegal entries of mineral land at the Wisconsin land office, the smelters and miners refused to make any further payments, and the Government was entirely unable to collect them. After much trouble and expense, it was, in 1847, finally concluded that the only way was to sell the mineral land, and do away with all reserves of lead or any other metal, since they had only been a source of embarrassment to the department.

"Meanwhile, by a forced construction (afterwards declared invalid) of the same Act, hundreds of leases were granted to speculators in the Lake Superior copper region, which was from 1843 to 1846 the scene of wild and baseless excitement. The bubble burst during the latter year; the issue of permits and leases was suspended as illegal, and the Act of 1847, authorising the sale of the mineral lands and a geological survey of the district, laid the foundation of a more substantial property."

It may be doubted whether reform of the working of the leasing system, instead of its abolition, would not have been a wiser course; but the radical step of alienating absolutely the mineral lands was recommended by President Polk on December 2nd, 1845, and enacted into law, and the copper lands of Michigan were offered for sale at $5 an acre, the price at which mineral lands have ever since been disposed of.

The principal argument adduced by President Polk for the change of policy is the unprofitableness of leasing. He says:—

"According to the official records, the amount of rents received by the Government for the years 1841, 1842, 1843, and 1844, was $6,354.74, while the expenses of the system during the same period, including salaries of the superintendents, agents, clerks, and incidental expenses, were $26,111.11, the income being less than one-fourth of the expense. To this pecuniary loss may be added the injury sustained by the public in consequence of the destruction of timber, and the careless and wasteful manner of working the mines."

But President Fillmore, in his annual message to Congress on December 2nd, 1849, referring to the application of the land laws to the newly-acquired territory of California, gives as the most logical reason for the out-and-out sale of the public lands that "the relation of debtor and creditor between the citizens and the Government would be attended with many mischievous consequences." The public feeling in favour of actual ownership of land has always been strong.

The first mining excitement followed the first successful effort to mine the metallic copper of Lake Superior, and, as we have seen, the result was the adoption of the sale in preference to the lease system. The next modification of importance followed the rush for gold in California, then a remote section, newly acquired by conquest and subsequent treaty. To meet local exigencies, a mining code was framed by the miners, through methods curiously illustrative of the working of popular institutions.

When California was occupied by the United States the Mexican mining laws were in force, and till 1849 the conquered province remained under military rule. Colonel Mason, the governor, while still ignorant that the treaty of Guadaloupe Hidalgo had been signed on February 2nd, issued the following proclamation from Monteray on February 12th, 1848:—

"From and after this date the Mexican laws and customs now prevailing in California relative to the denouncement of mines are hereby abolished.

* *Transactions of the American Institute of Mining Engineers*, Vol. V. p. 181.

Hosted by Google

"The legality of the denouncements which have taken place, and the possession obtained under them since, till the occupation of the country by the United States forces, are questions which will be disposed of by the American Government after a definitive treaty of peace shall have been established between the two Republics."

Without questioning the right of Colonel Mason to revoke arbitrarily the existing mining law, the miners obeyed, and framed rules and regulations, not only for regulating the conduct of mining, but for the mode of acquiring the mines themselves, although all of them were virtually trespassers on the public domain.

Hence arose the custom, afterwards embodied in the United States statute, of allowing neighbouring miners to create a mining district and constitute themselves into a legislative body, whose rules and regulations, if not contrary to either Federal or State or Territorial laws, have a binding obligation. These self-constituted legislators in California followed the Mexican code so far as it applied to discovery and development, but they introduced into their mining code a principle which had no place in any modern mining statute. To them the ownership of the surface was subsidiary to that of the lode or quartz vein, which might happen to crop out at any given spot. Therefore they conceded to the owner of the outcrop the right to follow his discovery to any depth, and under the "dip, spur, and angle clause" of their amateur regulation, created extra-lateral rights and introduced the law of the Apex, which came to be the distinguishing feature of the statutes passed in 1866 and 1872, and which has remained unaltered till to-day. This anomalous law of the Apex was apparently copied from an old custom confined to the High Peak district of Derbyshire, and probably incorporated in the California mining code at the suggestion of some English miners. Judge Field, who was ultimately elevated to the Supreme Court of the United States, but who had been one of the pioneers of California —an *alcalde* before the admission of the State— a legislator in the first Assembly, and a State judge, thus graphically describes the process by which these mining regulations were framed by these early intelligent miners:—

"The discovery of gold in California was followed, as is well known, by an immense immigration into the State, which increased its population within three or four years from a few thousand to several hundred thousand. The lands in which the precious metals were found belonged to the United States, and were unsurveyed and not open by law to occupation and settlement. Little was known of them further than that they were situated in the Sierra Nevada mountains. Into these mountains the emigrants in vast numbers penetrated, occupying the ravines, gulches and canyons, and probing the earth in all directions for the precious metals. Wherever they went they carried with them that love of order and system and of fair dealing which are the prominent characteristics of our people. In every district which they occupied they framed certain rules for their government, by which the extent of ground they could severally hold for mining was designated, their possessory right to such ground secured and enforced, and contests between them either avoided or determined. These rules bore a marked similarity, varying in several districts only according to the extent and character of the mines; distinct provision being made for different kinds of mining, such as placer mining, quartz mining, and mining in drifts and tunnels. *They all recognised discovery*, followed by appropriation, as the foundation of the possessor's title, and development by working as the condition of its retention. And they were so framed as to secure to all comers within practicable limits absolute equality of right and privilege in working the mines. Nothing but such equality would have been tolerated by the miners, who were emphatically the law-makers, as respects mining upon the public lands in the State. The first appropriator was everywhere held to have, within certain well-defined limits, a better right than others to the claims taken up; and in all controversies, except as against the Government, he was regarded as the original owner, from whom title was to be traced . . . These regulations and customs were appealed to in controversies in the State courts, and received their sanction; and properties to the value of many millions rested upon them. For eighteen years, from 1848 to 1866, the regulations and customs of miners, as enforced and moulded by the courts and sanctioned by the legislation of the State, constituted the law governing property in mines and in water on the public mineral lands."

The Argonauts not only carried to the west coast the habits of self-government which were the heritage of the race, but carried them into practice with the same independence and originality as characterise most of the legislation of the colonists of Australia.

The rapid development of the Comstock Lode, after its discovery in 1859, rendered the framing of a Federal mining law a matter of necessity, and therefore in 1866 Congress enacted the first law under which a Federal title could be obtained to Federal mining land. The provisions of the Act are as vague as its title—"An Act granting the right of way to ditch and canal owners through the public lands, and for other purposes." Lindley says (I. p. 53):—

"The title gives no clue to the scope of the Act. As a matter of fact, the title belonged to another

Hosted by Google

Act which had passed the house, and for which the Mining Act was substituted in the Senate, without any attempt to change the title, and in this form passed both houses."

The Act provided:—

"1. That all the mineral lands of the public domain should be free and open to exploration and occupation;

"2. The rights which had been acquired in these lands under a system of local rules, with the apparent acquiescence and sanction of the Government, should be recognised and confirmed;

"3. That titles to at least certain classes of mineral deposits or lands containing them might be ultimately obtained."

The Act, however, which is still in force, is that passed in 1872 as "An Act to Promote the Development of the Mining Resources of the United States." The Act expresses decisively the liberality with which the country has disposed of its mineral lands, and the result has certainly justified its title and intent. The Preamble states:—

"Be it enacted by the Senate and House of Representatives of the United States of America, in Congress assembled. 1. That all valuable mineral deposits in land belonging to the United States, both surveyed and unsurveyed, are hereby declared to be free and open to exploration and purchase, and the lands in which they are found to occupation and purchase, by citizens of the United States, and those who have declared their intention to become such, under regulations prescribed by law, and according to the local customs or rules of miners, in the several mining districts so far as the same are applicable and not inconsistent with the laws of the United States."

The extent of the mining claim is prescribed as follows:—

"A mining claim located after the passage of this Act, whether located by one or more persons, may equal, but shall not exceed, one thousand five hundred feet in length along the vein or lode; but no location of a mining claim shall be made until the discovery of the vein or lode within the limits of the claim located. No claim shall extend more than three hundred feet on each side of the middle of the vein at the surface, nor shall any claim be limited, by any mining regulation, to less than twenty-five feet on each side of the middle of the vein at the surface, except where adverse rights existing at the passage of this Act shall render such limitation necessary. The end lines of each claim shall be parallel to each other."

The extralateral rights of the early California regulation are secured to the locator under the Federal law, under the third clause of the Act:—

"That the locators of all mining locations heretofore made . . . shall have the exclusive right of possession and enjoyment of all the surface included within the lines of their locations and of all veins, lodes or ledges, throughout their entire depth, the top or apex of which lies inside of such surface lines extended downward vertically, although such veins, lodes or ledges may so far depart from a perpendicular in their course downward as to extend outside the vertical side lines of the said surface locations; provided that their right of possession to such outside parts of said veins or ledges shall be confined to such portions thereof as lie between vertical planes drawn downward as aforesaid, through the end lines of their locations, so continued in their own direction that such planes will intersect such exterior parts of said veins or ledges. And provided further, that nothing in this section shall authorise the locator or possessor of a vein or lode which extends, in its downward course, beyond the vertical lines of his claim, to enter upon the surface of a claim owned or possessed by another."

Whether granting these extralateral rights has advanced the progress of mining is a disputed question, but they have been the source of most protracted and costly litigation.

The Act prescribes the manner in which a mining claim must be monumented and recorded, and the amount of work which must be actually done upon it, either above or below ground per annum ($100 = £20) in order to secure possessory rights. No rent or royalty is exacted by the Federal Government, but after $500 have been expended on the claim, the possessory title may be converted into an absolute patented title by payment of $5 per acre. The Act is admittedly defective in many of its provisions, but it would be foreign to my purpose to discuss its shortcomings. My object is to emphasise the motive which actuated the people, through their legislators, in throwing open all their lands, agricultural and mineral, not only to occupation, but to actual ownership by citizens or by anyone who has "declared his intention to become such." Under the Homestead Act the agricultural land is given freely; under the mining law no charge is made for the possessory title, and for a patent to a mining claim the trifling price of £1 per acre, hardly enough to meet the administration cost of the land department. Considering the incalculable hidden mineral wealth of the western half of the continent, it is not to be wondered at if the active spirits of the world accepted the cordial invitation to share it on such liberal terms, and that it has been uncovered, developed and marketed with such extraordinary speed, at extravagant profits to some, and that it has created spasms of speculative mania which have not had a healthy effect on public morals.

Hosted by Google

Mining companies are permitted the liberal allowance of 5,000 acres, but if a company reaches its limit, the same shareholders simply organise another. Metal mining, therefore, on a large scale can be carried on without evasion of any law.

Most of the coal and iron is mined east of the Missouri, and their possession passed to the owners of the land. But the gold and silver, and most of the copper and lead, are produced in the Rocky Mountains States under the liberal Federal laws which we have described. The sum total in value for 1908, as given by the United States Geological Survey, is as follows:—

Non-metallic products	$1,045,497,000
Metallic ,, . . .	549,923,000
Unclassified	250,000
	$1,595,670,000

The value of the metals in 1910 is given by the mineral industry as $791,702,857

Assuming the most modest estimate of actual profits on this large sum, we begin to appreciate the wealth that is accumulating in the country. Nor does this all fall to the lot of the shareholders of the large mining companies. If we take, for instance, the 2,000,000 acres of mineral lands which have been sold by the Federal Government, by far the largest proportion has been first located by prospectors and sold at often high figures. The poor man has been given the prospects, gratis, by the Federal Government, while the corporation has paid him the higher value of a promising, though perhaps undeveloped holding. Comparatively little actual mining is done by the poor man. He avoids doing more than will give presumptive value to his claim, and even if it proves to be a claim which may develop into a mine he obtains for it a high speculative value.

Coal Land Laws.

The Coal Land Laws, regulating the sale of coal lands, date from July 1st, 1864, and March 13th, 1865, but the Act under which most of the coal lands have been sold came into effect in 1873.

The coal land laws offer an interesting study of good intentions misapplied. The law-makers applied to coal lands the rules which were quite applicable to agricultural lands. They did not offer the coal for nothing, but they put a very small value on the land which covers it, and parted with land and coal together.

But the law limits the amount of coal land which can be taken under a single entry to 160 acres—the agricultural quarter section—and forbids more than two continuous entries to be consolidated into a working organisation. After the formalities have been fulfilled and the land paid for, as in the case of agricultural land, the entryman can do what he likes with his own property, but if he has made a contract, implied or expressed, to sell his coal, before he actually obtains his patent, he is subject to criminal action and the forfeiture of his property. The coal land entries, from the passage of the Act, March 3rd, 1873, to June 30th, 1909, were 3,558, covering 7,675,992 acres. (Report of the Public Lands Commission, 1909, p. 42.)

The coal land laws, under which all coal lands under control of the Federal Government have heretofore been disposed of, provide that—

"Every person above the age of twenty-one years, who is a citizen of the United States, or who has declared his intention to become such, or any association of persons severally qualified as above, shall, upon application to the register of the proper land office, have the right to enter, by legal subdivisions, any quantity of vacant coal lands of the United States not otherwise appropriated or reserved by competent authority, not exceeding one hundred and sixty acres to such individual person, or three hundred and twenty acres to such association, upon payment to the receiver of not less than ten dollars per acre for such lands, where the same shall be situated more than fifteen miles from any completed railroad, and not less than twenty dollars per acre for such lands as shall be within fifteen miles of such road."

The declaration which the entryman makes is as follows:—

"I, ______________, hereby apply, under the Provisions of 'the Revised Statutes of the United States,' relating to the sale of coal lands of the Township of ____________, of range ____________, in the district of lands subject to sale at the land office at ______________, and containing ____________ acres; and I solemnly swear that no portion of said tract is in the possession of any other party; that I am twenty-one years of age, a citizen of the United States (or have declared my intention to become a citizen of the United States), and have never held nor purchased lands under said Act, either as an individual or as member of an association; and I do further swear that I am well acquainted with the character of said described land, and with each and every legal subdivision thereof, having frequently passed over the same; that my knowledge of said land is such as to enable me to testify understandingly with regard thereto, that said land contains large deposits of coal, and is chiefly valuable therefor; that there is not, to my knowledge, within the limits thereof any vein or lode of quartz or other rock in place bearing gold, silver or copper, and that there is not within the limits of said land, to my knowledge, any valuable deposit of gold, silver or copper. So help me God."

Hosted by Google

The affidavit is so worded that it renders liable to prosecution for perjury every entryman who has even a remote intention of selling his claim, and not working it himself. But the law heretofore has been administered with reasonable latitude. Still it is manifestly inapplicable to the present industrial conditions.

President Roosevelt, in his Message to Congress on December 17th, said:—

"I am gravely concerned at the extremely unsatisfactory condition of the public land laws, and at the prevalence of fraud under their present provisions. For much of this fraud the present laws are chiefly responsible. There is but one way by which the fraudulent acquisition of these lands can be definitely stopped, and therefore I have directed the Secretary of the Interior to allow no patent to be issued to public lands under any law until by an examination on the ground actual compliance with that law has been found to exist. For this purpose an increase of special agents in the General Land Office is urgently required; unless it is given, *bona fide* would-be settlers will be put to grave inconvenience, or else the fraud will in large part go on.

"Further, the Secretary of the Interior should be enabled to employ enough mining experts to examine the validity of all mineral land claims, and to undertake the supervision and control of the use of the mineral fuels still belonging to the United States. The present coal law limiting the individual entry to 160 acres puts a premium on fraud by making it impossible to develop certain types of coal-fields and yet comply with the law. It is a scandal to maintain laws which sound well, but which make fraud the key without which great natural resources must remain closed. The law should give individuals and corporations, under proper Government regulation and control (the details of which I shall not at present discuss), the right to work bodies of coal land large enough for profitable development. My own belief is that there should be provision for leasing coal, oil, and gas rights under proper restrictions. If the additional force of special agents and mining experts I recommend is provided and well used, the result will be not only to stop the land frauds, but to prevent delays in patenting valid land claims, and to conserve the indispensable fuel resources of the nation."

The President's recommendation to amend the laws in the direction of leasing instead of selling did not meet with the approval of Congress, which adheres to the traditional national preference for private ownership. President Taft favours leasing.

The Commissioner of the General Land Office in his report for 1909 to his superior, the Secretary of the Interior, says, under the heading "Coal Land Legislation":—

"Attention is called to this because of the demand for the conservation of the natural resources, and because of the entire inadequacy of present legislation either for the conservation or for the proper development of either coal or oil lands. In his Message to Congress at the beginning of the first session of the Sixtieth Congress, President Roosevelt endorsed your recommendation in the following words:—

"'In my judgment the Government should have the right to keep the fee of the coal, oil, and gas fields in its own possession and to lease the rights to develop them under proper regulations; or else, if the Congress will not adopt this method, the coal deposits should be sold under limitations, to conserve them as public utilities, the right to mine coal being separated from the title to the soil.'

"After this endorsement of your recommendation, President Roosevelt, recognising the absurdity of present limitation in regard to area, added:—

"'The regulations should permit coal lands to be worked in sufficient quantity by the several corporations. The present limitations have been absurd, excessive, and serve no useful purpose, and often render it necessary that there should be either fraud or else abandonment of the work of getting out the coal.'

"The conditions which existed then exist to-day, and the situation which is thus created, and which was recognised by President Roosevelt, is as intolerable now as it was then.

"Any legislation in regard to the disposal of coal lands by lease or otherwise, should contain a strong anti-trust clause, and a provision which would prevent any agreement to abstain from mining the coal. If it should be determined to lease on a royalty, then unless such a clause be inserted, so that open competition may be maintained, the charge of the royalty will mean nothing more than that the public will pay the additional price. This would not in any way relieve the situation."

The result of the agitation so far has been that, as the administration could not get a law through Congress which met with general approval, President Roosevelt used his executive authority to withdraw all coal lands from entry, pending contemplated legislation and revised regulation. No new laws have been passed, but the Interior Department, through the Geological Survey, has been revaluing all the unceded coal lands in the public domain, assigning a specific value to each coal area, based upon the quality of the fuel, ease of extraction, facility for transportation, etc. The task is a difficult one, especially when applied to Alaska, where there are undoubtedly very large coal resources, but

Hosted by Google

where little or no work has been done to determine the extent to which faulting has disturbed the beds or modified the character of the coal.

The agitation about the disposal of coal lands applies only to the quantity still under control of the Federal Government—viz., that of the Rocky Mountains and Pacific Coast section. Elsewhere in all the older States, except Louisiana,* the lands and the minerals beneath them, have become private property under the English common law rule.

The area of the coal lands of the United States is estimated by the United States Geological Survey at 496,776 square miles, of which 480 square miles consist of the anthracite coal lands of Pennsylvania, 148,609 square miles of lignite, leaving 250,051 miles of bituminous coal.† The same authorities estimate the quantity of coal of all grades contained under that area as follows:—

to be almost everywhere sold at lower figures than prevail in the metallurgical centres of Europe. Coal from many of the districts in the east, south and middle-west, is sold on the cars at 80 cents to $1 per ton of 2,000lbs., and $1.25 has been a high price in the west.

The conservation of the national resources of the country has recently become a prominent political issue, and has passed out of the domain of scientific inquiry and calm discussion into that of bitter partisan strife. That the laws are too liberal and too loosely administered is becoming the general opinion; but they have, from the point of view of national growth, been so eminently and conspicuously successful, that even those, who are most keenly sensible of their defects, hesitate to call a halt of the national progress by trying legislative experiments with them.

Mr. Ballinger's report as Secretary of the Interior for 1909, however, reflects the popular opinion when he makes strictures on the operation of the old land laws and recommendations for the future. He says:—

ORIGINAL COAL SUPPLY.

	Area.	Amount Easily Accessible.	Amount Accessible with Difficulty.	Easily Accessible and Available.
	Sq. Miles.	Short Tons.	Short Tons.	Short Tons.
Anthracite and bituminous . .	250,531	1,176,727,000,000	505,730,000,000	1,176,727,000,000
Sub-bituminous	97,636	356,707,000,000	293,450,000,000	..
Lignite	148,609	389,545,000,000	354,045,000,000	216,252,000,000
Total . . .	496,776	1,922,979,000,000	1,153,225,000,000	1,392,979,000,000

No large section of the country, except the New England States and California, is deprived of the blessing of its own fuel supply. New York and New Jersey are dependent on their neighbours for coal, but this dependence is really geographical, not economical.

This wide and almost uniform diffusion of the essential element of industrial development has contributed largely to rendering possible the material progress of the country; while at the same time it has been politically a unifying force by diffusing manufactures and reducing the dangerous sectionalism, which at one time grew out of the prevalence of localised agricultural and manufacturing interests and prejudices. The large area of the coal-fields, as well as the favourable structure and deposition of the bituminous coal-beds (the bituminous beds being generally horizontal), has enabled coal and coke

"The proper use and disposition of the public lands have been questions involving no little legislative as well as administrative difficulty from the beginning of their history. They were, during the earliest administrations, treated as a national asset for the liquidation of the public debt and as a source of reward for our soldiers and sailors. Not until the discovery of gold on the Pacific slope did the policy change for one of exploitation, by which our citizens were encouraged to develop the mineral and agricultural resources of the public domain on condition of receiving limited areas at a nominal cost. For similar reasons, railway and wagon-road grants were liberally donated by Congress in order to add facilities for the opening up of these almost inaccessible regions.

"The railway grants generally were limited to non-mineral lands, except such as contained coal and iron, which latter minerals were taken to be

essential for railway construction and operation. New States were, when admitted, liberally endowed with public lands for school and other purposes; so that, out of a public domain in 1860 of 1,055,911,288 acres (Alaska then not belonging to the United States), we now have only about 731,354,081 acres, confined largely to the mountain ranges and the arid and semi-arid plains, except lands within some of the Indian reservations and the 368,035,975 acres of undisposed-of land in Alaska.

"All of the principal land statutes were enacted over twenty-five years ago; the Homestead Act, the Pre-emption and Timber Culture Acts, the Coal Land, and the Mining Acts for the aid of the industrious prospector, were among the earlier Acts of this nature.

"The liberal and rapid disposition of the public lands under these statutes, and the lax methods of administration which for a long time prevailed, naturally provoked the feeling that the public domain was legitimate prey for the unscrupulous, and that it was no crime to violate or circumvent the land laws. It is to be regretted that we, as a nation, were so tardy to realise the importance of preventing so large a measure of our natural resources passing into the hands of land pirates and speculators, with no view to development looking to the national welfare. It may be safely said that millions of acres of timber and other lands have been unlawfully obtained, and it is also true that actions to recover such lands have in most instances long since been barred by the Statute of Limitations. The principal awakening to our wasteful course came under your predecessor's administration. The bold and vigorous prosecutions of land frauds, through Secretaries Hitchcock and Garfield, have restored a salutary respect for the law, and the public mind has rapidly grasped the importance of safeguarding the further disposition of our natural resources in the public lands in the interest of the public good as against private greed. Notwithstanding this, it is necessary to continue with utmost vigour, through all available sources, the securing of information of violations of the public land laws, and to follow such violations with rigid prosecutions.

"In this present policy of conserving the natural resources of the public domain, while development is the keynote, the best thought of the day is not that development shall be by national agencies, but that wise utilisation shall be secured through private enterprise under national supervision and control. Therefore, if material progress is to be made in securing the best use of our remaining public lands, Congress must be called upon to enact remedial legislation."

These strictures are hardly fair, and are perhaps too sweeping. The old laws were framed to encourage the development of the country. As is the case the world over, certain men of exceptional foresight and ability used them to secure from the public domain, at a trifling price—but not necessarily or generally by fraud—large areas, especially of coal, oil and mineral lands, which when developed have proved, especially under the protection of the tariff, of enormous value. Their value was not appreciated when the laws were made, and these laws did not prevent any citizen who came into possession of land as a gift from the State or as entryman of a homestead, or as the purchaser of a quarter section of coal lands, from selling it to a corporation, once he had acquired a patent. While some coal lands were probably acquired under the Homestead Act, and then disposed of as coal lands, the Government thus being defrauded out of $15 an acre, most coal and mineral lands have been legally acquired with the land or from the original locators, or under old Mexican grants in Colorado and New Mexico, by the only holders who could work them safely and economically, by modern mechanical methods. The law-makers of the first statutes, and the many legislators who have, since conditions have altered, recognised the defects of the old laws and yet have not possessed the courage to amend them, were more at fault than the men, whose accumulation of such stupendous wealth under these laws has alarmed the public. If they had not developed the country's resources, there would not have been over 80,000,000 of people to upbraid them. Mere technical evasion of the laws, admittedly defective, should not be laid as wilful infraction to the charge of the men who have built up the great national industries. That in the rush for wealth and the production of quantity there has been waste is beyond question; but economy of necessity follows experiences of waste and of knowledge how to avoid it, and none are more anxious to save than the big financial industrial corporations. Both in America and elsewhere domestic waste far exceeds industrial waste.

That these laws should have remained so long unamended, while such radical changes have taken place in the industrial condition of the country, is attributed by the Public Land Commission to the public "dread of the introduction of unfamiliar requirements, and the fear that new enactments may recognise physical conditions even less than present ones, and may be even less suited to the needs of the country. By the use of practice, sanctioned by custom, the people have heretofore been able to get along fairly well; any change in their mind is associated with more difficult requirements, and they dread innovations which may hinder rather than help home-making."

The Railroad Policy of the United States.

Every modern community the world over has depended largely on its railways and its railway policy for the speed with which it has developed. The early railway legislation of the United States, like that affecting the sale of agricultural and mineral lands, was framed with the motive of encouraging the building of roads rather than of controlling capitalisation or regulating traffic. It answered its purpose, for the activity in railroad building has been prodigious. It has not only kept pace with the development of the country's industries, but has really in most sections helped to create them. As one result, Meyer says* truly that "railway legislation in the United States is full of inconsistencies and anomalies, spasmodic expressions of legislative impulses, and the futile attempts of administrative bunglers." This was almost unavoidably the case, and was in part due to constitutional necessities which gave control only of inter-State railroads to the Federal Government, and permitted it to legislate only on inter-State traffic or the management of inter-State roads. As, however, the handling of mails falls within the province of the Federal Government, and as the great bulk of business, and far the greatest number of rates, are inter-State, the interference of the Federal Government has steadily increased. And if the States would waive their rights to regulate inter-State roads and traffic, Federal legislation, as it is likely to be more consistent than State legislation, would probably be favoured by most railroad managers. Absolute Federal control of railroads would be in line with the present centralising tendencies.

Another reason for the confusion in railroad legislation is the same reason that accounts for many of the anomalies in American life and in American municipal and State politics. The railroad system expanded, and the cities and the country's industries grew more rapidly than remedies for the correction of irregularities could be applied. For in the United States, as in every country where a vigorous population with exuberant energy preceded organised law, there is restlessness under regulation. The temper engendered by being a law unto one's self, becomes temporarily a trait of national character.

Meyer thus briefly describes the rise and progress of Federal legislation:—

"During the first half of the nineteenth century Federal railway legislation dealt chiefly with rights of way through public lands, and with the remission of duties on railway materials imported from abroad. The Pacific Railway agitation was begun during the first and continued into the third quarter of the century. The first land grant Act was passed in 1850. In 1866 the 'charter of the American railway system' became a law. It provided that 'every railroad company in the United States whose road is operated by steam, be and is hereby authorised to carry upon and over its road, boats, bridges, and ferries, all passengers, troops, Government supplies, mails, freight, and property, on their way from any State to another State, and to receive compensation therefor; and to connect with roads of other States so as to form continuous lines for the transportation of the same to the place of destination.' In 1868 the House Committee on roads and canals—the new committee to handle railway legislation did not appear until several years later—submitted a report in which strong reasons were advanced in favour of a liberal interpretation of the powers of Congress over inter-State commerce. The committee had been instructed to inquire whether Congress had power to regulate inter-State railways so as to secure safety of passengers, uniform and equitable rates, and adequate connections with other railways. An affirmative answer was given to every one of these points of inquiry, but the committee did not report a bill. This they refused to do because the requisite facts for the drafting of such a bill were not at hand. Instead, it was recommended that another committee be appointed to collect the data necessary for intelligent action. Meanwhile the Patrons of Husbandry had come upon the scene. From 1867 to 1872 the founders of the order struggled chiefly alone. In 1872 the State Grange of Iowa was founded, and by the close of that year about thirteen hundred granges had been organised in various parts of the country. In two years more the order had spread over the whole country, with an aggregate of over 20,000 lodges. In 1874 the Grand Master's address alluded to exorbitant and varying rates, discriminations, and uncertainties. 'When we plant a crop we can only guess what it will cost us to send it to market, for we are the slaves of those whom we created . . . In our inmost soul we feel deeply wronged at the return made for the kind and liberal spirit we have shown them' (i.e., the railways). Sentiments like these, frequently expressed in vehement language and repeated time without number in subordinate granges, created a profound influence on public opinion and political parties. Congress was petitioned to establish a department of agriculture, to revise the patent laws, improve the Mississippi River, and above all, to enact suitable railway legislation. 'We hold each senator and representative responsible for his action upon the subject-matter' set forth in the resolutions. The President's Message of December, 1872, gave the stimulus to the appointment of a Senate committee of seven, known as the Windom Committee. The report of this committee 'is interesting

* The best, short concise treatise on United States railway legislation is "Railway Legislation in the United States," B. H. Meyer, Ph.D. (The Macmillan Co.).

Hosted by Google

because it contains the first presentation of a comprehensive plan of regulation of the whole subject of commerce between the States, as it has constituted itself since the introduction of the railway.' The primary view of the report was low rates and the preservation of competition. The crisis of 1873 tended to divert attention from discriminations and other abuses to the absolute level of rates, it being assumed that cheap rates would afford relief. Among the measures recommended by the Windom Committee were publicity of rates, prohibition of combinations, stock-watering, and a greater charge for a shorter haul over the same line, reforms in the shipment of grain and in the operation of freight lines, and, finally, the establishment of a bureau of commerce."

But it was not until 1886 that the Cullom Committee reported in favour of a Federal commission to regulate commerce. This followed a recent ruling of the Supreme Court, in the case of Munn *vs.* Illinois. This ruling was to the effect that "When the owner of property devotes it to a use in which the public has an interest, he in effect grants to the public an interest in such use, and must, to the extent of that interest, submit to be controlled by the public, for the common good, as long as he maintains the use. He may withdraw his grant by discontinuing the use."

The Inter-State Commerce Commission, with duties and functions as prescribed in the Act of 1887, was the result of the report of the Cullom Committee. The Elkins Act, the Hepburn Act, and amendations almost from year to year, have steadily enlarged the powers of the committee, as well as imposed severer penalties for infractions of the law. Besides possessing the right which the original Act conferred, to adjust unreasonable rates on complaint of an injured person or community, the Act known as the Hepburn Bill gives the Commission the power to investigate, at its own initiative, rates which they consider unjust. And a Court of Commerce has been created, to which appeal from the rulings of the Commission can be made so as to secure prompt action. The whole tendency of legislation, if not in the direction of State ownership, tends towards stricter Federal control over both the rate-making and the operation of the railroads; the issuing of securities as well as the issuing of passes, and the abolition of discrimination in any form.

The Cullom Committee's report and the first Act, framed on its recommendations, aimed at correcting the great discrepancies in rates between the long and the short haul, and the allowances which might be made to compensate for water and other competition. The difficulties of adjusting these complications have been so great that the problem is still unsolved. They grow out of the great distances covered by even a single system, and still more by connecting roads, the striking variation in the physical features of the different sections of the country, and the corresponding difference in the cost of operation. The wide range in the price of labour, and many other disturbing factors, make the adoption of a scale of absolutely uniform rates inapplicable, and therefore the problem of adjusting equitably such a host of differences on a total mileage of 230,000 miles is a task requiring not only enormous labour, but the exercise of extraordinary wisdom and skill. The Inter-State Commerce Commission has heretofore performed its difficult duties with such fairness and ability, and attempted to enforce the law so impartially, that the railroads have felt the benefit of escaping from the importunity of the shippers demanding illegal preference, and have greatly benefited instead of suffering through the passage of recent restrictive legislation. Pooling, or "combining in restraint of trade" (a very ambiguous term capable of wide interpretation), being strictly forbidden under the Sherman Act, the only remedy against the ruinous results of unbridled competition—or, at any rate, the one adopted—has been actual consolidation into great systems by purchase. The further this is carried the nearer it brings any country to State ownership. The political consequences of State ownership most people dread, considering that one million and a half of men—most of them enjoying the franchise —are on the pay-rolls of the railroads.

In the early days all railroads were built under separate State charters, but ere long most States and Territories passed general railroad laws. These differ widely in their provisions, so much so that the aim of some States has been to tempt railroad companies to incorporate under their laws by reason of the liberal terms they offer in organisation fees and in tax on capitalisation. These fees flow into the State's treasury. But a State charter does not imply that a single mile of the chartered road is built in the State, nor do all State statutes require that roads traversing a given State must be incorporated under the laws of that State, though every railroad operating in any State must obey its laws, and regulate their local rates, both passenger and freight, in conformity therewith. Almost every railroad, therefore, is subject to both State laws and Federal statutes. But, despite all these incongruities, the incorporation of railroads, and

Hosted by Google

their construction under general statutes instead of under special charters, has tended towards the rapid development of this method of carriage, and towards the restrictions of inland water transportation.

The legal expense of incorporation is everywhere light, in striking contrast to the experience of European roads. Mr. Acworth, in his "Railroad Economics," calculates that the initial expense of securing the passage of a railroad charter through the British Parliament is £5,000 per mile. The actual cost of some American railroads, as first built, probably has not much exceeded that sum; for the first cost and their actual present value bear no relation to one another. Most roads have been built, in anticipation of freight and passenger traffic, with light rails on a poorly ballasted roadbed; with wooden culverts, and bridges only strong enough to carry comparatively light rolling-stock. As traffic increases, the road in all its features is improved, and large sections are generally rebuilt with lighter grades and reduced curves. The fixed charges of a new road with light traffic thus constitute a burden more easily borne than if it had been at once constructed on a higher standard.

This condition is one of the factors which have assisted the American roads in carrying freight at a lower rate than that of any other country; but to secure these rates the customers of the railroad have to forfeit some advantages enjoyed by others—notably punctuality of delivery. Still, the progress of the country has been due in great measure to the cheap transportation of commodities.*

Class rates are much higher, and there are notable discrepancies in the charges made for hauling the same distance between different points, and still greater incongruities between the tariffs on long and short hauls, especially when the long haul is to points where water competition has to be met.

As most long distances are covered only by transportation over several roads, rates and classifications are fixed by traffic associations, and divisions of the through rate are made by mutual understandings of the roads affected. As yet the Inter-State Commerce Commission has not interfered with the divisions, considering that the public is directly interested only in the rate itself.

The effect of the above-described policy and the liberal laws enacted after the Civil War is reflected in the growth of population. At the close of the Revolution (say in 1780) the population of the United States was 2,781,000. The census of 1800 gave 5,308,483 as the total population. It grew slowly for the next twenty years, for the ten years' growth to 1810 showed an increase to only 7,229,881; and in 1820 it was 9,638,453. It had risen when the Civil War broke out to 31,443,321. The census of 1880 shows an increase to 50,155,783; but that of 1900 a leap to 75,994,575, and the last census, that of 1910, places it at 91,972,267.

The population of the original area of the revolting colonies at the census of 1900 was 33,553,630, but it consisted of only about one-fourth of the present area of the United States.

Year.	Population.	Coal Production.	Consumption of Coal per head.
		Tons.	Tons.
1860	31,443,321	16,139,736	0·51
1870	38,558,371	36,806,560	0·96
1880	50,189,209	76,157,944	1·52
1890	63,069,756	157,770,963	2·50
1900	76,303,387	269,684,027	3·53
1910	91,972,267	444,203,801	4·83

The density of population at present in the older eastern and southern States is nearly twice as great as that of the country at large, indicating that the centres of industry are still not far from the Atlantic seaboard; but the trend of population and manufacturing is westward towards the rich prairie lands, yielding food supplies, which are being more and more manufactured into condensed products, and towards the minerals of the Lake Region and the Rocky Mountains. New England and the middle Atlantic States no longer monopolise manufacturing. Cotton is now made into cloth where the cotton is grown. The largest iron and steel works have been built near Chicago at Gary, where the Lake Superior iron ores are discharged directly into the furnaces from the ships. Meat-packing plants are established at Kansas City,

* The average rate of transporting coal in the eastern and middle States is about ·35 cents per ton mile, or less than one farthing per ton per mile. In the western States it is about one farthing per ton mile. Crude copper is carried from the great copper mining and smelting centres of Arizona, Utah and Montana at \$8 (£1 12*s.*) for an average distance of 2,000 miles, and pig-iron enjoys an average rate in the eastern, southern, and middle States of ·5843 cents per ton mile.

Hosted by Google

central to the corn-growing States. This economical conversion of raw material into specialised manufactured form established near the place of origin, is rendered possible by the very wide distribution of coal and the low transportation charges on certain commodities. The table (p. 39) illustrates the manufacturing activity of the country, for the coal consumption per head is a true gauge of the growth of manufactures.

The coal consumed is the coal produced, as very little is exported.

The rate at which the coal is consumed per head of the population is out of all proportion to the growth of population, and even the increase in the production of coal itself. In England the coal consumption per head of population has shown but slight increase. It has been as follows:—

	Coal Raised.	Domestic Consumption.	Population.	Domestic Consumption per head of Population.
	Tons.	Tons.		Tons.
1870	110,431,192	112,603,503	32,177,550	3·499
1880	146,946,409	123,066,763	34,622,930	3·554
1890	181,614,288	142,954,016	37,484,764	3·814
1900	225,181,300	166,776,213	40,521,371	4·075
1909	263,774,373	177,737,306	—	—

From the final report of the Royal Commission on Coal Supplies, 1905, Part I. p. 27.

The consumption of fuel per head in England is not notably different from what it is in the United States, but England within the period under revision had already developed her manufacturing industries, and therefore has not proportionately increased her coal consumption per head. In the States we have been actively growing. But if the table of English consumption is to be accepted as a basis for prediction, it indicates that after a certain period, stability, rather than increase, becomes the rule, and that, therefore, consumption in the United States will not proceed in future in the same ratio as heretofore.

The activity of the Patent Office and the large proportion of patents taken out by the working mechanics, is a measure of the ingenuity of the people at large, and this and many other powerful but undefinable influences have combined with the written laws to shape the economic destiny of the Republic, especially since the great awakening in the sixties. But to discuss them would lead me out of the dominion of facts into the region of speculation.

DISCUSSION.

Lord Sanderson, G.C.B., K.C.M.G., after thanking Mr. Douglas for his paper, said it made one feel proud to know that the American nation, the progress of which had just been described in such glowing terms, originated from this island. As Mr. Douglas had proceeded with his account of the development of the United States, he (Lord Sanderson) confessed he wondered what would have happened if the United States had not separated from England—whether there would now be a British Cabinet in London, and if so what its composition would be. One or two points in the paper had struck him as being particularly interesting, the first being with regard to the question of land. Americans had always had the reputation of being very good men of business, and their Government had done exactly what other governments had in the past done, namely, when they had a large amount of land at their disposal they distributed it to private owners. That had happened almost all over the world. There was one place in particular where it was in the course of happening at the present time, namely Russia, where, for a long period, the tenure of land was communistic; but now it had been found that the only effective means of advancing husbandry was by the land being given into private ownership. At the present moment there was in this country a school of social reformers which maintained that the only way in which the land could possibly be utilised to its full advantage was by bringing it into the hands of the Government. There might be arguments in favour of that course, but it was at least a matter for very careful examination. With regard to the question of forests, the author had said there was much waste in America in that respect, but he (Lord Sanderson) was afraid that if any country, however business-like it might be, had any particular article in great abundance it would waste it. He remembered travelling in a railway train in this country with an American who, as they passed through the country, said he wondered why more wood was not used in England for the construction of houses. He replied that there was not much wood in this country, and that a good many other materials were more

Hosted by Google

available for building purposes; and, as the author had observed, the tendency in America at present was to use much less wood in the construction of houses. No doubt if at any time the waste of wood in America was found to be of a really serious nature, the Government there would find means of stopping it. The same applied to the question of coal. As the author had explained the mining laws of America and how impossible they were, he (Lord Sanderson) had thought it was an instance of the great patience which was at times shown by the American citizen; but at the end of the explanation it had turned out that notwithstanding these laws the American people obtained all the coal they wanted. He ventured to ask whether the rapid increase in the average consumption of coal by every individual did not mean that wood was being less used for fuel? Referring to the question of trusts and the railways, he thought that what had been stated was a remarkable illustration of the fact that whatever was done to try to stop people from using their money in a way which turned it to the best advantage, capital invariably foiled any such attempt. When people said that it was extraordinary how small holdings in England had disappeared by being gathered up by greedy landlords, it really meant that the small holdings did not pay. It might be that at present a way was being found by which they would pay, namely, by co-operation among small holders, but as long as small holdings did not pay they would necessarily disappear. People might be stopped from co-operating, but if they were prevented from co-operating they would naturally combine. In this country a more elastic system prevailed with regard to railways. Parliamentary committees endeavoured to ensure that there should be a certain amount of competition, but that this competition should not be excessive. They had not always been entirely successful; there had been a tendency to very expensive competition, and now the railways were beginning to combine, and there was a good deal of jealousy on the part of the public as to their combination. Whether it would result in the acquisition of the railways by the State was a matter for the future to decide, but he entirely agreed with the author that the voting question was a very serious element in the matter, and that though it might be possible to nationalise railways in England, as in Germany, in the United States the enormous extent of the railways made it practically impossible.

The CHAIRMAN said Lord Sanderson had pointed out that Englishmen ought to be proud of the fact that the nation which had done the colossal things to which the author had referred that night, had sprung from our own stock. He (the Chairman) thought this country might also not only be proud of that fact, but that Americans spoke its language, followed its laws, and had very much the same ideals; and also of the fact that Great Britain had some share at the beginning in helping the United States towards their present development. The author had pointed out that at the time of the negotiation of the treaty of peace, at the end of the revolutionary war, Great Britain behaved to the new Republic, not in a niggardly or grudging fashion, but in the most broad-minded way. That was a very wise thing to do, and it had a very great effect towards helping the development of the United States. Great Britain put an immense tract of country at the disposal of the United States, which the latter might not have otherwise had. He thought that was a thing which was a legitimate object of satisfaction and pride to this country. He had been reading the other day an essay by Mr. Choate, the late American Ambassador in London, one of the best of the many good men the American nation had sent over here, and that gentleman used the phrase that this country's conduct in the negotiations which ended that war "was wise, moderate, and statesmanlike." The author had said that the United States would prove to be a great rival to Great Britain in the future. He (the Chairman) had no doubt that would be the case, and he did not think Englishmen would in the least mind that being so, but he would like to say that, so far as his reading of history went, it was a mistake to say too much on that point, and that the case could very easily be overstated. Although England and the United States had had their fraternal differences, throughout the feeling between the two nations had been an extremely friendly one. It might be said that we had fought more than once; so had the English and Irish, and the English and Scotch. He would like to point out that there were three things which had always struck him as being very remarkable: the spirit in which the two peoples approached the parting of the ways—the revolutionary war; the spirit in which that war was closed by the treaty of peace; and the spirit in which the two nations had since behaved towards one another. He thought it was very remarkable that when the war broke out it was extremely unpopular in this country, as everybody who read the history of the times knew. One would find, if one read Trevelyan, for instance, that it was exceedingly difficult to get the people of Great Britain to join in the war against the United States, and it was one of the curious ironies of history that the employment in that war of foreign troops—Hessians as they were called—which caused great bitterness on the other side of the water, was due to the fact that Englishmen would not enlist to fight against their kinsmen. Trevelyan pointed out that the man who was at the head of the army, Lord Amherst, and the man who was at the head of the navy, Keppel, refused to serve against the colonists. The great Pitt himself had a son who had just gone into the army, and when the war broke out Pitt withdrew him from the army. All that was not want of patriotism; because, before that revolutionary war, and also just afterwards—twenty years in each case—this country had great wars with foreigners, and then Great Britain poured out her blood and her treasure like water. Against America, however,

Hosted by Google

people would not enlist, and the King had to get Hessians. There was a good deal of the same feeling on the other side. The greatest diplomatist America ever had produced—Benjamin Franklin—was as proud of the British Empire as anybody, and did his utmost to prevent its disruption; and he (the Chairman) had not the slightest doubt that George Washington drew the sword against his old comrades in arms with just as much reluctance and sorrow as, eighty years later, Robert Lee drew his in favour of his own State, Virginia, against the United States. Since the treaty of peace was signed, this country and the United States had had their differences, but it was a remarkable fact that for nearly 100 years there had been no fighting between them. He would point out that that immense borderline which separated the United States from Canada, 3,500 miles in length, was not bristling with forts and bayonets and soldiers from end to end. Nothing of that sort was to be seen—no sign of mutual distrust or hostility whatever. That was a remarkable sign of the general feeling which had existed between this country and the United States ever since 1814. Such facts were very remarkable, and ought to make Englishmen feel that they regarded that great development not in the least with any feeling of jealousy, but, on the contrary, with feelings of deepest sympathy and greatest possible pleasure.

A vote of thanks to the author for his interesting paper was then put and carried unanimously.

Dr. Douglas, in reply to Lord Sanderson's question with regard to coal consumption, said he did not think the consumption of wood for domestic fuel was greatly decreasing, because if the coal consumption and the railroad traffic of the United States in any given district were taken, it would be found that the coal was going to be used in industrial pursuits, and not for domestic purposes. Only a small quantity of anthracite mined in Pennsylvania was used as domestic fuel in preference to wood. With regard to railroads in the United States, there was little doubt that the Inter-State Commerce Commission had been of benefit. There was little doubt, likewise, that the general railroad Acts, under which railways could be built without special charters, had had an immense influence upon the rapidity with which railroads had been built. It was clear that that principle could not be applied in this country. As had been mentioned in the paper, Mr. Acworth had pointed out that every railroad built in the United Kingdom cost, for Parliamentary Bills, £5,000 a mile before a spike had been driven. £5,000 a mile had built a very large proportion of America's western railroads—as first constructed. They were built in the lightest kind of way to carry a light traffic over heavy grades, but they answered the purpose for which they were built—they developed the territory, and as the territory and freight developed, then the road was reconstructed from beginning to end on a totally different system and raised to the grade of a high-class standard road. But, of course, the state of affairs, which was perfectly applicable in a new and undeveloped country, was absolutely inapplicable to England.

THE TONNAGE OF LINERS.

Attention was recently directed in the *Journal* to the rapidly growing dimensions of liners, and it was observed that "it looks as if Lord Pirrie's prediction that we shall see 1,000-feet ships will soon be realised." This comment has induced Dr. Corthell to send an interesting letter, covering a copy of his report for the International Congress of Navigation (1912), on the size which should be given to maritime canals, and the probable size of ocean vessels of the future. Dr. Corthell contends that in the construction of maritime canals the necessity for size has not been adequately appreciated. The rapid increase in tonnage was not generally foreseen. The increase in the dimensions of commercial vessels has not reached its culminating point, nor is it entirely confined to liners trading from Europe to the port of New York. In Dr. Corthell's opinion, within the next thirty years there will be ocean vessels of 1,100 feet by 110 feet by 40 feet, with naturally a margin over these dimensions in the chambers of locks, and in the open sections of canals. One of the most interesting studies in connection with the dimensions of maritime canals is the development of the various plans of an inter-oceanic canal across the American isthmus and the natural development of the Suez Canal; a study that will show how little the best experts of the past appreciated the size of the ships that would use the canals. In Dr. Corthell's opinion, within a few years the Suez Canal will have to be deepened, in order to retain its traffic, to 42·6 feet at least, allowing for a draught of 39·4 feet, with corresponding width to allow for a passage, in two lines, of vessels of 25,000 tons. Note the gradual and reluctant concessions to the steamships in the matter of draught. The Suez Canal Company authorised, in 1869, 24·6 feet draught; in 1890, 25·5 feet; in 1898 it widened the Canal from 72 feet to 121 feet; in 1902, 26·2 feet draught; in 1906, 26·3 feet; in 1908 the Canal was deepened to 31·2 feet; and 28 feet was the authorised draught in January 1911. Dr. Corthell predicts that the dimensions of commercial and naval vessels will in the near future reach what now appear excessive figures, since the present average dimensions of the twenty largest commercial steamships are 28,018 gross tonnage, 725 feet length, 80 feet width, and 35 feet load draught, while in 1881, only thirty years ago, the corresponding dimensions were 4,900 tons, 460 feet, 45 feet, and 24 feet. There was not one steamer in 1880, 500 feet long, if the "Great Eastern" is excluded; the largest steamer was 5,490 gross tonnage, 488 ft. 6 ins. long, 44 ft. 2 ins. wide, and about 24 feet load draught. The largest steamer now is 50,000 gross tonnage, over 900 feet long over all, 96 feet wide, and the maximum

Hosted by Google

draught is about 38 feet. Dr. Corthell concludes his interesting survey of steamship and canal capacity and requirements by the observation that the engineers who design, construct, and enlarge canals and ports, should realise the situation, and use their influence with the Governments of the world to build wisely and amply for the future ships of the world, both commercial and naval.

ARTS AND CRAFTS.

The Stevens Exhibition.— The opening of the Loan Collection of works by Alfred Stevens, which has been organised in connection with the presentation to the Tate Gallery of Professor Lanteri's portrait bust of the artist, and of a reproduction of the famous Dorchester House chimney-piece, is an event of real importance to all those interested in decorative art. Most people know, of course, that the Victoria and Albert Museum possesses a number of Stevens' drawings which are now very well shown, and that there are also some in the permanent collection at the Tate Gallery. But a special exhibition always gives a certain fillip to popular interest; and this one will doubtless rouse many of those who are usually quite content to know that Stevens' drawings are in London, and that they can study them at their leisure if they so desire—and therefore never take the trouble to go and look at them—to make an effort to see works which will only be visible to the general public for a couple of months. One critic, in his notice of the exhibition, has scornfully complained with reference to Stevens' work for Messrs. Hoole: "They employed our first sculptor as a designer!" as though that were a kind of crowning indignity. One can understand that a sculptor might feel it was so—and, of course, no one can help regretting that the genius of so great an artist was not recognised and appreciated during his lifetime, but the fact remains that, whatever else Stevens may have been, he was pre-eminently a designer, and a giant among designers. That much is apparent not only in his models, but in every line of his drawings. Many of the sketches shown at the Tate Gallery are so rough as to appear at first sight little more than scribbles, but one has only to look at them attentively to see how the draughtsman's first thoughts have been of the design, of the relations of the masses, of the decorative effect. Designers naturally do not all work on exactly the same method, and a cast-iron system of training in design is what everybody wants to avoid; but a careful study of Stevens' work ought to do a good deal towards showing any open-minded and intelligent person at least one of the reasons why so much of the design teaching of the present day fails to produce the desired results.

There is another point about Stevens' work which it is peculiarly interesting to note at the present moment—its individuality. Stevens was, of course, a disciple of the Renaissance; he was a classicist through and through; he had worked for nine years in Italy, and knew and loved the finest masterpieces of Italian Renaissance art, and his work makes it abundantly plain that his study of Michael Angelo was of the deepest. Indeed, it is almost impossible to imagine Stevens apart from his Italian training. And yet the man was no copyist of Italian models, but strikingly himself. It is the fashion of the present day to decry the study of old work as cramping to individuality. It is possible that without such study Stevens might have been a great artist, but his work inevitably gives the impression that without it he would never really have found himself. The old work had grown to be part of his own being, so perfectly had he assimilated it. The Dorchester House fireplace, for instance, quite evidently owes something to Michael Angelo, but it is not an imitation of the Italian master, nor the work of a mere disciple—it is an expression of the genius of Stevens himself, who was happy enough to have fallen in with the style which suited him in his youth, and who owed, not of course his genius, but his power of self-expression very largely to that fact.

The works collected at Millbank include, besides a quantity of sketches, the model for the suggested decoration of the dome of St. Paul's Cathedral, a small plaster sketch-model for the Dorchester House fireplace (which it is interesting to compare with the final version), a number of modelled designs for fire-irons, friezes, etc., a table of his design and various more finished drawings, amongst which the designs for a chalice and a tazza are perhaps the most remarkable.

The New Trophy for the Buffs.—Trophies are, artistically speaking, so often atrocities that it seems at first a far cry from the Stevens Exhibition to the new trophy for the Buffs. As a matter of fact it is nothing of the kind, for Miss F. H. Steele, who is responsible for it, is not only a pupil of Professor Lanteri, whose respect for Stevens is well known, but the modeller above all others who has a reverence for Stevens' work; and it is no reflection on her originality to say that this particular piece would not have been just what it is had that artist never lived and worked.

The trophy is presented to the officers of the 2nd Battalion of the Buffs by those officers of the battalion who served during the South African War, 1899-1902, and Miss Steele's design was chosen from amongst many others sent in for competition. Mr. Plante, of Regent Place, is the maker, but the artist has supervised the execution from start to finish, and has identified herself with the work throughout. The base, which bears on its outer rim the names of the battles in which the regiment has distinguished itself, is massive, and in a way recalls a fine old salt or tankard; at its two sides are little figure groups representing Kent (since the Buffs is a Kentish regiment) instructing her children in knowledge and in arms, behind which are swags of hops and cherries. On the second member is a spirited rendering of the dragon badge of the

Hosted by Google

regiment and a label inscribed with its motto "veteri frondescit honore." A circular column round which are modelled in fairly high relief four figures symbolical of Courage, Endurance, Loyalty and Mercy, surmounts this member, and forms a support for the dainty little winged figure of Victory standing on tip-toe with her draperies floating behind her, which crowns the whole work. Some of the details, notably the badge, the figures round the column, and the tenderly graceful seated figures of Kent, are extremely good, but the strong point of the trophy is not so much the beauty of individual members or details as the grace and harmoniousness of the whole. The line of the composition is entirely pleasing, and the little groups at the side, instead of marring the general effect, help to steady it; much as well-schemed handles would do. Miss Steele's work is always marked by a feeling for style, and by a dignified restraint, and her latest important piece of work is no exception to the general rule; the ornament and the figures go well together; the piece is not overloaded with detail, and there are no excrescences to interfere with the main lines of the form. The execution, too, is not only good technically, but shows that the artist has been in close touch with the workmen throughout, and that the maker has spared no trouble or expense. It is encouraging to see such a really distinctive and distinguished piece of work —and also to reflect that the officers who chose it had the good taste to recognise its merit. Thanks to them, their regiment has acquired a piece of plate of which it can be justly proud.

Embroidery and Hand-Loom Weaving.—Both at the little exhibition organised by the *Englishwoman*, and held at the Maddox Street Gallery, and at the Irish Exhibition at the Royal Horticultural Hall, there was a good opportunity of seeing what women are doing in the way of embroidery and hand-loom weaving. The most interesting pieces of needlework were the two landscape panels shown by the Cuala industry. They are largely in darning, and only as much stitchery has been employed as was necessary to give the effect, but they are thoroughly satisfactory. The bare tree-trunks in the wintry scene, and the bright white flowers in the summer one, are really most expressive. It is a question whether landscapes are the best things to render in embroidery, but if they are to be done, this is certainly the way to do them. The work of the Windermere industry continues to be characterised by an uncommonly good sense of colour, and the Celtic patterns of the Dun Emer Guild are well considered and carefully worked, but the quantity of so-called "art embroidery," which is by no means as good, either in design or workmanship, as it should be, does not seem to diminish appreciably. The hand-woven stuffs, both silken and woollen, are often very pleasing in colour, and seem to suggest that those responsible for them appreciate the qualities of the materials in which they are working. Some of the simple woven patterns, too, are admirable of their kind. There was not so much lace at the Irish Exhibition as might reasonably have been expected, but some of the crochet was very satisfactory, copied from good models, and used with discrimination. It is a pity that, while a certain amount of good work is shown at the numerous little shows devoted to arts and handicrafts held before Christmas, they are always marred by one or two stalls which cheapen the whole effect of the exhibition.

EMPIRE NOTES.

Australian Railway Gauges.—For some time past the question of making the gauges of the various State railways in Australia uniform has been engaging the attention of the Commonwealth Government. It is proposed that the gauge of all the Australian railways should be the same as in this country, namely, four feet eight and a half inches. The gauge of the Queensland Railway is small, whereas that in New South Wales is four feet eight and a half inches, and that of Victoria and South Australia five feet three inches. In the event of the proposal being carried into effect, Victoria and South Australia will have to lay a third rail, but it will still be possible for these Governments to work off their old stock on the existing gauge, while through trains could be run on the four feet eight and a half inch track. A comparatively short distance of line in Queensland would have to be widened to the standard gauge in order that trains might run from Sydney to the Tweeds Heads, and the tunnels on the line to Southport on the coast will have to be made sufficiently large to accommodate trains running on the standard gauge. The new Trans-Continental Railway from Perth to Adelaide will be built with a four feet eight and a half inch gauge, thus making it possible for trains to run from Perth to Brisbane without a break.

Tin and Diamonds in Bass Straits.—The little archipelago that lies between Australia and Tasmania in the Bass Straits is coming into prominence in mining circles in Australasia. Tin in payable quantities is reported from Cape Barren Islands. Mr. H. Hawkes, well known as an authority on tin in Tasmania, has visited the Islands and reports that a Tasmanian syndicate under the management of Mr. E. Connors is cutting a prospecting tail race in splendid looking tin ground. Other prospectors also, have secured promising claims, and on the lease being worked by Mr. John Fisher, on behalf of Mr. A. Ross, very rich tin has already been obtained. During one week on this property two men were able to mine half a ton. Mr. Hawkes further reports that on other blocks good prospects are being obtained, but these properties are at present handicapped by want of water. Alluvial tin can be got on the beach. Mr. Hawkes speaks very optimistically about the mineral developments of the hills at the back, though he draws attention to the scarcity of fuel for generating steam. He

Hosted by Google

suggests that a geological survey would prove of considerable value, and believes that the fuel question could be solved by electric power or other agencies not requiring a large supply of firing, though fuel can be obtained if a route is surveyed and a roadway cut. Referring to Flinders Island, Mr. Hawkes expresses surprise that the valuable alluvial at Pat's River, the property of the Straits Islands Pastoralists' Association, is lying idle. He affirms that dredging would prove a highly remunerative undertaking, and thinks that it only requires some syndicate with sufficient capital to operate on a proper scale to make this claim a great financial success. Recent prospecting bores seem more than to bear out his opinion. At Tanner's Bay Mr. Doherty has been successful in inducing Melbourne mining people to interest themselves in his venture. Another item of interest concerning the Tanner's Bay district is the reported discovery of diamonds. If this report is true, and diamonds in payable quantities are found, a period of prosperity for the Bass Straits is bound to result.

Aerial Railway for Table Mountain.—For many years past the public of Cape Town have been anxious to have a railway constructed up Table Mountain, and it is interesting to note that during the last month the Cape Town City Council has received a letter from a large firm of contractors, applying for a concession to enable them to construct an aerial railway up the mountain. The contractors suggest that the Council should grant them permission to construct the necessary works on municipal land over the route, which will be either from the neighbourhood of Orangezicht or Rocklands, as determined after the necessary survey has been made. They will also require a sufficient area of ground at the commencement of the line for station and engineer's quarters. Further, they have asked the Council to grant them its assistance to have a half-way house built at the foot of the famous gorge, where a suitable restaurant will have to be erected, and also an hotel on the top of the mountain. The power for the railway will be electric, but, before anything definite can be done, it will be necessary for the Town Council to inform the promoters on what conditions and at what rate they will be prepared to supply current. It is hoped that this agreement will meet with general approval, as it will thereby induce many visitors to Cape Town to go up the mountain, which, at present, can only be accomplished by a tedious climb.

Unusual Weather in South Africa.—East Transvaal has provided an extremely interesting meteorological phenomenon during the month of September. In the first week, quite winter conditions were experienced, with eight and ten degrees of frost every night. A fortnight later the hottest summer conditions prevailed, and the thermometer rose to between 89° and 92° in the shade, day after day, and the nights proved correspondingly close and hot. Statistics showed that the month produced the highest mean maximum shade temperature (80°), and the lowest mean minimum temperature (40·8°), recorded in ten years. Another strange occurrence was the total absence of rain, which, likewise, has never happened during a similar period.

The Canadian Census.—The preliminary statement of the Canadian census is now in the hands of the Dominion Government. Although the figures shown are to be revised, it is generally expected that they indicate very nearly the population of the Dominion. A great deal of disappointment is being felt by those who have imagined that the population would show a much larger increase than it does. The population at the moment is put down at 7,000,000, whereas it was anticipated that it would have been nearer 8,000,000. The population of Quebec is but little over 2,900,000. As each census is taken, a redistribution of seats in the Assembly becomes necessary. It is foreshadowed that, as a result of this, Nova Scotia, New Brunswick, and Prince Edward Island will each lose a member, and Ontario two or three, while the western provinces will gain from twelve to sixteen members. The representation, however, largely depends upon the relative losses of city and rural constituencies.

Canada and the West Indies.—Sir William Grey-Wilson, Governor of the Bahamas, has been on a visit to the Dominion of Canada. Whilst there he took the opportunity of advocating a political union between Canada and the West Indian colonies. The proposal has excited considerable interest throughout the Dominion, but in this country, so far, there appears to have been no pronounced expression of opinion on the subject. Sir William is convinced that such a union would be advantageous to British interests, both in Canada and in the islands. He does not, however, advocate the transfer of the islands *en bloc* to the Canadian Government, but is of opinion that an experiment should be made whereby parts of the Indies can be brought under the rule of Canada. At the back of the suggestion is the question of tariffs, but that need not necessarily affect its political advantage or disadvantage, which must be a matter of Imperial concern. On this point Sir William seems to have no doubt, as he says: "It would be a great thing from an Imperial point of view, tending to a more complete and beneficial relation between the colonies themselves and the Empire."

French Banking Enterprise in Montreal.—French capitalists are realising the large openings for investment in Canada, and consequently a new bank, known as the Banque Internationale, has been opened in Paris and Montreal. The opening in Montreal, following the granting of a certificate by the Treasury Department in Ottawa, was under most favourable circumstances, deposits to the

Hosted by Google

amount of £23,200 being placed with the bank on the first day of business. Business is being carried on at the present moment in the Standard building on St. James Street, but immediate steps will be taken to secure more commodious quarters. Branch offices will be opened at an early date in Quebec, Toronto, and Three Rivers, while one or two others will also be opened in the outlying districts round Montreal. The bank starts with a paid-up capital of £2,055,000, the major part of which has been subscribed in Paris. It is anticipated that it will encourage a constant flow of French capital into Canadian enterprises.

Industrial Expansion in Canada.—Mr. J. Norton Griffiths, M.P., whose knowledge of Canadian affairs is perhaps wider than that of any other member of the British Parliament, recently made an interesting and important statement on the subject of Canadian industrialism. He said: "There is hardly a single branch of trade in this country which could not be fully established in Canada under experienced management, and to reap a full share of business firms would be wise at the outset in sending out their own men and partly-manufactured materials, until such industries attained full development. United States business men are doing this all the time, and the industries which have been started lately in Canada have proved a commercial success in every case. There can be no doubt that the present is the time for action to be taken, for without making invidious comparisons between British and United States business methods, the Americans have shown keen aptitude in taking advantage of numerous openings in the Dominion. The best evidence of the widespread prosperity and the splendid openings that exist is that of personal investigation, and for this purpose special facilities are granted to manufacturers by the Government, and assistance rendered by local boards of trade and bank managers."

NOTES ON BOOKS.

MERCANTILE LAW. By D. F. de l'Hoste Ranking, M.A., LL.D., Ernest Evan Spicer, F.C.A., and Ernest C. Pegler, F.C.A. London: H. Foulks Lynch & Co. 10*s*. 6*d*. net.

Mercantile law is derived very largely from the customs which have gradually grown up among merchants, and which have been from time to time ratified by the decisions of the courts of law. The courts, in settling these cases, have proceeded on the principle that, "with reference to transactions in the different departments of trade, courts of law, in giving effect to the contracts and dealings of the parties, will assume that the latter have dealt with one another on the footing of any custom or usage prevailing generally in the particular department. By this process what was before usage only, unsanctioned by legal decision, has become engrafted upon, or incorporated into, the common law, and may thus be said to form part of it." From the manner of its growth it will be seen that mercantile law is an exceedingly technical business, complicated in each case by the usages of the trade concerned. The present volume gives a lucid and interesting account of it in eleven chapters, dealing with contracts, agency, the sale of goods, negotiable instruments, security and guarantees, insurance, bailments, carriage, merchant shipping, securities, and miscellaneous matters. Each chapter is prefaced by a synopsis, and a very large number of cases are quoted in illustration of the text. The book appears to be an excellent introduction to a very difficult subject, and should prove of much service to those who are beginning to study it.

GENERAL NOTES.

UTOCOLOR-PAPER. — According to a note in *Nature*, the Société Anonyme Utocolor of La Garenne-Colombes, Paris, is now introducing an improved paper under the name of "Utocolor-paper," which has been perfected by Dr. J. H. Smith's investigations, and which, when exposed under a coloured transparency, furnishes a coloured copy of the transparency. The new paper is stated to be much more rapid than the old, and it is free from the odour of anethol, the sensitiser previously employed. The gelatinous coating of the paper contains three dyes, red, yellow, and blue, which are bleached by exposure to light; and if a coloured light is employed, the dye, or mixture of dyes, that matches the colour of the light survives longer than the other dyes, which absorb the light, and therefore a coloured original is reproduced. The exposure necessary to copy an autochrome is about two hours of direct sunshine, or several hours of good diffused light and one hour of sunshine to finish it. Coloured light-filters are supplied, and one or both of them are placed over the frame during the exposure. They serve to absorb the ultra-violet and adjust the comparative colour intensities. The paper after exposure is desensitised, or "fixed," and the prints may then be kept in a feebly-lighted room for a considerable time without obvious change; and in the dark, as in an album, they may be regarded as practically permanent.

THE INSTITUTE OF METALS. — The London meeting of the Institute of Metals will be held at the Institution of Mechanical Engineers, Storey's Gate, Westminster, S.W., on Tuesday, January 16th, and Wednesday, January 17th, 1912. The meeting will commence on Tuesday afternoon, when the President-Designate (Professor W. Gowland, F.R.S.) will deliver his inaugural address on the subject of "Copper and its Alloys in Early Times." Wednesday, January 17th, will be devoted to the reading and discussion of papers,

Hosted by Google

amongst which may be mentioned the following:—"Properties of Certain Copper Alloys at High Temperatures," by G. D. Bengough, M.A.; "Further Experiments on the Inversion at 470° C. in Copper-Zinc Alloys," by Professor H. C. H. Carpenter, M.A., Ph.D.; "The Influence of Oxygen on Copper containing Arsenic or Antimony," by R. H. Greaves; "The Nomenclature of Alloys," by Dr. W. Rosenhain, B.A.; "Poisoned Brass, and its Behaviour when Heated in Vacuo," by Professor T. Turner, M.Sc.; and a paper by Dr. Carl Benedicks, of the University of Stockholm, dealing with some novel experimente on a zinc-antimony alloy.

International Congress of Applied Chemistry.—The eighth International Congress of Applied Chemistry will be held from September 4th to 12th, 1912. The opening meeting will take place at Washington, and the other meetings, business and scientific, at New York. The Congress will be opened by the President of the United States. An invitation has been issued by the officers and members of the executive committee to members of the Royal Society of Arts to attend the Congress, and those desiring further particulars should apply to Dr. Bernhard C. Hesse, Secretary of the Congress, 25, Broad Street, New York.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings, at 8 o'clock:—

November 29.—A. E. Berriman, "The Efficiency of the Aeroplane." Dugald Clerk, F.R.S., will preside.

December 6.—J. A. J. de Villiers, "British Guiana and its Founder, Storm Van 's Gravesande." Lord Reay, G.C.S.I., G.C.I.E., LL.D., will preside.

December 13.—W. Yorath Lewis, M.Am. Soc.M.E., A.M.I.Mech.E., Assoc.M.I.E.E., "Continuous Service in Passenger Transportation."

Indian Section.

Thursday afternoon, at 4.30 o'clock:—

December 14.—J. Travers Jenkins, Ph.D., D.Sc., Superintendent of the Lancashire and Western Sea Fisheries, "Fisheries of Bengal." Sir Steuart Colvin Bayley, G.C.S.I., C.I.E., will preside.

Cantor Lectures.

Monday evenings, at 8 o'clock:—

Professor Vivian B. Lewes, "The Carbonisation of Coal." Four Lectures.

Syllabus.

Lecture I.—November 27.—*The Composition of Coal.*—Existing theories on the composition of coal and the chemistry of its formation—Humus and resin compounds found in lignites, and the action of heat upon them—The classification of coals, and the effect of composition on the products of decomposition by heat—Coking and non-coking coals.

Lecture II.—December 4.—*The Methods Employed in the Destructive Distillation of Coal.*—The changes which have taken place during the last century in the forms and settings of gas retorts—The developments of the last ten years and present position of the gas industry—The coke industry and the gradual development of the modern recovery plant—The influence of the retort or oven on the carbonisation.

Lecture III.—December 11.—*The Thermal Conditions existing during the Carbonisation of Coal.*—The heat of formation of coal—The work of Euchene, Mahler, and others—The cause of the endothermic nature of some coals—The thermal value of the reactions taking place in the retort—The losses of heat in a retort setting—The transmission of heat through the retort and charge—The effect of temperature and travel on the primary products of decomposition—The temperatures existing in retorts and ovens—Small charges and full charges—The influences which lead to improvement in the products from full charges, chamber and vertical retorts.

Lecture IV.—December 18.—*The Possible Improvements in Carbonisation.*—The aims of the gas manager and coke producer—Experiments on low temperature distillation and their teaching—The rivalry existing between fully-charged retorts, vertical retorts, recovery ovens, and chamber carbonisation—The intermittent vertical retort *versus* the continuous vertical systems—The Settle-Padfield, Duckham-Woodall, and Glover-West processes—The ideals of carbonisation—The volume of gas due to primary and secondary reactions—The gasification of tar—The limitations of volume and quality of gas—The ends to keep in view in devising new processes of carbonisation.

Papers to be read after Christmas:—

Cecil Thomas, "Gem Engraving."

F. Martin Duncan, "The Work of the Marine Biological Association."

H. A. Roberts, M.A., "The Relations of Science to Commerce and Industry."

John Nisbet, D.Oec., late Conservator of Forests, Burma, "The World's Decreasing Timber Supplies."

Frank Warner, "Silk."

Charles C. Allom, "The Development of Artistic Skill in the Applied Arts."

Cyril Davenport, "Illuminated MSS."

Ernest Kilburn Scott, Assoc.M.Inst.C.E., M.I.E.E., "The Manufacture of Nitrates from the Atmosphere."

Charles Bright, F.R.S.E., M.Inst.C.E., M.I.E.E., "The Administration of Imperial Telegraphs."

Hosted by Google

HAROLD COX, "The Interdependence of Morals and Economics."

PROFESSOR G. W. OSBORN HOWE, "Recent Progress in Radio-Telegraphy."

E. D. MOREL, "British Rule in Nigeria."

GORDON CRAIG, "Stage Illusion."

THEODORE E. SALVESEN, "The Whaling Industry of To-day."

LEONARD HILL, M.B., F.R.S., and MARTIN FLACK, M.A., M.B., B.Ch., "The Influence of Ozone in Ventilation."

E. A. GAIT, I.C.S., C.I.E., Census Commissioner for India, "The Indian Census of 1911."

WALTER SAISE, D.Sc., M.Inst.C.E., F.G.S., "The Coal Industry and Collier Population of Bengal."

NEVILLE PRIESTLEY, Managing Director, South Indian Railway, "Indian Railways."

W. A. LEGG, M.Inst.C.E., "Irrigation in South Africa."

ALAN BURGOYNE, M.P., "Colonial Vine Culture."

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

January 18, February 8, March 14, April 25, May 16.

COLONIAL SECTION.

Tuesday afternoons, at 4.30 o'clock:—

January 30, February 27, March 26, May 7.

CANTOR LECTURES.

Monday evenings, at 8 o'clock:—

VAUGHAN CORNISH, D.Sc., F.G.S., F.C.S., "Ocean-Waves, Sea-Beaches, and Sandbanks." Two Lectures.

January 22, 29.

LOUDON M. DOUGLAS, "The Meat Industry." Three Lectures.

February 5, 12, 19.

LUTHER HOOPER, "Hand-Loom Weaving." Three Lectures.

February 26, March 4, 11.

NOEL HEATON, F.C.S., "Materials and Methods of Decorative Painting." Three Lectures.

March 18, 25, April 1.

HOWARD LECTURES.

Monday evenings, at 8 o'clock:—

CAPTAIN H. R. SANKEY, R.E., M.Inst.C.E., "Heavy Oil Engines." Four Lectures.

April 29, May 6, 13, 20.

JUVENILE LECTURES.

Wednesday afternoons, at 5 o'clock:—

CHARLES VERNON BOYS, F.R.S., "Soap Bubbles." Two Lectures.

January 3, 10.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, NOVEMBER 27...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Professor Vivian B. Lewes, "The Carbonisation of Coal. Lecture I.—The Composition of Coal."

Surveyors, 12, Great George-street, S.W., 8 p.m. Discussion on Mr. J. J. Dones's paper, "The Development of Building Land."

Actuaries, Staples Inn Hall, Holborn, W.C., 5 p.m. Mr. G. J. Lidstone, "A New Method of Approximating to the Values of Last Survivor Annuities on two or more lives, and to the Values of Joint Life Annuities when the advantages of Makeham's Law are not available."

London Institution, Finsbury-circus, E.C., 5 p.m. Dr. A. Hill, "Man under the Microscope."

Architectural Association, 18, Tufton-street, S.W., 7.30 p.m. Mr. A. T. Bolton, "Thoughts on Jacobean Architecture."

TUESDAY, NOVEMBER 28...Sociological, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5.15 p.m. Mr. G. P. Gooch, "Histories and Historians of Civilisation."

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Mr. R. T. Smith, "Electric Lighting of Railway Trains: the Brake-Vehicle Method."

Hungarian Society, at the Galleries of the Royal Society of British Artists, Suffolk-street, S.W., 8.30 p.m. Mr. W. H. Shrubsole, "Picturesque Hungary."

Photographic, 35, Russell-square, W.C., 8 p.m. Dr. H. Roger-Smith, "Rambles around Zermatt and Arolla."

Anthropological, 50, Great Russell-street, W.C., 8.15 p.m. Captain B. T. Somerville, "Pre-historic Monuments in the Outer Hebrides and their Astronomical Significance."

Colonial, Whitehall Rooms, Whitehall-place, S.W., 4 p.m. Mrs. Mary Gaunt, "British and German Influence in West Africa."

WEDNESDAY, NOVEMBER 29...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. A. E. Berriman, "The Efficiency of the Aeroplane."

African Society, Trocadero Restaurant, Shaftesbury-avenue, W., 9 p.m. 1. Sir George Denton, "Twenty-three Years in Lagos and the Gambia." 2. Sir Henry Gallwey, "Nigeria."

United Service Institution, Whitehall, S.W., 3 p.m. Baron Roenne, "Protection for Warships against Torpedoes."

THURSDAY, NOVEMBER 30...Men of Sussex Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. E. A. Martin, "The Downs and Dew-Ponds of Sussex."

Royal, Burlington House, W., 4.30 p.m.

Antiquaries, Burlington House, W., 8.30 p.m.

London Institution, Finsbury-circus, E.C., 6 p.m. Dr. H. R. Mill, "Storm Rains."

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Mr. F. Martin Duncan, "Romance of Marine Biology."

Auctioneers, 34, Russell-square, W.C., 7.45 p.m. Mr. E. Evans, "The Finance (1909–10) Act, 1910—The Land Taxes."

FRIDAY, DECEMBER 1...British Empire Naturalists' Association, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. J. Buckland, "The Value of Birds to Man."

Engineers, Junior Institution of, at the Institution of Electrical Engineers, Victoria-embankment, W.C., 8 p.m. Mr. J. J. Lassen, "Modern Methods of Water Softening and Purification."

Civil Engineers, 25, Great George-street, S.W., 8 p.m. (Students' Meeting.) Messrs. James and Will Legg, "Brake-Lining Coefficients of Friction."

Hosted by Google

Journal of the Royal Society of Arts.

No. 3,080. VOL. LX.

FRIDAY, DECEMBER 1, 1911.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, DECEMBER 4th, 8 p.m. (Cantor Lecture.) Professor VIVIAN B. LEWES, "The Carbonisation of Coal." (Lecture II.)

WEDNESDAY, DECEMBER 6th, 8 p.m. (Ordinary Meeting.) J. A. J. DE VILLIERS, "British Guiana and its Founder—Storm van 's Gravesande." LORD REAY, G.C.S.I., G.C.I.E., LL.D., will preside.

Further details of the Society's meetings will be found at the end of this number.

CANTOR LECTURES ON "THE CARBONISATION OF COAL."

On Monday evening, November 27th, Professor VIVIAN B. LEWES delivered the first lecture of his course on "The Carbonisation of Coal."

The lectures will be published in the *Journal* during the Christmas recess.

CANTOR LECTURES ON "ROCK CRYSTAL."

The Cantor Lectures on "Rock Crystal: its Structure and Uses," by ALFRED E. H. TUTTON, M.A., D.Sc., F.R.S., have been reprinted from the *Journal*, and the pamphlets (price one shilling) can be obtained on application to the Secretary, Royal Society of Arts, John Street, Adelphi, London, W.C.

A full list of the Cantor Lectures which have been published separately, and are still on sale, can also be obtained on application to the Secretary.

JUVENILE LECTURES.

The usual short course of lectures adapted for a juvenile audience will be delivered on Wednesday afternoons, January 3rd and 10th, at 5 o'clock, by CHARLES VERNON BOYS, F.R.S., on "Soap Bubbles."

Each Member is entitled to a ticket admitting two children and an adult.

A sufficient number of tickets to fill the room will be issued to Members in the order in which applications are received.

Members who require tickets for the course are requested to apply for them at once.

INDIAN SECTION COMMITTEE.

A meeting of the Committee of the Indian Section was held on Wednesday afternoon, November 29th. Present:—

Sir William Lee-Warner, G.C.S.I. (Chairman of the Committee), Sir M. M. Bhownaggree, K.C.I.E., Sir George Birdwood, K.C.I.E., C.S.I., LL.D., M.D., William Coldstream, B.A., Sir Steyning William Edgerley, K.C.V.O., C.I.E., Sir Frederic W. R. Fryer, K.C.S.I., Colonel Sir Thomas Hungerford Holdich, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc., Sir James Digges La Touche, K.C.S.I., Henry Luttman-Johnson, R. A. Leslie Moore, Sir Patrick Playfair, C.I.E., Sir James Wilson, K.C.S.I., Colonel Charles Edward Yate, C.S.I., C.M.G., M.P., with S. Digby, C.I.E. (Secretary of the Section), and G. K. Menzies, M.A. (Assistant Secretary of the Society).

PROCEEDINGS OF THE SOCIETY.

THIRD ORDINARY MEETING.

Wednesday, November 29th, 1911; DUGALD CLERK, F.R.S., M.Inst.C.E., Member of the Council, in the chair.

The following candidates were proposed for election as members of the Society:—

Costello, John Francis, B.A., Camp, Sholapur, Deccan, India.

de Villamil, Lieut.-Colonel Richard, Carlisle Lodge, Rickmansworth.

Foord, Charlton Willoughby Hougham, 23, Kitson-road, Barnes, S.W.

Hosted by Google

Harrop, Edwin, 109–119, Rosebery-avenue, E.C.

Heath, Dudley, Pembroke Lodge, Winchmore-hill, N.

Huntsman, Henry William Tite, Rions, Northwick Park-road, Harrow, Middlesex.

Morgan, George, I.S.O., Downings, Wallington, Surrey.

Stout, Arthur Purdy, 574, Madison-avenue, New York City, U.S.A.

The following candidates were balloted for and duly elected members of the Society:—

Angel, Robert John, M.Inst.C.E., A.R.I.B.A., Town Hall, Spa-road, S.E.

Baildon, Arthur Edward, Yeo Cottage, 6, Yeo-street, Yeoville, Johannesburg, South Africa.

Bain, Professor Samuel M., University of Tennessee, Knoxville, Tennessee, U.S.A.

Banganapalle, The Nawab of (Nawab Saiyid Ghulam Ali Khan Bahadur), Banganapalle, India.

Beanes, Fred. E. V., 4, Morden-road, Blackheath, S.E.

Benson, His Honour Judge William Denman, 10, William-street, Lowndes-square, S.W.

Bhattacharya, Professor Saratchandra, M.A., F.C.S., St. Columba's College, Hazaribagh, Bengal, India.

Black, Professor Ebenezer Charles, LL.D., 50, Kirkland-street, Boston, Mass., U.S.A.

Bray, Henry Freer, 12, Shinryudo-cho, Azabu, Tokyo, Japan.

Bremner, Alexander, 38, New Broad-street, E.C.

Bright, Alfred Ernest, 34, Queen-street, Melbourne, Australia.

Burnside, William, Assoc.M.Inst.C.E., c/o Messrs. MacBride, McGrouther & Co., 149, West George-street, Glasgow.

Butcher, Miss Anna Deane, c/o Dr. Bailey, Featherstone Hall, Southall, Middlesex.

Canjee, Sheriff D., 13, Cuffe-parade, Bombay, India.

Cantlie, James, M.A., M.B., F.R.C.S., D.P.H., 140, Harley-street, W.

Chowdhury, Brajendra Kishore Roy, Gouripore, Mymensingh, India.

Clare, George Herbert, P.O. Box 1194, Saskatoon, Saskatchewan, Canada.

Cocks, Robert Macfarlane, 24, Oakwood-court Kensington, W.

Coen, Giorgio Silvio, San Polo, Palasso Bernardo 1978, Venice, Italy.

Cole, Harold Linter, c/o Messrs. King, King & Co., Bombay, India.

Corfe, Right Rev. Bishop Charles John, D.D., Church House, Dean's Yard, Westminster, S.W.

Cross, Malcolm, 1, Devonshire-gardens, Glasgow, W., and Carlton House, 11D, Regent-street, W.

Daniel, Captain F., Penang Pilot Association, Government Buildings, Penang, Straits Settlements.

Datta, Aswini Kumar, Barisal, Eastern Bengal and Assam, India.

Dickson, Charles Allan, Kadarma, E.I.R., India.

Douglas, Greville, 27, Wilton-crescent, S.W.

Dukoff-Gordon, Ronald, B.A., Germiston, Transvaal, South Africa.

Dutt, Ajit Kumar, Dilkusha, Bhowanipore, Calcutta, India.

Edgley, Sydney William, F.C.P.A., 20, St. George's House, 73, St. George's-street, Cape Town, and Rosebank, Cape Town, South Africa.

Ellahie, Abdur Raheen Buksh, 10, Colootolah-street, Calcutta, India.

Elliott, Dawson K., 35, Kennedy-street, Winnipeg, Manitoba, Canada.

Fitz-Gibbon, William Guerin, B.A., The China Mutual Life Assurance Co., Limited, Hangchow City, Chekiang Province, China.

Fletcher, A. Byers, D.D.S., 9, Park Mansions, Knightsbridge, S.W.

Gee, William John, 48, Kingsmead-road, Tulse-hill, S.W.

Gupte, Rai Bahadur B.A., F.Z.S., Indian Museum, Calcutta, India.

Hajime, Councillor Hodo, Kiobashi, Tokyo, Japan.

Hamilton, Professor George Hall, B.A., 12, Grove End-road, St. John's-wood, N.W.; and Bellevue College, Bellevue, Nebraska, U.S.A.

Hate, Professor Vinayak Nanabhai, B.Sc., Girgaon Back-road, Girgaon, Bombay, India.

Hewlett, William George, Box 3492, Johannesburg, South Africa.

Jackson, B. Leslie, A.R.C.A., Croft Lodge, The Park, Newark-on-Trent.

Jameson, Percy R., Taylor Instrument Company, Rochester, New York, U.S.A.

Jhaveri, Krishnalal Mohanlal, Girgaon Post Office, Bombay, India.

Lloyd, Charles Sidney FitzRoy, Custom House, Shanghai, China.

MacMahon, Major Percy Alexander, R.A., Sc.D., LL.D., F.R.S., 27, Evelyn Mansions, Carlisle-place, S.W.

McMorran, Thomas, 101, Leadenhall-street, E.C.

Martini, Dr. Erich, Wiesbadenerstrasse, 5, Friedenau, Berlin W., Germany.

Mawson, C. O. Sylvester, P.O. Box 886, Springfield, Mass., U.S.A.

Meyer, Ralph A., B.Sc., Box 92, South Porcupine, Ontario, Canada.

Misra, Syama Behari, B.A., Jodhpur, India.

Monsbourgh, Alan G., A.R.I.B.A.; Sauers Buildings, Market and Loveday Streets, Johannesburg, South Africa.

Morley, Geoffrey Hope, 2, Grosvenor-square, W.

Morrill, George Pillsbury, Ph.B., M.Am.Soc.C.E., Sagua la Grande, Cuba.

Mottram, Arthur H., Tin Areas of Nigeria Co., Limited, P.O. Naraguta, Bauchi, N. Nigeria, West Africa.

Munson, Professor John P., M.D., 706, North Anderson-street, Ellensburg, Washington, U.S.A.

Nilambur, The Raja of, Nilambur, Malabar, India.

Pierret, Christian, 39, Lombard-street, E.C.

Pillai, P. Kesava Pillai Padmanabha, Trivandrum, Travancore, India.

Ram, Rai Bahadur T. Chaju, Dhar State, Central India.

Hosted by Google

Rivaz, Sir Charles Montgomery, K.C.S.I., 41, Hill-street, Berkeley-square, W.
Scott, G. Hall, M.Inst.C.E., Royal Societies Club, St. James's-street, S.W.
Seaman, Major Louis Livingstone, M.D., 247, Fifth-avenue, New York City, U.S.A.
Singer, Paul, 22, Rue Richer, Paris, France.
Standen, Bertram Prior, C.I.E., I.C.S., The Holt, Chorley Wood, Herts, and Nagpur, Central Provinces, India.
Stewart, Arthur James, 41-45, Mutual Buildings, Johannesburg, South Africa.
Stikeman, Hon. William R., Messrs. Gillanders, Arbuthnot & Co., Rangoon, Burma.
Svamin, Sriman Alkondavilli Govindacharya, C.E., M.R.A.S., 1050 (Veda-Griham), Viceroy-road, Mysore City, India.

White, Henry E., Dunedin, New Zealand.
Yule, Robert Andrew Alexander, Braeside, Fountain-road, Dulwich Wood Park, S.E.

The paper read was—

AEROPLANE EFFICIENCY.

By Algernon E. Berriman, M.Inst.A.E.,
Technical Editor of *Flight*.

Efficiency in an aeroplane, as in any other machine, is the determining factor in its capacity to do big work on a limited supply of fuel. Long journeys and flights of extended duration are limited by this, quite apart from any consideration as to the stability of the machine, the skill of the pilot, or the behaviour of the weather.

From land to land across the Atlantic Ocean, the shortest distance is some 1,700 miles, which would occupy about twenty-eight hours on a machine averaging 60 miles an hour. Fuel is being consumed during the whole of this time at a minimum rate of ·65 pints of petrol per horse-power hour, whence at least (28 × ·65 = 18·2) pints would be needed for every horse-power developed by the engine employed. This quantity would weigh, for petrol of ·7 specific gravity, approximately 15 lbs.

In flight an engine works at full power all the time, so there is no discount on the above figure when it is multiplied by the power of the engine in order to obtain the total quantity of fuel consumed.

The engine itself would weigh at least 3 lbs. per horse-power, whence the power-plant alone represents (15 + 3 = 18 lbs.) per horse-power as a minimum for the journey. The engine that would carry itself across the Atlantic must, therefore, be capable of supporting 18 lbs., in flight at 60 miles per hour, per horse-power developed.

One horse-power is equivalent to 6·3 lbs. thrust at 60 miles per hour, and the ratio 6·3 to 18 = ·35, represents the minimum thrust-lift ratio, "efficiency," or, as I prefer to call it, "coefficient of flight," for this imaginary system in which the power-plant is supposed to be flying without wings or propeller.

Directly the aeroplane and pilot are introduced into the calculation, this minimum value is altered considerably, for however light you may conceive it possible to build a machine, the man, at any rate, will weigh 150 lbs. if he is a normal specimen of humanity. This weight and the weight of the machine are fixed quantities, and their influence on the efficiency factor is greater the smaller the engine, for the more powerful the motor the less per horse-power is the increment that they represent.

For example, suppose the aeroplane and the pilot weigh 1,000 lbs. while the engine is 100 horse-power; their increment represents 10 lbs. per horse-power to the absolute minimum of 18 lbs. per horse-power in flight at 60 miles per hour, and thereby alters the coefficient of flight to ·225.

Alternatively, if only 50 horse-power is employed, the efficiency ratio is raised to 38 lbs. per horse-power, which is equivalent to a coefficient of flight of ·166. Thus, the less powerful the engine the more efficient must be the aeroplane as a whole, consequently *the chances* of building a machine that will do the job *increase with the power* of the engine, provided always that such an engine is itself as economical and light per horse-power as one of lower power.

The extra total weight of fuel required for the larger engine only affects the question in so far as it may adversely influence the design of the aeroplane proper, on which, of course, it must be carried. So far as it represents dead weight, it is proportional to the power developed, and, therefore, it is immaterial whether there is much of it or little.

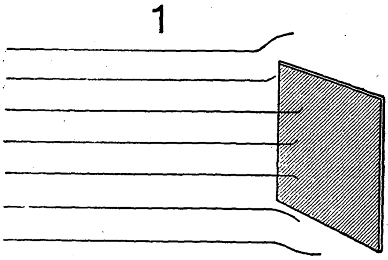
If there is a difference in fuel economy between one engine and another, the length of the journey determines whether this difference is important or not, for the effective difference in weight per

Hosted by Google

horse-power brought about thereby is ascertained by multiplying the difference in the rate of fuel consumption by *time.*

If, on the other hand, the difference between two engines is solely one of weight per horse-power, then the effective importance is unin-

1



NORMAL PRESSURE
$=\cdot 003\,V^2$

fluenced by the nature of the flight. Also it is generally small by comparison with the increment represented by the weight of the aeroplane and pilot, as explained above. For example, if the engine weighed 4 lbs. per horse-power, instead of 3 lbs. per horse-power, this would only mean a difference of 1 lb. per horse-power, whereas the aeroplane and pilot represent an increment of at least 5 lbs. per horse-power with a 100 horse-power engine.

For the sake of argument, let us assume that the engine develops 100 horse-power and works under the above conditions. It will require ($100 \times 15 = 1{,}500$) lbs. of fuel for the journey. This quantity of petrol would occupy (at 43·4 lbs. per cubic foot) nearly 35 cubic feet, and could be carried in a cylindrical tank 2·5 ft. in diameter by 7 ft. long. This investigation is important; it shows whether it is practicable to carry the initial quantity of fuel that must be put on board before the start of a long flight. Also it is some indication as to the strength and size of the aeroplane that would be required to carry the fuel in addition to the pilot and any other extra load.

It should interest those who have not previously studied this aspect of flight to observe that some fairly tangible conception of the problem is afforded by such a simple application of first principles in mechanics. None of the above deductions have been founded on any special knowledge of the laws of flight; it is simply and purely an armchair analysis of the fundamental situation, for all that has been done is to say what the coefficient of flight must be if a certain weight is to be sustained at a certain speed by a certain power.

As the conception of a self-supported mass in continuous horizontal motion is not elsewhere presented by any ordinary problem in mechanical science, it often happens that even the trained mind fails to appreciate this fundamental simplicity of the case. When a definite weight is known to be supported in horizontal motion at a definite speed by the exertion of an engine of definite power, then these very data themselves establish the ratio of thrust to lift, that is, the measure of an aeroplane's "efficiency," which I have otherwise expressed by the more appropriate term "coefficient of flight."

To know that a certain coefficient of flight is obtainable is one thing, to know how to obtain it is another. Investigation of this side of the question leads on to a study of resistance to motion through the air and the lift of a wing in flight.

First, as to resistance generally. This is primarily of two kinds; in one part it is due to normal pressure caused by the wind striking against the face of a flat surface (Fig. 1), in the other it is due to "skin friction" caused by the wind rubbing against the sides of a plate that is moving edge on (Fig. 2).

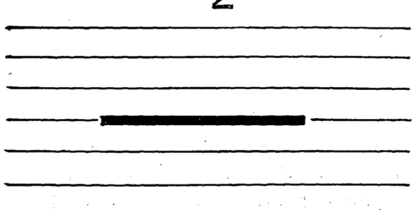
Dr. Stanton, of the National Physical Laboratory, also various other authorities, have experimentally established an accepted formula for such normal pressure resistance in the expression $R = \cdot 003V^2$, where R is in pounds per square foot of area facing the wind and V is in miles per hour.

In America, Dr. A. F. Zahm has experimentally provided a formula that has not been generally accepted, although one of the few that exist, in the expression

$$R = \cdot 0000316V^{1\cdot 85}l^{0\cdot 93}$$

(where R = resistance of double surface per foot

2



SKIN FRICTION
$=\cdot 000018\,V^2$

of span, l = chord of surface). This formula may be approximated for aeroplane wings, within the ordinary limits of modern flight speeds, by the simplified expression $R = \cdot 000018V^2$ (Fig. 3). And, as the expression itself is in doubt, there is little object in being particular as to accuracy

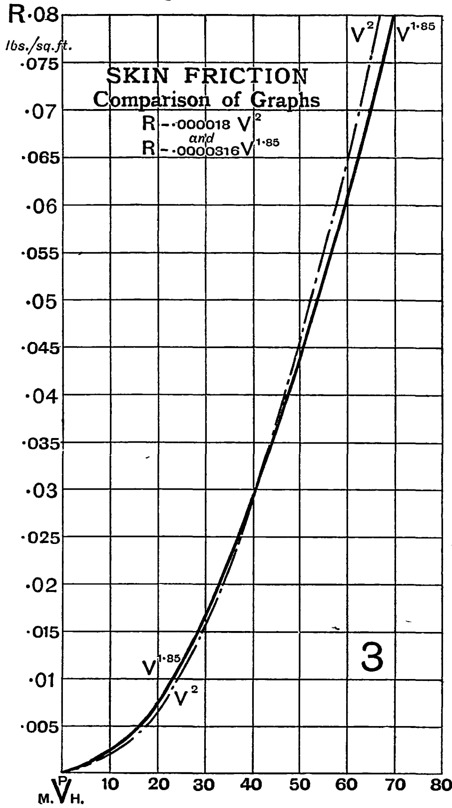
in detail at the moment. In this expression, R represents the resistance per unit of *double* surface moving as a plate edge on to the wind. When the surfaces are separated, as in the formation of a box or casing, where they would be measured separately, the coefficient in the above formula is halved to make it applicable to the single surface or external area.

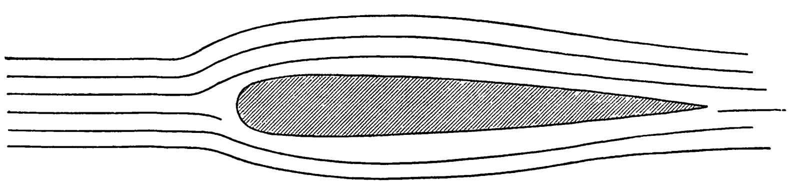
The important point to observe is that the relationship between skin friction and normal pressure is represented by the ratio of 1 to, approximately, 300. In other words, you may use 300 square feet of edge on surface to enclose 1 square foot of normal area, if you can ensure that this covering body is truly edge on in effect.

Bodies of streamline form (Fig. 4), as understood in naval architecture and in fluid dynamics generally, are supposed to convert normal pressure into skin friction; they, therefore, potentially are capable of reducing resistance within the limits indicated by the above figures. This always assumes, of course, that Zahm's coefficient is approximately representative of the true state of affairs. If it is not, then the substitution of a more accurate value will immediately show the corresponding limits of possible gain.

In any case these figures at least suggest the importance of eliminating normal pressure from aeroplane design, by the use of bodies of streamline form to enclose the larger masses on the machine.

This body resistance—in which is included the resistance of the struts, wires, and all framework except that actually forming the wings—is a resistance that is proportionate to the square of velocity (according to the above expression), and is a kind of extra dead load on the machine. It bears no relationship to the lift of the wings, and is, consequently, a detriment to efficiency. It is very important to discriminate thus between body resistance and the resistance of the wings.





4

STREAM LINE FORM

The resistance of an aeroplane wing in flight is itself of two kinds, one being the above-discussed skin friction of the surfaces, while the other is a dynamic resistance due to the creation of the aerial wave that supports the machine in flight.

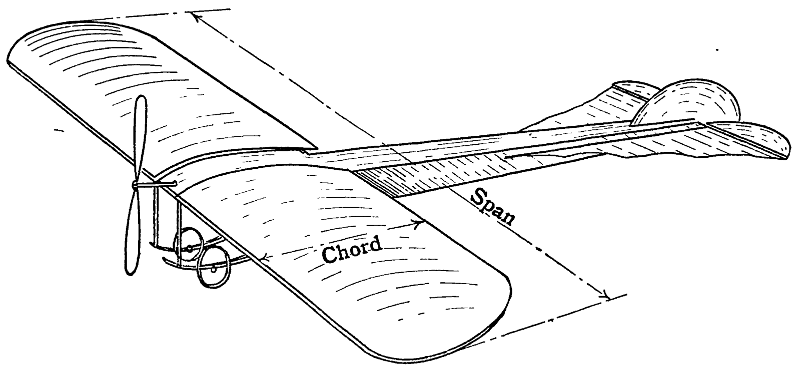
This latter we may call the resistance due to load, and it will be shown that it is a function of the effective angle of the plane. If the effective angle is reduced, the resistance due to load *per unit of supporting area* will be decreased, but in order to support the same total load the area itself must be increased, which in turn increases the resistance due to skin friction.

Hence there is a relationship between the two kinds of resistance experienced by a wing in flight, which is why the wing needs to be considered separately, and why it is not proper to include the wing surface with the body surface

Hosted by Google

when calculating the skin friction resistance of the machine as a whole.

If Zahm's expression for skin friction is accepted, we may pass on to consider the resistance due to load. It is more convenient, as an intermediate step, first to find an expression for the lifting power itself.

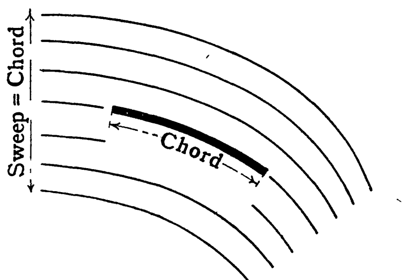


5

On the hypothesis that an aeroplane is supported in flight by the inertia of the air, it becomes possible to apply the fundamental equation $P = mf$ (where P = lifting force and m is the mass under acceleration f).

In order to apply this fundamental formula, it is necessary to find plausible expressions for the mass of air simultaneously disturbed by the wing in flight, and also an expression for the acceleration induced in that mass.

As to the mass itself, it is obviously limited in two dimensions by the span and chord of the wing (Fig. 5). Its third dimension, which corresponds to the depth of the stratum disturbed, is supposed to be a function of the chord (Fig. 6), and to have a coefficient in the order of unity. Whence we may write mass in the form ($\rho L l l = \rho A l$), (where ρ = density, A = wing area, L = span, and l = chord).



6

Next comes the question of acceleration, which, from the very nature of the function of a wing, is determined by flight velocity and angle.

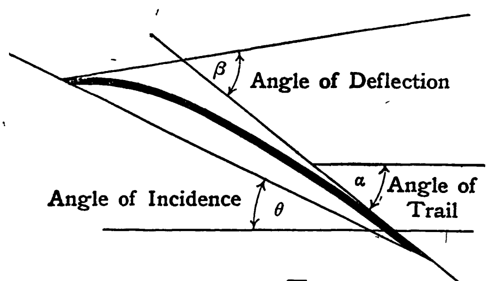
What is the effective angle of a wing?

Some say θ, the angle of incidence, some believe in the angle of trail α, but I submit that the angle of deflection β is the most plausible measurement (Fig. 7). It is immaterial, however, what angle is taken if the assumption be that the air stratum itself is deflected to the assumed degree.

Assuming that the angle of deflection as defined in Fig. 7 correctly represents the actual deflection of the air stratum, and that the camber of the wing is such as to produce uniform downward acceleration in each air molecule, then the final downward velocity with which a molecule leaves the trailing edge is represented by the expression ($V \tan \beta$) and the rate of acceleration itself by the expression

$$\left\{(V \tan \beta) \div \frac{l}{V}\right\} = (V^2 \tan \beta / l) \text{ (where V = feet per second).}$$

Thus, we have established plausible expressions for mass and acceleration, and their product should give a value for the lift or upward force of the wing in flight. Combining these expressions in multiplication, it will first be observed that the chord factor (l) cancels out of the expression, and since the area factor (A) may be removed by working in units of a square foot, or other convenient measure, we are left with



7

an expression in the order of (ρ $V^2 \tan \beta$). This, put into practical units for $\left(\frac{\rho}{g} = \frac{1}{400}\right)$ and (V = miles per hour), evolves the following definite formula for the lift of an aeroplane wing in flight
$$\frac{P}{\beta} = \frac{V^2 \tan \beta}{200}.$$

The graph of this expression is given in Fig. 8.

The next step is to find an expression for the resistance due to load, which involves the assumption that this resistance is confined to the apparent energy in the deflected air stratum. Energy is represented by the fundamental expression ($\frac{1}{2}mv^2$), and we have already evolved expressions for mass (m) and downward velocity (v).

Of these: $m = \frac{\rho}{g} Al = \frac{Al}{400}$,

and $v = V \tan \beta$,

whence $\frac{1}{2}mv^2 = \frac{V^2 \tan^2 \beta l}{800}$ foot lbs. per square foot of wing area.

Now this energy per square foot is dissipated $\left(\frac{V}{l}\right)$ times per second; hence the power expended on load may be expressed

$\frac{V^3 \tan^2 \beta l}{800 l}$ foot lbs. per second per square foot, which may be converted to resistance by dividing by (V); whence, resistance due to load is $\left(\frac{V^2 \tan^2 \beta}{400}\right)$ lbs. per square foot. (V is in miles per hour.)

The other part of the resistance to the flight of the wing is skin friction
$$R = \cdot000018 V^2,$$
whence the total resistance $= \left(\frac{V^2(\cdot000018 + \tan^2 \beta)}{400}\right)$.

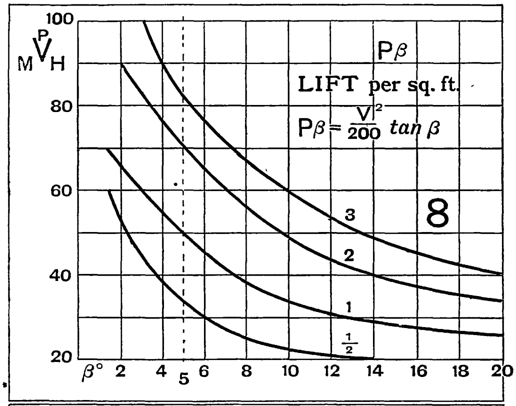
Having evolved expressions for lift and resistance, their ratio gives the coefficient of flight for the wings alone. Thus
$$V^2 \left(\frac{\tan^2 \beta}{400} + \cdot000018\right)\left(\frac{200}{V^2 \tan \beta}\right)$$
$$= \left(\frac{\tan^2 \beta + \cdot0072}{2 \tan \beta}\right).$$

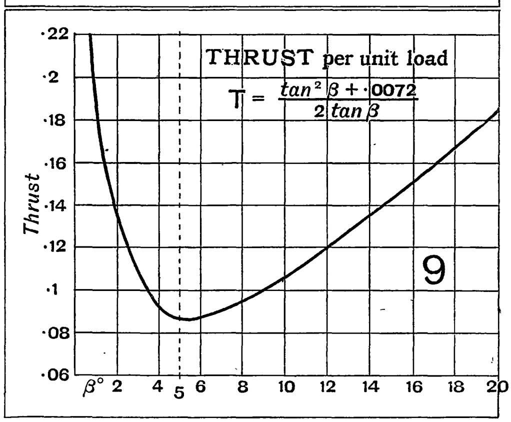
The graph of this expression is given in Fig. 9.

Now, what do these graphs show? That illustrating the coefficient of flight is particularly interesting, for it indicates that coefficient varies with the angle of the plane, is independent of velocity, and has a minimum value in the order of $\cdot085$ for an angle of deflection of 5°.

These numerical values result from the assumed coefficient for skin friction and the density of the air; the principle of an angle of least resistance to flight is unaffected by their variation. That the coefficient is independent of velocity is due to the absolute resistance and the absolute lift of a wing both being proportional to V^2. If the speed is doubled, the lift is quadrupled, and so is the resistance; their ratio is unchanged. It follows, therefore, that the most efficient variable speed machine is one having a variable area and not a variable angle. Also, that for a fixed area and weight there is a natural flight speed.

Since speed does not affect the coefficient, it follows that, from the point of view of the *wings alone*, the speed should be suited to the use of an angle of least resistance. In the graph, a very flat camber is indicated, which





implies a very high flight velocity to attain the loading that is common practice to-day. It is in respect to the very heavy loading (weight supported per unit area) of their wings that aeroplanes differ from birds, which have proportionately far larger wings.

In the construction of monoplane wings, larger areas imply greater spans and involve the use of more constructional material per unit of area in order to maintain the same strength. Thus, the net lift of the wing per unit of area diminishes in larger sizes, thereby involving

Hosted by Google

proportionately higher speed for the same loading; whence there are good grounds for the general impression that a monoplane is naturally a fast type of machine. Equally, it explains the *raison d'être* of the biplane, which is the type for efficiency at slow flight speeds.

From the point of view of body resistance, a very high flight velocity is wasteful of power, but the magnitude of the loss depends on the efficacy of streamline bodies to reduce resistance. In practice, cambers representing far higher angles than that indicated as possessing least resistance are used, in order that machines of small area may rise at moderate speeds.

So, the significance of efficiency as a governing factor in long distance flights has been discussed, and a method of mathematical analysis has been suggested. This latter, I wish to say, is intended primarily as an elementary line of thought for students, analogous to presenting the problem of the steam-engine in the time-worn formula (PLAN/33000). It does not pretend to be either scientifically complete, nor is it based on practice. It is just a skeleton framework of theory intended to help those who have the concrete bricks of fact to make most use of them in building the houses of experience wherein a practical science can only abide.

DISCUSSION.

THE CHAIRMAN (Mr. Dugald Clerk), in opening the discussion said the audience had had the pleasure of listening with much interest to a most valuable paper. He was in hopes that the author would have stated whether it was probable that a flight would be made across the Atlantic at an early date, but Mr. Berriman had evidently remembered the fate of Dr. Lardner, who, in the early days of steam navigation, made a calculation as to the possibility of a steamship crossing the Atlantic, and came to the definite result that it could not. The author had not stated whether in his opinion a flying machine could cross the Atlantic, but from the various figures that had been given, he (the Chairman) gathered that at the present moment it looked rather hopeless. In dealing with the early history of aeronautics, the author very rightly mentioned Lilienthal and Pilcher, who were both killed, but there were several British investigators whose names he did not mention. For instance, there was Sir Hiram Maxim, who put a flying machine on rails and drove it with a light steam engine. The apparatus lifted itself from the rails, but Sir Hiram never obtained sufficient command of it to venture to fly in the air. Then there was Mr. Phillips, who made a great many experiments near London a good many years ago with an apparatus running round a sort of rail from a central post, the apparatus being driven by a steam engine and fitted with a screw propeller. It had a curious sort of wing arrangement, with a number of inclined slats not very much unlike the one the author had shown, and the apparatus was driven round the circle until it rose. A much more distinguished man, Sir Charles Parsons—who was presented with the Albert medal of the Society for his invention of the steam turbine—was very much interested in aeroplanes, and about fifteen years ago made a small steam aeroplane, alcohol being used for the fuel. The little machine, which was about five feet over the wings, did fly, but as no one was on board it very soon came in contact with the trees and fell. He had a photograph at home taken by Mr. Campbell Swinton showing the machine in the air. Previous to the investigations of Chanute and the brothers Wright in America, Professor Langley carried out a large number of experiments, his chief means of experiment being a steam aeroplane on rails upon a large barge floating in a lake. When the engine started, the aeroplane shot out from the top of the barge and flew over the lake, and Langley mentions an experiment in which the machine travelled for a mile or more. Langley died before his work bore fruit, but he determined a great many important facts; and a vast amount of the data on which modern aeroplanes were designed were tabulated for the first time by Professor Langley. One very interesting remark made by the author was that at present the engine must be kept going at its full power for the whole of the time the aeroplane was in the air. Langley made a series of very interesting experiments on the nature of the wind, for the purpose of ascertaining why it was that many birds were able to keep in the air for long periods of time without any flapping or motion of the wings. He came to the conclusion that it was due to the fact that the wind was not steady, but that it acted in successive impulses. It seemed a very curious idea that the bird could take energy from the fluid in which it was suspended, but that fact seemed to be undoubted. Some years ago Mr. Lanchester also made a most interesting experiment. He took a long piece of wood with three or four inclined steps in it, made a groove running along the steps and then put a handle at the end. If a ball was put on the lower plane, by manipulating the sliding part it was possible to cause the ball to rise up first one step and then another. That was quite possible, notwithstanding the fact that the ball was resting on the mechanism all the time, and illustrated the assertion that energy could be obtained from a fluid, although the object moved was entirely immersed in the fluid. He believed that the Wright brothers were now working upon that assumption, and the statement had recently been made that they had been able to stay in the air something like ten minutes, using the impulses of the air to keep them up. If that feature could be developed, and an aviator could depend, not on a steady breeze, but on a breeze with a series of impulses, it would be possible greatly to reduce the

Hosted by Google

time when the full power of an aeroplane was required. He was very much interested in the use the author made of the word "efficiency," which arose, he presumed, from the constant use that was made of that term in engineering. People thought, as the author had said, of something with a 100 per cent. efficiency, and then reckoned how near they could get to that efficiency. Many years ago he (the Chairman) proposed the air standard of efficiency as a method of determining what were the possible efficiencies in internal-combustion engines such as petrol engines, and that air standard of efficiency, although it was well known that the air was not the working fluid, proved most useful; it gave something to measure by. In the same way the author was using the term as something to measure by, but it seemed to him that a struggle should be made to obtain some other method of expression in order that "efficiency" might be kept to its usual meaning. It seemed to him that if an aeroplane could be thought of more as a little platform projecting bullets downwards at a certain rate, some sort of standard of efficiency would be arrived at which would convey a clearer idea of what it was. One point that struck him very forcibly was the absolute necessity for high efficiencies in the petrol engine. There seemed to be a good deal of possible improvement in that direction. So far as he had tested petrol engines, he had never seen one that gave more than about 25 per cent. brake efficiency, *i.e.*, in which 25 per cent. of the heat of the petrol was converted into B.H.P. It was quite possible to design a petrol engine that would give 35 per cent. or even 40 per cent. efficiency, and in that way it was possible to obtain a great deal better figure than the ·65 pints of petrol per horse-power hour given by the author. It was a very remarkable result that petrol engines had already attained such a high efficiency, but there was much room for improvement. He had been very much interested to hear about the reaction of electric discharge, which was quite novel to him. It seemed to be a method of obtaining very high discharge velocities and possible reaction for lifting, but it was difficult to see where the energy was to come from. It might be that energy from the engines would be better used in that way, because a very large proportion of it was used in holding up the aeroplane.

Mr. Mervyn O'Gorman thought the essence of the paper was Fig. 8, where the author dealt with the angle β. But however much he would like to try to base practical work upon the angle β, he feared it was generally impossible to do so, because such a large number of results had been published in relation to aeroplanes, in which it was not possible, except from a minute diagram at the foot of the published results to know what the angle β might have been. He alluded to the book published by Eiffel, in which a number of diagrams were published, with a complete study of the data used by the author, but without any reference to the angle β which might exist between the tangent to the leading edge, and the tangent to the trailing edge. It might accordingly be said at the present time that, until much more experimentation had been done which gave more particulars of the curves, it was quite impossible to use experimentally and practically the considerations that the author had put forward. One of his assistants at the air-craft factory, Mr. Frederick Green, had taken great pains to interest himself in Eiffel's work, and had evolved a very pretty way of stating the basis upon which an aeroplane must be designed, founded upon experiments in which, unfortunately, the author's angles were not to be found. Had the original aerofoils used by Eiffel for his researches been worked out in the manner suggested a little time ago by himself, namely, by some equation being given for the curve, that difficulty would not have occurred. He was personally jeered at a little for working out an equation to a curve which was obtained simply by bending a piece of wood; but if one wished to put a record on paper, far the best way of fixing for all time an elaborate shape was to get an equation for it, so that anybody in the future could replot it and secure all the data of the curves. He hoped writers would, in future, give the equations to their curves, and when that was done he (Mr. O'Gorman) would very much like to take the author's angle β from the aerofoils and see what results could be obtained. With the Chairman, he was very much opposed to the author's use of the word "efficiency." "Excellence," or any other useful adjective which enabled one to realise that something nice was being obtained, was a better word. He thought it might be interesting to show in a very brief form how the results of Eiffel could be used in practice by means of Mr. Green's plan. (Mr. O'Gorman proceeded to describe, by means of several sketches on the blackboard, the plan evolved by Mr. Green for dealing with the question.)

Lieut.-Colonel R. de Villamil asked the author to describe how the centre of pressure in an aeroplane shifted, and for what reason.

Mr. A. R. Low thought that the curves which Mr. O'Gorman had described as due to the work of Green, bore a very strong resemblance to results obtained by Soreau, which were published in 1903, and were, therefore, prior in point of date to those of Green. With regard to the question on the movement of the centre of pressure, he agreed with Mr. O'Gorman that Eiffel's published results on the resistance of air and on the properties of various bodies constituted a source of wealth which it would take many years to exhaust. Eiffel established with the utmost clearness what had already been established with less assurance, that if a current of air was applied to a plane surface then, as the inclination was decreased, the centre of pressure originally in the middle of the plate shifted forward. That was a most important

Hosted by Google

result from the point of view of the stability of the flat plane, because as the nose went down the force pushing it up shifted further forward and obviously tended to push it back into its proper position. On a curved surface, however, those results were altered in a most striking way. (Mr. Low illustrated his argument by means of several sketches.) Continuing, he said the Wright brothers were well aware of the natural tendency of a curved surface to instability, and balanced it by an extraordinary piece of "acrobatism" by putting a comparatively small elevator right out in front; and they must have been almost as skilful as acrobats to fly time after time in light winds without breaking their necks. On the other hand, the French designers built a tail far out behind the curved surface, which would more than account for any shift of pressure. Like the Chairman and Mr. O'Gorman, he disliked the use of the word "efficiency," and suggested that the French word "quality" of the surface should be adopted. The word efficiency was now used for the ratio of work put into a machine compared with the ratio of work taken out. He also wished to suggest that the division of resistance into normal pressure and skin pressure was not complete. (Mr. Low further illustrated his contention by means of sketches on the blackboard.) In conclusion, he said that it was very easy to plot curves, but Mr. O'Gorman would find it very difficult to reproduce them permanently in canvas and wood.

Mr. A. E. Berriman, in reply, said that the various speakers had endeavonred to put a practical aspect on the paper, which was exactly the object he had in view in writing it. In reply to the criticisms which had been advanced against the use of the word "efficiency," it would be remembered that personally he had said that he preferred to use the term "co-efficient of flight." Mr. O'Gorman had shown a curve for the horse-power required. The fact that wing quality was independent of speed meant that the horse-power required to propel the wings through the air was purely a function of speed. A straight line could, therefore, be drawn representing the horse-power required; but when the body resistance was taken into consideration a V^2 law applied. There was a certain value which represented a fairly efficient angle, but on either side there was a considerable inefficiency. (Mr. Berriman proceeded to illustrate his remarks by means of sketches dealing with this particular point and also the question of normal pressure and the question of travel of centre of pressure.) As far as he understood it, the reason for the change in travel of the centre of pressure was due to the wind getting hold of the top of the downturned front edge of the wing. There was in the first instance a slightly upward trend in the wind, which was the reason that wings flew with a downturned front edge, *i.e.*, when in horizontal attitude. He regretted that he had not referred to Langley's work. Langley's work on aeroplanes was on the point of being successful, and to his mind it could have been made successful within a few months of the time that the Wrights achieved their first famous flight. It was sometimes thought that Langley's work was very much earlier than that of the Wright brothers. It was so in some respects, but the final failure took place only a few months before the Wright brothers made their first mechanical flight. Had Langley been successful, his name would have gone down to posterity with the same prominence as that of the Wright brothers. Some of Langley's work on skin friction was exceedingly interesting. He was one of the people who did not believe in skin friction at all; in other words, he would have said, as far as he (the author) understood his work, that that particular factor should be left out altogether. As far as he could understand, Langley made his experiments on a whirling table, and he used little flat planes which he described as thin sheets of wood in aluminium frames. Personally he had the impression that those planes were uncommonly heavy for experimental work. That particular line of thought indicated that when a very heavy loading existed it was necessary to fly extraordinarily fast for the angle to become flat enough to reach maximum efficiency. Langley mounted his planes on a whirling table and made them go faster and faster, and found that the skin friction on the planes was negligible compared with the resistance to load. Had Langley been able to run his machine fast enough he would ultimately, according to theory, have arrived at a point where the skin friction and the resistance of load would be equal to one another; and if he had pushed the speed further and further he would have found that the skin friction would have increased in actual magnitude beyond the resistance load; and he would not have said, as he did say, that the skin friction was a negligible quantity as a law. Practically what Langley said was, that the faster one flew the less power was required, which would have made flying to America a matter of comparative simplicity.

On the motion of the Chairman a hearty vote of thanks was accorded to Mr. Berriman for his interesting paper, and the meeting terminated.

FLORENCE AND ITALIAN DEVELOPMENT.

Some interesting facts regarding economic progress in Italy are recorded in Major Percy Chapman's report for 1910 on the trade and commerce of Florence and the large consular district appertaining to it. From this it appears that one of the chief obstacles to freer interchange of goods throughout the kingdom of Italy is the deficiency of double railway lines, and the consequent accumulation of goods in the different stations and depôts. As, however, under existing budget arrangements the railway authorities are only allowed to spend £600,000 per annum for that purpose, it will be quite twenty years before such

Hosted by Google

double tracks as are required urgently at the present time are laid down.

A gratifying increase in the savings of the nation is observable. In 1900 the savings amounted to £80,000,000, and in 1909 they had risen to £200,000,000. Wages in Italy also commenced to rise in 1900 and have continued to do so since, a fact which doubtless accounts to a great extent for the very large increase in the deposits. Considered with reference to population, Lombardy comes first with £7 14*s.* 5*d.* savings per head, Emilia next with £4 10*s.*, Latium third with £4 7*s.* 2*d.*, and Tuscany fourth with £4 4*s.*

In regard to woods and forests, a Bill has been laid before the Italian Parliament by which the only forestry school in Italy, which since 1869 has occupied the old convent of Vallombrosa, will be transferred to Florence and turned into a university for the science of forestry. In summer practical courses will be held in the State forests of Vallombrosa, Comaldoli, Abetone and Fodonica. The institute raised to the dignity of a university would hardly prosper at Vallombrosa, which is situated at a height of 1,000 metres above sea level, isolated from every kind of intellectual surroundings, while in Florence it will have the advantage of being in the immediate vicinity of public libraries, museums, and scientific equipment for study and research. The institute when transformed will issue degrees of Doctor in Forestry Sciences.

THE EGYPTIAN COTTON CROP.

Since the publication of an article on Egyptian cotton in this *Journal* on October 14th, 1910, some more experience has been gained by those who devote their attention to the culture of the most important crop in the country of the Nile. Attention was then drawn to the gradual deterioration of the cotton crop, which for long has held the highest place in the cotton market for quality, if not for quantity. The chief causes of the falling off of the Egyptian crop have been stated by experts to be (1) over-irrigation; (2) exhaustion of the land; (3) insufficiency of new, good seed; and (4) the gradual admixture of the crop with "Hindi" cotton, this being the name of an undesirable type of cotton with a short, weak fibre that injures the high grade of Egyptian varieties by infesting them with hybrids.

In August, 1910, a Department of Agriculture was formed at Cairo, with a suitable staff, to study and deal with questions that have up till now been referred to the Khedivial Agricultural Society. The Egyptian cotton crop of 1909–10 was very poor in quantity, and owing to the smallness of the supply prices were exorbitantly high. The market was already threatened by American enterprise, for the manufacturers of the States knew how to produce an imitation of the goods made with Egyptian cotton, which, if not so satisfactory, answered many purposes. The Egyptian crop of 1910–11 was so surprisingly good, and reached so high a figure, that harvest thanksgivings were held in Cairo churches, and the experts who continued to utter warnings were altogether in the minority.

The new Department of Agriculture had signified to the farmers and peasant cultivators that it was quite ready to offer advice with regard to selection of seed or cultivation, but the good crop of last summer gave such a feeling of security that the fellah appears to have taken even less care than usual. In the month of June a severe attack of cotton-worm, a much-dreaded insect pest, made its appearance. The Agricultural Department organised a special system of inspection, that was continued throughout the summer. Although all available means were adopted, the scourge raged throughout the summer. The only practical remedy was to kill the coming generation—not so much the already matured worm, but rather the small house that the pupa forms for itself, composed of earth and lime, and lined with a kind of silk. This is very hard, and needs breaking up in order to get at the pupa within and drown it. The loss by cotton worm this year is estimated at £5,000,000.

Simultaneously with the cotton-worm plague came the news that the United States Department of Agriculture has been developing the culture of Egyptian cotton in the United States. The only good results on a considerable scale have been obtained in the Colorado River region, where the climate and other conditions are similar to those in the Nile Valley, and are suited to the long staple Egyptian cotton. Six hundred thousand acres of good land will soon be growing Egyptian cotton in the Imperial, Yuma, Salt, and Gila Valleys. A fifth of this acreage could produce the amount of Egyptian cotton imported each year for the use of New England mills.

An invention has been perfected for the prevention of cotton-worm, a kiosk in the shape of a trap. A demonstration was given in June in a field near the Gaffaria Canal, in the presence of a number of well-known persons. The door was closed and sealed. When officially opened in the morning it was found that more than a thousand moths had been captured during the night. Numbers of eggs were also found in the kiosk, such as are laid by the cotton worm upon the leaves of the plant. Something may certainly be hoped from the invention; at the same time it will be some time before it can be placed on the market.

To regulate the use of cotton-seed, a matter in which Egyptian farmers have been very careless, the Agricultural Department issues circulars to the heads of villages and government cashiers in the provinces, detailing the manner in which carefully-selected cotton-seed will be put on sale at the markets of the Egyptian Markets Company, and the facilities to be accorded to farmers in the payment of the price of such seed. The seed is delivered in sealed sacks.

The most hopeful point in the outlook of the Egyptian cotton market is that since the arrival of Lord Kitchener at the British Agency the long-discussed plan of draining the Delta is being put

Hosted by Google

in hand. By this means the subsoil water, resulting from the irrigation, will be drained off. The enormous cost of the undertaking has prevented the Government from taking up the matter before.

A well-known Egyptian, writing to one of the native papers in Cairo last August, suggested as a remedy for the deterioration of the crop, that the whole country should be restrained from planting cotton for a year. He points out that, although the remedy is heroic, the price of cotton would rise during the years following, owing to the great yield of the crop on one hand and its superior quality on the other.

The crop of 1911–12 is likely to be unfortunate. The temperature nearly all through the summer has been rather below the normal, which was not favourable, the crop being liable to have its growth checked under these circumstances. In Upper Egypt the crop suffered from fogs and blight, and from attacks of boll-worm. As the cotton-worm appeared early it attacked chiefly the early bolls which usually give the best cotton, so that both in quality and quantity this season's crop is likely to be inferior to last year's.

In spite of the shortness of the supply, prices are lower than they have ever been. Mr. James I. Craig, M.A., F.R.S.E., Director of the Computation Office of the Survey Department, has lately published some cotton statistics. His general conclusion is that "The causes of the decrease in yield have been largely beyond the control of human agency, but this does not mean that they will be beyond human control in the future." Some of his conclusions are as follows:—"The rate of decrease is less in Upper Egypt than in Lower Egypt, but still the decrease exists there also. Part of the decrease in the general average yield for all Egypt may be accounted for by the lower average fertility of Upper Egypt; extension of cotton cultivation to poorer land in Lower Egypt may account for some of the decrease, but scarcely for all. None of these causes, however, will account for the fluctuations about the fairly steady rate of decrease. Change of rotation from one of three years to one of two years may account for some of the decrease, but scarcely for all . . . The cultivation of cotton is probably less intensive now than fifteen years ago . . . The value of the crop per head of the agricultural population has nearly doubled in fifteen years."

YIELD OF THE SUGAR-BEET IN EUROPE.

The statistics given below, based on the average production of sugar during the last five years in ten of the principal beet-growing countries of Europe, give:—

1. The yield of raw sugar per hectare and English acre of beet grown.
2. The percentage of raw sugar obtained from the crop.
3. The weight of the crop per hectare and English acre.

Germany heads the list as regards the production of sugar at the rate of 4,895 kilogrammes for each hectare (39 cwts. per acre), or nearly double that of Russia, which produced only 2,440 kilogrammes per hectare (19·4 cwts. per acre). Italy gave the best results as regards the quantity of beet grown, being at the rate of 30,340 kilogrammes per hectare (12 tons 2 cwts. per acre). On the other hand, the yield of sugar was one of the lowest. It is greatly to be regretted that Great Britain does not head, or at all events figure, in this list. Is this due to ignorance or apathy on the part of inhabitants of these islands?

Country.	Yield of Raw Sugar.		Percentage Sugar Obtained.	Weight of Crop.		
	Per Hectare. Kilogrammes.	Per Acre. Cwts.		Per Hectare. Kilogrammes.	Per Acre. Tons.	Cwts.
1. Germany	4,895	39·0	16·32	30,000	11	19
2. Sweden	4,347	34·6	14·95	29,070	11	10
3. Belgium	4,232	33·7	14·90	28,980	11	10
4. Denmark	4,191	33·3	13·97	29,990	11	19
5. Austria-Hungary . .	4,062	32·3	15·84	25,630	10	4
6. Holland	3,931	31·3	14·96	26,270	10	9
7. Italy	3,682	29·4	12·13	30,340	12	2
8. France	3,507	28·0	13·18	26,600	10	12
9. Spain	3,494	27·9	12·34	28,310	11	6
10. Russia	2,440	19·4	15·57	15,670	6	5

THE COST OF LIVING.

In a paper on "The Course of Prices at Home and Abroad, 1890–1910," recently read before the Royal Statistical Society, Mr. R. H. Hooker, in comparing prices in 1910 with those of the decade 1890–99, showed that wholesale prices had risen in this country by about 15 per cent., in Germany and the United States by about 30 per cent., and by intermediate amounts in France and Canada. Wholesale food prices in 1910 had risen by only about 6 or 8 per cent. here, and scarcely at all in France, while a rise of between 20 and 30 per cent. was shown in the other countries. The raw materials of industry had risen much more, viz., by 25 to 40 per cent. in all countries. A great contrast was shown between this country and America, where food and materials had risen by practically the same amount; while here, food-stuffs had risen very much less, although they had attracted much more public attention.

The data as to retail prices were scanty, and not very reliable. It appeared that, on the whole, since 1895 they had risen by about as much as wholesale prices, though in the United States they seemed to have lagged behind. Comparisons of the course of prices with wages, for which a few data were available for this country, France, and the United States, indicated that wages had not fallen behind prices except in the last year or two. The curve of wages was, however, always the smoother; and if it did not rise so abruptly during times of high prices, like the present, on the other hand it fell very little during times of low prices. In France, in particular, wages appeared to have risen most, relatively to prices, but the data were very far from conclusive.

Considering the causes of the present high level of prices, Mr. Hooker pointed out that they were threefold. First he showed how the increased production of gold in the early fifties had resulted in a rise of prices in the following quarter of a century, and how a diminished gold production had been accompanied by a steady fall in prices during 1875–95; and then pointed out that the enormous output of gold since then was sufficient to cause a rise of some 10 per cent. in the stocks available for currency. Secondly, he considered that we were now near the crest of one of those waves, due to increased demand for materials, especially minerals, which periodically recurred in prices, and which were generally associated with industrial prosperity. Thirdly, the price of food had risen very greatly during the past three months owing to the droughty summer in north-western Europe. The two former influences, superimposed, had resulted in very high cost of materials. The two latter were temporary, and when they had passed away prices would again be lower. But the effect of the large output of gold would probably persist for some time, and prices might be expected to oscillate around an average that was not likely to decrease at present.

The relatively great advance of food prices in the United States was due to the inability of agriculture to keep pace with the expansion of population; in England, on the other hand, the diminished supplies from the United States had been fully covered by supplies drawn from other countries, notably Argentina: hence the rise in food prices was relatively small here. Changes in tariffs were responsible for some of the differences noted between prices here and abroad.

THE SIAMESE TOBACCO INDUSTRY.

In Siam tobacco is produced most extensively in the Provinces of Petchaboon and Rajburi. The former is an inland province north of Bangkok, the latter has its easterly coast on the Gulf of Siam. In the first-named province the chief tobacco region is Petchaboon town. The leaf grown there is generally regarded as superior to that produced anywhere else in Siam. In Rajburi Province tobacco is cultivated mostly in the district of Wang Khanai, in Muang Kanburi. The tobacco of Siam is of two qualities, strong and mild. The strong quality is used both for smoking and chewing; cigarettes are made of it with lotus, banana, or betel-tree leaves as wrappers. The mild quality, manufactured usually as fine cut, is used solely for chewing with the quid of betel leaf and areca nut. The chief markets are in Bangkok, whither the tobacco is brought from the interior by boat and sold from the moorings in front of the monasteries Wat Kalya and Wat Bophit Bhimuk. Much of the tobacco is sent inland to the provinces of Korat, Chantaboon, Ayuthia, Nakon Sawan, and others. The customs reports show that certain quantities of Siamese tobacco were shipped to Cochin China and to Hong-Kong during 1910. Some is occasionally sent to Singapore and the Malay Peninsula. Most of it is consumed locally. The soils usually selected as suitable for tobacco cultivation are of three kinds, namely, bamboo forest, scrub land, and high grass land. The American Consul-General at Bangkok says that the soil that is considered the best is sandy or black and yellowish loam. In this kind of soil in Petchaboon Province tobacco can be grown on the same area successively for twenty years without the need of fertilisers, while in Rajburi it can be grown successively only for three years at the most. Nursery grounds have to be dug to about nine inches in depth and well broken, and then prepared into raised beds three feet wide. The seeds are sown broadcast on the beds, where some protection against the sun must also be provided. Transplanting takes place when the shoots are nine inches high. The actual season for transplanting differs according to the level of the land. If high it takes place about November, if low in December, and in very low-lying ground as late as January or February. The reason for this difference of the season for transplanting is the simple one that high grounds get rid of moisture the sooner. In March or April the crops are

Hosted by Google

harvested. The time chosen depends upon the colour of the leaves and the picking is upward from the lowest ones. Two or three top leaves from each plant are set aside for manufacture into a special high-class quality. If a uniform grade is required the whole plant may be shorn of its leaves indiscriminately at the same time. For maturing the gathered leaves are first ribbed and then placed on the top of each other, rolled up and put away for two days, after which they are unrolled and packed on the top of each other to a thickness of about six feet. Round pieces of wood are pressed on the top of the leaves, which are rolled into the shape of cylinders; the wooden rollers are then taken out and the leaves left to dry in the shade for about three days. They are then finely cut, well separated from impurities on large sieves, and dried in the sun for one day. If a strong quality and dark colour are desired, the sun drying may be extended to two days. At night the cut tobacco becomes soft enough for manipulation into different shapes for packing and shipment. The packing is either in bales made of large dried leaves, called "baitong ruong," or in bamboo crates.

HOME INDUSTRIES.

The Poultry and Tobacco Industries.—The Development Commissioners have been taking evidence on tobacco cultivation in Ireland and poultry development in Great Britain, and an application is about to be made to the Development Fund to establish and maintain a poultry institute in a convenient centre in England. The main object of the institute would be to investigate and demonstrate the best methods of breeding, rearing, and keeping all kinds of poultry with a view to the increased production of eggs and table poultry in this country, and the preparation and marketing of such produce. We are much behind Continental nations in agricultural education. In Belgium, for example, all primary schools in country districts give instruction in agriculture, and in some cases this is followed up by continuation classes held in the evening, and attended by children who have recently left primary schools, and are probably already engaged in country pursuits during the day. Then there are the travelling schools, where agriculture, dairying and domestic economy are taught. But the most important part of the agricultural teaching given in Belgium is directly organised by the State experts (*agronomes de l'État*), of whom there are twenty-seven with eight assistants. These *agronomes* have organised a large number of popular lectures on general farming, the feeding and management of cattle, farriery, fruit growing, market gardening, floriculture, etc. Many interesting particulars of the way in which the Belgian State authorities seek to advise and guide cultivators are given by Mr. Rowntree in his "Land and Labour Lessons from Belgium," and he says that it is instructive to accompany one of the *agronomes* to market and see how constantly he is hailed and consulted on all kinds of questions. Much service is also rendered by the experimental plots, of which there are about a hundred in Belgium under the charge of the *agronomes*. The Belgian cultivator may be more willing than the British farmer, or small holder, to accept advice and guidance from experts, but the Government might usefully do much more than it does—until very recently it did nothing—towards solving the problem of how best to further agricultural education. The enlightened policy of Belgian statesmen in this direction has had very remarkable results. Mr. Rowntree gives figures which show that, comparing the net imports, Belgium imports live stock and meat to the amount of 1*s.* 8½*d.* per head of the population per annum, against 23*s.* for the United Kingdom. She imports dairy produce (butter and cheese) to the value of 2*s.* 3*d.* per head, as compared with 12*s.* 9*d.* for the United Kingdom, and eggs to the value of 7*d.* per annum against 3*s.* for the United Kingdom. Of fruit, the United Kingdom's imports amount to 2*s.* 6*d.* per head, whereas Belgium exports fruit to the value of 1*s.* 4½*d.* per head. An equally wide difference is to be found in the case of vegetables, the United Kingdom importing 2*s.* 1*d.* worth per head, whereas Belgium exports 8*d.* worth per head. The prices of food stuffs in the two countries are very similar, nor can the differences be accounted for by the *per capita* consumption of the various articles, for though the Belgian eats less meat than the Briton he consumes more vegetables and more grain. Nor can protective tariffs solve the problem, since the difference between the two countries is as striking in the case of eggs and vegetables, which are unprotected, as of meat and dairy produce, which are protected. In Belgium the value of food imported amounts to an average of £1 18*s.* 2*d.* per head of the population per annum. In the United Kingdom the corresponding figure is £3 14*s.* 10*d.*, notwithstanding the fact that Belgium has a population of 589 persons per square mile and the United Kingdom only 342. In face of these facts and figures it is very difficult to controvert Mr. Rowntree's conclusion that agriculture in England might and should become much more intensive. The soil of Belgium, taking it as a whole, is less good than that of Britain, and the climate is no better. She does so much better partly owing to the light-railway system, and her methods of agricultural co-operation, but also, and largely, because, thanks to the efforts of the State, her farmers know how to get all that is to be got out of the soil.

The Electrification of Railways.—The electrification of railways grows apace. First came the tube railways, then the Underground, followed by the North-Eastern, and the system installed by the Brighton Company. And now the announcement is made by the London and North-Western that several important improvements are about to be carried out to enable it to enter into more effective

Hosted by Google

competition with the railways which deal with London's suburban traffic. We are almost within sight of the time when the whole of the suburban traffic on our railways will be electrically driven. If the railways are to fight the tramways and motor-cars successfully, they must do so with their own power. With the growth of manufacturing centres, and the driving further afield of desirable residential localities, rapidity of transit becomes indispensable, and the system of traction which gives a high schedule speed where stops are frequent is the one that will succeed. Assuming the maximum economical schedule speed with stations about one and a quarter miles apart to be thirty miles, and one hour as representing the maximum distance the business man is willing to live from his work, the radius of economic and remunerative suburban traffic is, approximately, thirty miles from any large town. In a paper on the electrification of railways recently read by the manager of the Lancashire and Yorkshire Railway Works at Horwich, it is said that an electric motor-car would run fifty thousand miles without visiting the shed other than for stabling, and could be kept in continuous service for twenty hours daily, the only attention required being brake adjustment. A steam locomotive on a similar service must obtain coal every hundred and fifty miles, and requires a thorough washing out and overhaul every twelve hundred miles at the least. By reason of its higher acceleration and average speed on short runs, the electric service could be increased in frequency with the same headway between trains, thus increasing the capacity of the line. Of course, the nature of a railway's mileage must have an immense influence on the choice of a system of electrification, and the single-phase system suitable for one line may not be applicable to another. And whilst the financial difficulties to be reckoned with in the electrification of suburban lines are great, it would be a stupendous task to insure a profitable return upon the capital required to electrify one of the great systems. Thus Mr. O'Brien estimates that the cost of electrifying the whole Lancashire and Yorkshire Railway system would be £5,700,000 in round figures, and to pay 4 per cent. interest on this would take £228,000 per annum, which means that if the cost of operation remained the same, and the receipts were not increased, the dividend would fall by nearly $1\frac{1}{4}$ per cent. For although certain economies might be reckoned on, certain expenses would increase; so that it would be necessary, as the result of electrification, to make certain of an immediate increase of about 5 per cent., say, £300,000, in total receipts, an increase that would have to come mainly from the suburban areas.

Fining in the Weaving Trade.—It is inevitable that a system of fining should tend to bad relations between those who exact the fines and those who have to pay them. The fining of weavers in the cotton trade has had this effect, and there are indications that it is likely to be discontinued, or at least greatly lessened, in the near future. According to a correspondent of the *Cotton Factory Times*, in one weaving centre "two or three employers have posted notices to the effect that all fines deducted from the weavers' earnings will in future be distributed equally between all the weavers employed at these mills." But this solution of the problem is not likely to commend itself to many of the opponents of fining. It does, indeed, meet the objection that employers are able to make a profit out of fines, but even weavers who have gone through the year without a fine may be disinclined to participate in any yearly distribution. The *Factory Times* says that "these Lancashire employers are giving up fining at the request of their weavers, and intend tentatively to see what the result will be at the end of six months." The abolition of fines might make the bad or middling weaver's job less secure than before, but it would make for efficiency.

The Minimum Wage for Co-operators.—Resolutions in favour of the principle of the minimum wage for all females in their employment have been passed by three successive Co-operative Congresses. These resolutions have now been followed by a report issued by the Directors of the Co-operative Wholesale Society which will be considered by delegates from Co-operative Societies all over the country at their meeting next month. The report is hostile to the proposal, chiefly on the ground of cost. The minimum scale proposed starts at 5*s*. per week at the age of fourteen, and increases to 17*s*. per week at the age of twenty. This would increase the present wage bill by £60,000 per annum. The report states that the Co-operative Wholesale Society employs 7,072 females, 5,407 of whom work forty-eight hours or less per week. Wherever the women are in a trade union the standard rate of wages demanded is paid, and where they are not the wages paid are always the highest in the district. The directors would welcome the formation of a Trade Board, under the 1909 Act, and would be pleased if its principles of a minimum wage and a maximum working day could be enforced on all employers; but, as matters are, the adoption of the minimum wage for all females would lead to employers demanding from employees corresponding standards of efficiency, and girls over a certain age would not be employed without previous experience.

Indigo Dyeing.—A special committee is about to be formed in connection with the Textile Institute to consider the question of fixing a recognised standard of indigo-blue dyes in cloth. There is an increasing quantity of goods which contain but a very small percentage of indigo-blue, and it is thought that if a standard could be established it would encourage honest trading. The Admiralty, the War Office, and the Post Office are all large purchasers of goods containing the

Hosted by Google

dyes in question, and they are much interested in the proposed inquiry. It is understood that both the Admiralty and the Board of Trade have asked to be represented on the committee.

CORRESPONDENCE.

BANKING IN THE UNITED STATES OF AMERICA.

Mr. James Douglas, in his interesting address to the Society on the 22nd November, made mention of the unpremeditated effect of the Sherman Act upon railway ownership, and showed how the prohibition contained in the Act against "combinations for restraint of trade" had, in fact, stimulated speculative enterprise in the form of combination by purchase. His further explanation (which is not included in the printed report) was that the restriction sought for by the framers of the Sherman Act was to prevent monopolies of all kinds. Under it no firm or company can make any sort of arrangements for joint running or for limit of prices, or do other such things for mutual benefit, and naturally the more ardent spirits, who have looked beyond the length of their own shadows, have soon found a wider field without for many years being overtaken by the law.

I do not remember having heard this view of the relation of the trusts and the Sherman Act expressed before, nor have I noticed any suggestions to the same effect in any recent financial papers. Now, however, that I fully appreciate the view set forth by Mr. Douglas, and amply demonstrated by circumstance, it comes upon me that another effect has been produced in another direction, which also could not have been foreshadowed in the minds of the framers of the Sherman Act.

It is evident from what Mr. Douglas said that the law as to co-operation by mutual consent has been closely guarded and respected, and apparently by none more than by the banks.

It is equally evident that the banking system, unlike most other industries in the United States, is less progressive than the systems of nearly all other civilised countries, and is, in fact, as out-of-date as an old sail windmill.

I think it may be argued that these conditions are as much the offspring of the Sherman Act as are the trusts, and the conclusion can only be that that Act was framed with more regard for sentiment than as a workable law. The banks are too much in the public eye to evade the written law, and they are now at their wits' end to see how they can keep it and break it at the same time. That is, they wish, and indeed are being forced, to co-operate for the ordinary regulation of finance, and to do so they must get a special Act passed to enable them to evade the law. But to keep true to sentiment, they propose to remain isolated units among the massed forces of industry, politics and speculation all around them, and at the same time jointly to own and manage a central institution which is to be their regulator and guide.

All this seems very inconsistent and contradictory. I should like to know whether these results are, as I suggest, traceable to the Sherman Act, and also, whether that Act prohibits, directly or indirectly, the opening of branch offices by banks in neighbouring towns, other States, and in foreign countries, and the discounting of bills drawn against goods passing from one State to another, or to a foreign country? We read occasionally of the merger of two banks in the United States. As this presumbably cannot mean an amalgamation such as we have in England, does it mean that one of the banks is wiped out without any increase of banking facilities to the public?

My reason for asking these questions—which I do with diffidence, and in no spirit of adverse criticism—is because I find it difficult to get them answered in London, and until they are answered it is impossible for Englishmen to appreciate the admitted defects in the banking system of the United States.

REGINALD MURRAY.

Dr. James Douglas, to whom the foregoing letter has been submitted, writes as follows:—

I regret that I am not sufficiently conversant with the banking laws of the United States to answer Mr. Murray's questions. I am, however, sure that the Sherman Act has had little influence on the action of the banks in their transaction of strictly banking business. The incorporation of banks has been under State laws, and no State can authorise a bank to erect branches in another State: hence the concentration of capital at the great financial centres instead of its diffusion. As in Canada, under its banking laws a State bank may become a National bank, and thus secure the right of issuing notes, which are guaranteed by the Federal Government by submitting to rigid Federal inspection and other conditions, but it does not thereby secure the right to organise branches outside the State. The effect has been virtually to stop the issuing of banknotes by State institutions. These notes used to be current generally only in the State where issued, and were often refused, except in the neighbourhood where the managers of the banks were well known.

I believe, however, that there is a very widespread desire that Congress should pass a Federal Banking Act, which would remedy the defects of the present banking system and remove its limitations.

NOTES ON BOOKS.

FARM WEEDS OF CANADA. By George H. Clark, B.S.A., and Andrew Fletcher, LL.D., F.L.S., with Illustrations by Norman Criddle. Second edition. Revised and enlarged by George H.

Hosted by Google

Clark. Dominion of Canada, Department of Agriculture, Branch of the Seed Commissioner. Published by direction of the Hon. Sydney A. Fisher, Minister of Agriculture, Ottawa, 1909. For sale in single copies only. Government Printing Office Bureau, Ottawa. Price, $1 [5*s*.].

It is impossible to take up for review this model "Blue Book," as we should call it here, without being predisposed in its favour by the patriotic enthusiasm enkindled in this country on the vital question of the future of the British races in America by the speeches of Earl Grey on his recent return, as the retired Viceroy, from Canada, and the speech, the most inspiring on its direct subject known to me, by Sir Henry Mortimer Durand, our late Ambassador at Washington, from the Chair of the Royal Society of Arts, on the 22nd ult., at the lecture by the learned Dr. James Douglas on "The Industrial Progress of the United States." But the volume needs no such adventitious and fortuitous aids to force a reader's favour and reinforce his confidence. It commends itself all-sufficingly at a glance, and in its entirety, and in every detail. It is not issued in a flimsy paper wrapper, and weakly stitched together, as is an English "Blue Book," but in a crimson leather binding, lined with watered crimson silk, and with the sheets and binding so strongly "forwarded" that it is ready forthwith for its abiding place on the library shelf. It is beautifully printed throughout in large type; and the coloured illustrations are at once most truthful portraits and charming pictures. They are drawn with such precision, and force, and in such correct perspective, that looked at with half-closed eye-lids, they stand out in the fullest stereoscopic relief, and the actuality of the living plants themselves, "all a-growing, all a-blowing": and they are all such healthy, fresh, and creditable specimens of their species! As for the text, in its scientific botany, its agricultural botany, and its popular and literary botany, it is in every way admirable, and an exemplar for even the Governments of America, and India, and Germany, in all such official publications. In a word, the volume in its contents plays up to the titlepage, and the titlepage is found an absolute warranty of the worth of its contents; and that is why I have copied it out and paraded it at full length at the head of this Note.

The book is full of multifarious features of interest; but I will only refer to the few that most interest myself. Of the 76 full-page coloured illustrations, 71 are of plants, and five of 100 magnified samples of seeds; while of the 71 illustrations of plants, eight are of endogenous species, grasses, sedges, and the like, and 63 of exogenous species, or bright flowering herbaceous field plants; and of these, 40 are common to England and Canada, and only 23 indigenous to Canada—or, at least, plants naturalised in Canada from other countries than Great Britain and Ireland. These 23 are:—*Amaranthus retroflexus*, Chinaman's grass; *Ambrosia trifida*, Crown weed, King weed; *A. Artemisifolia*, Roman Wormwood; *Aryxis Amarantoides*, Russian Pigweed; *Brassica orientalis*, Rabbit-Ear, Klinkweed; *Circium arbense*, Soft Field Thistle; *Draba nemorosa*, Yellow Whitlow grass; *Hieracium praealtum*, King Devil, Gochnat; *Iva axillaris*, "Poverty Weed"; *Lactuca pulchella*, Blue Lettuce; *Lappula echinata*, Blue-bur, Sheep-bur; *Lepidium apetalum*, Pepper-grass; *Œnothera pallida*, "Evening Primrose; *Neslia paniculata*, Ball Mustard; *Potentilla monspelensis*, Rough Cinquefoil; *Rumex crispus*, Yellow Dock; *Rudbeckia hirta*, "Black-Eyed Susan"; *Silene noctiflora*, Night-flowering Catchfly; *Sisymbrium altissimum*, Tumble Mustard; *S. incisum*, Tansy Mustard; *Solidago graminifolia*, "Golden Rod"; *Spiraea tomentosa*, Steeple-Bush, and *Vicia angustifolia*, Wild-Tare, Wild-Vetch, and Wild-Pea.

Among the remaining 40 illustrated plants, common to England and Canada, there is no note of either the "Red Poppy," the "Blue Bottle" [*Centaurea Cyanus*], or the "Common Camomile," the commonest of the loveliest weeds in English cornfields. *Erigeron Canadensis*, is, on the other hand, the only Canadian field plant that has become apparently naturalised in Great Britain.

Another remarkable thing about these Anglo-Canadian plants is the haphazard way in which their English names have been attached to them. Thus, in the foregoing list, "Golden Rod" is the name attached in England to *Solidago Vergaurea*, also called "Aaron's Rod" by us, and to *Verbascum Thapsus;* "Black-eyed Susan" to an Anglo-Indian garden plant, the once familiar scientific name of which I am no longer able to recall; "Evening Primrose" to *Œnothera biennis;* and "Poverty-weed" to *Melampyrum arvense*, and *Chrysanthemum leucanthemum.* All this is very puzzling, and reaches its climax in the case of *Erigeron Canadensis*, called by the Canadians by the names of "Fleabane," the name in England of *E. acre;* and "Butter-weed," the name in England of *Pinguicula vulgaris;* and "Fireweed," our *Plantago media;* and "Mare's-tail," our *Hippuris vulgaris;* and "Blood Staunch," a corruption of "Blood Strange," i.e., "constringe," our name of *Mimulus minimus;* and "Bitter Weed," our name for various species of *Populus.*

Another point of interest in this connection is the disappearance from Canada of almost all the English sacred names of plants, whether these plants have been imported from England, or are indigenous to Canada; of such names, for instance, as "God's Eye," "Aaron's Beard," "Angel Eyes," "Jacob's Ladder," "Noah's Ark," "Herb Grace," "Star of Bethlehem," "Virgin's Bower," "Our Lady's Pincushion," etc., "Mary's Thistle," etc., "Herb Christopher," etc., to about a hundred of like names; of all of which they only retain in Canada, as it would seem, Holy Grass, applied, as a direct translation to *Hierochloe odorata;* "Herb-John," as in England, to "St. John's Wort" [*Hypericum perfoliatum*]; "St. James' Wort" also applied, as in England, to *Senecio Jacobæa.*

Hosted by Google

The name of "Bur Marigold" is also applied to various species of *Bidens*, as in England, to *B. tripartita*, and they give the name of Lady's Thumb to *Polygonum Persicaria*, our "Virgin Mary's Pinch"; which, however, may not have a sacred Christian, but rather a profane origin, this plant being also our "Saucy Alice." All heroical names also have disappeared from the popular nomenclature of Canadian "Farm Weeds." But it is very interesting to find in the Canadian name of Crown weed, given to *Ambrosia trifida*, associated as it is with Kingweed [which latter in the form of "King's Crown," is the English name of *Viburnum Opulus*, and *Melilotus officinalis*] a reminiscence of the true old English names, "Coronation," and "Crownation" [and not the nonsensical "Carnation"], of *Dianthus Caryophyllus*.

Most of our old English picturesque and romantic names of plants have been perpetuated in Canada, and some new ones added, as:—Rainbow, of *Amaranthus tricolor*, our August Flower, and "Florimor"; Fall Dandelion, *Leortodon autumnalis*, our name for which is unnameable; Blue Sailors, *Chicorium Intybus*, our "Chicory"; Blue Devil, *Echium vulgare*, our "Bugloss" and "Saviour's Flannel"; Bouncing Bet, *Saponaria officinalis*, our "Soapwort"; Chinaman's Greens, *Amaranthus retroflexus;* French Weed, *Thlaspi arvense;* King Devil, *Hieracium præaltum;* Devil's Paint Brush, *Hieracium aurantiacum*, our "Grim the Collier"; and Russian Tumble-weed, *Salsola Kali*, our "Glass-wort."

Unnameable names have also been altogether expurgated from the vernacular Canadian nomenclatures; and this is very notable, considering how numerously and widely they still live among the rural communities of England. But they are not a certain criterion of any exceptional coarseness of imagination on the part of the people of this country; while the universal prevalence of such objectionable names in the vernacular languages of India, without the slightest idea among the Hindus, or any but Moslems and our English folk, of there being anything improper in them, would seem to indicate that their existence in England is but a survival of the pagan period of Europe when every natural object of the remotest phallic suggestiveness, in colour, form, etc., was accepted as an apocalyptic symbol of the Almighty Creator of all the material existences through which He is first apprehended by mankind. Like the polygamy, the *harim*, and the "seraglio," of Islam, these, to us, prurient names, have, at least in India, an obvious hieropsychic origin, and are there everywhere still of sacro-sanct significance. The people of the historical East have always looked the Cosmos full in the face, and ingenuously yielded themselves to its every genial impulse as of divine ordination; and as for the opinion of others —*Honi soit qui mal y pense.*

But the most moving interest of "Farm Weeds" is the hope it justifies in the future of the British races in North America; for where British plants, or plants closely allied to them, flourish, and even in greater vitality than in the United Kingdom, there English, and Welsh, and Scots, and the Irish are sure to flourish also. There is no future for any European race in South Africa, for, from south to north, Africa is all a "Black Man's," that is, a true Negro's country. Not even the Semitic race survives there long in the superb condition in which it is found in Arabia, and Anterior Asia; and the tragedy of the Saracens was that they admitted the Negro, and the degenerated, that is negroised Hamites of ancient Egypt into Islam on equal terms with themselves. The Spaniards in their turn committed the similar error in receiving the aborigines of South America into the Holy Catholic Church in an unqualified spirit of Christian brotherhood. The danger before the United States is in the fact that they nearly all lie within the tropical and sub-tropical latitudes of "the Spanish main"; within which all mammals are found of dwindled types, camels as "lamas," lions and tigers as "jaguars," and "pumas," and "ocelots," etc., and aboriginal man as Aztecs. Only in Canada and "the Rockies" do we find the "bison" and the great bears; and all through the latitudes of "the Spanish Main" the European races are found, just as in India, rapidly to Creolise, that is with the very first generation of "the native born"; and in Spanish America, at least, this degeneration of the European Spaniards has been greatly aggravated by their intermarriages with the Christianised descendants of the autochthons of the country. The people of the United States of America, from New York southward, are exposed to the same menace unless they defend themselves against it by the severest immigration, and Negro and Red Man "Reservations" regulations. The intuitive dread of this menace is the true explanation of all the "Negro-baiting" that goes on in the Southern States of the North American Republic; and of the Negro-baiting that prevailed at one time in South Africa, until repressed by the Imperial Government. But in Canada the salubrious severity of the climate, and the strong conservatism of the original religious French and religious Scottish settlers there, are factors full of hope for the future of these two noble races, and of any other races of Northern Europe emigrating to the Dominion; a hope emphatically supported by this official report on its "Farm Weeds." People sometimes talk of the annexation of the Dominion by the United States, but those who will compare these illustrations of European plants naturalised in Canada, with others of the same plants cultivated in the midland and southern States of the United States, will not fail to recognise that in "the course of nature" Canada is much more likely in the far future to annex the United States. And as for this "old country" of our own, Shelley's hypothetical "Transatlantic Commentator" will, of a certainty, never find the ruins of St. Paul's and the Abbey Church of Westminster "a habitation of bitterns." By the betokenings of every wild flower of our own green fields and "tumbled" hedges, we shall go our accustomed way surmounting

Hosted by Google

every difficulty to the last, and stand in our hard won lot to the end of time, — time as measured out by the passing physiographical dispensation of this terraqueous globe.

George Birdwood.

Official Report of the Japan-British Exhibition, 1910. London: Unwin Brothers, Ltd.

The Japan-British Exhibition at Shepherd's Bush was acknowledged on every hand to be an unqualified success, and one can hardly give higher praise to the official report than by stating the bare truth that it is a worthy record of a remarkable achievement. In the paper which he read before the Society in January, 1910, Count Hirokichi Mutsu, the Imperial Japanese Government Commissioner, described in considerable detail the steps which were being taken in his native country to get together and transport to London an exhibition representative of Japanese arts and industries. Those who visited Shepherd's Bush know to what an extent success rewarded these efforts, but few probably realised the enormous labour that was entailed. "Great difficulty," says the report, "was involved in bringing from Japan many of the plants and trees required. Some of them were shipped through the Indian Ocean, while others, in order to prevent their premature blooming when passing the tropic climes, were sent by way of America. The extreme hardship to plant life involved in this procedure can be realised when we consider the parallel case that, out of many thousands of goldfish which were brought over from Japan with the greatest care, and were tended by a special skilled attendant on the way, only less than a hundredth part of the number were alive when they arrived at Shepherd's Bush."

Although, perhaps, in other departments the difficulties of transport were not so formidable, still, in view of the enormous distance that separates Japan from London, it speaks well for the organisers of the exhibition that everything was practically complete by the time fixed for the opening. That the exhibition was appreciated is effectively proved by the fact that the number of visitors was over 8,350,000. As to its effects in stimulating trade, Mr. Hikojiro Wada, Commissioner-General of the Imperial Japanese Government to the exhibition, stated that in consequence of it many new markets were opened up for Japanese goods, and over £60,000 worth of Japanese exhibits were sold at Shepherd's Bush. A considerable number of letters from some of the best known furnishing and other firms in London are printed in the report, all bearing striking testimony to the large increases in the sale of Japanese goods in this country.

The report is profusely illustrated with photographs, many of which represent well-known objects both of British and Japanese art.

The Works of Man. By Lisle March Phillipps. London: Duckworth & Co. 7*s*. 6*d*. net.

As the somewhat comprehensive title of this book gives little clue to its contents, it may be as well to state at once that it deals with the consideration of art, or rather architecture, not from the æsthetic standpoint, but "as an expression of human life and character." Mr. Phillipps selects several of the principal styles of architecture—Egyptian, Greek, Arab, Gothic, Renaissance, etc.—and endeavours to show how each reflects the mental state of the nation which produced it. Thus, "the sausage-shaped columns of Egyptian temples and the squat and shapeless entablatures, so blind to all structural purpose, so intellectually unconscious of their relation and proportion to each other, have seemed the mere expression of the state of intellectual insensibility in which they were conceived." In Greek art, again, the awakening which we see, and the revolt from the stereotyped forms of the earlier Egyptians, is the reflection of a mental awakening: the Greek, with his keenly intellectual alertness, was driven, as Professor Ernest Gardner says, "to direct study and observation of nature," whereby sculpture in his hands became individual, flexible, and expressive. Arab architecture, too, with "the whimsically shaped arches, the ingeniously tangled designs, and all the medley of fantastic notions and experiments, tossed together in the flimsiest manner of construction possible," is a direct reflection of the Arab character, "so impulsive, yet so fickle and unstable in all its impulses."

These, and such as these, are the ideas which Mr. Phillipps has elaborated in his volume (of which, by the way, most of the material has already appeared in articles in the *Edinburgh* and *Contemporary Reviews*). Those to whom these ideas are fresh will find much to interest them in the book; while those who wish to carry their study of the subject a little further will be grateful for the bibliography. Mr. Phillipps's selection of authorities appears to be excellent—especially his repeated advice to those eager to understand the Greek spirit, "Concentrate on Professor Butcher." Probably no man in modern times has been more thoroughly imbued with it than the great scholar, and Mr. Phillipps is wise when he writes: "Professor Butcher's works seem to me to give a clearer idea of the Greek ideal in matters of thought and character than any I have met with."

GENERAL NOTES.

Optical Convention, 1912.—It has been decided to hold an Optical Convention and Exhibition of Optical and Allied Instruments in 1912. The objects of the Convention have been defined as follows:—

1. To ascertain and demonstrate the various modes in which (*a*) theoretical science can be

Hosted by Google

utilised to further industrial development; (*b*) the study of practical problems can be employed to give direction to theoretical teaching and investigation; (*c*) the practice of experiment can be usefully employed in the teaching of optical science.

2. To bring to the knowledge of the purchaser of optical and other scientific instruments, by means of the exhibition in London, and by means of the catalogue in the provinces, in the colonies, and in foreign countries, what are the resources of British manufacturers.

3. To collect, to ventilate, and to subject to efficient criticism, such proposals as have for their object the better organisation of the British optical industry, and the improvement, in any way, of British optical manufactures.

4. To ascertain and make known existing wants and deficiencies.

The exhibition will be essentially a British exhibition, and will comprise, in addition to a trade exhibition confined to British manufacturers, a loan collection of instruments and apparatus of historical and scientific interest, which may be of British or foreign manufacture, and which shall be selected with a view to subserving the educational and scientific objects of the Convention. Guarantors of £5 and upwards, and donors of £1 and upwards, will be enrolled as Founder Members of the Convention, and entitled as such, in addition to the other privileges of membership, to receive presentation copies of the proceedings and catalogue. The subscription for ordinary membership will be five shillings.

Further particulars may be obtained of the Honorary Secretary, Mr. J. W. Gordon, 113, Broadhurst Gardens, Hampstead, N.W.

Royal Meteorological Society.—The Council of the Royal Meteorological Society have awarded the Symons Gold Medal to Professor Cleveland Abbe, of the United States Weather Bureau, in recognition of the valuable work which he has done in connection with meteorological science. The medal will be presented at the annual meeting of the Society on January 17th, 1912.

Distribution of the Population in Spain.—Recent census returns show that the density of the population of Spain is only 101 per square mile. Extensive regions in the country are practically unpeopled. For example, in the province of Soria, with an area of 3,836 square miles, and the province of Cuenca, with 6,725 square miles, the number of inhabitants ranges as low as thirty-nine to the square mile. Out of a total of forty-nine provinces, twenty-two figure below the general average for the whole of Spain. They are, with the exception of the province of Huelva, all in the interior of the Peninsula, and once formed the ancient kingdoms of Leon, Aragon, Castile and Upper Andalusia. This group represents a population engaged mainly in agricultural pursuits, although mining and manufacturing are carried on on a small scale. Of the provinces containing more than the general average of population per square mile, Barcelona and Biscaya are the most densely populated, the figures being 383 and 435 respectively. In the more thickly settled provinces the people are devoted to agriculture, and are also largely engaged in manufactures and commerce. With few exceptions the chief centres of population in Spain are situated south of Madrid.

Number of Visitors to the Turin Exhibition.—Since the opening, on April 29th last, to September 19th inclusive, the total number of visitors to the exhibition at Turin was 4,012,776. The influx of visitors during the last few weeks increased considerably. The average number during the first ten days of September reached 48,000 of persons on week-days and over 100,000 on Sundays.

Big Trees in Belgium.—A monograph on trees, lately published in Brussels, gives some interesting facts respecting the size of some of the big trees growing in the forests of Belgium. Of these, the famous "Oak of Liernu," in the Province of Namur, said to be the largest in the kingdom, measures 9 metres (29 ft. 6 in.) in girth at a height of 1·50 metres (5 ft.) above ground. The "Bornival" oak, in the neighbourhood of Nivelles, is 6·20 metres (20 ft. 4 in.) in girth; another near Lummen, 5·20 metres (17 ft.), and the Oak of Charles V. near Brussels, which measures 5·15 metres (16 ft. 8 in.). Amongst lime trees, one at Vosselacre, near Ghent, measuring 6·70 metres (22 ft.) in girth, and another at Bermont, near Huy, of 7 metres (23 ft.), are probably the largest. Of other trees, the so-called "arbre ballon" near Brussels, with a girth of 4½ metres (14 ft. 9 in.), stands 20 metres (65 feet) high.

Cotton Growing in Algeria.—The cotton-growing prospects in Algeria appear to be very encouraging, especially in the Chétiff district, where most satisfactory results have been obtained, thanks to the initiative of some of the leading agriculturists. According to a Marseilles journal, the net profits of this cultivation in Algeria have been as much as from 340 francs to 770 francs per hectare (£5 10*s*. 2*d*. to £12 9*s*. 5*d*. per acre) in bad seasons, whilst as much as 870 francs to 1,200 francs per hectare (£14 2*s*. 2*d*. to £19 8*s*. 9*d*. per acre) has been realised net for the crop. The average net profit in America ranges from 120 francs to 150 francs per hectare (£1 18*s*. 10*d*. to £2 8*s*. 7*d*. per acre), and in Egypt between 95 francs and 110 francs (£1 10*s*. 8*d*. to £1 15*s*. 7*d*. per acre) only. At the present time the area planted with cotton in Algeria is about 1,200 hectares (about 3,164 acres). In the neighbourhood of Orleansville the cultivation of cotton is confined entirely to the irrigated lands. As a result of the introduction of cotton-growing in Algeria, an oil mill for treating the seed has lately been opened at Orleansville.

THE LIBRARY.

The following books have been presented to the Library since the last announcement:—

Arias, Harmodio, B.A., LL.B.—The Panama Canal. London: P. S. King and Son, 1911. Presented by the Publishers.

Berry, A. J., M.A.—Scotland, Ireland, and Britain Overseas. London: Blackie and Son, Ltd., 1911. Presented by the Publishers.

Briggs, R. A., F.R.I.B.A.—The Essentials of a Country House. London: B. T. Batsford, 1911. Presented by the Publisher.

Bright, Charles, F.R.S.E., M.Inst.C.E., M.I.E.E.—Imperial Telegraphic Communication. London: P. S. King and Son, 1911. Presented by the Author.

Britten, F. J.—Old Clocks and Watches and their Makers. Third Edition. London: B. T. Batsford, 1911. Presented by the Publisher.

Brown, G. Baldwin, M.A.—The Arts and Crafts of our Teutonic Forefathers. London: T. N. Foulis, 1910. Presented by the Publisher.

Clemson, H.—1. Methods and Machinery of Business. Second Edition. 2. Office Procedure and Business Correspondence. London: Butterworth and Co., 1911. Presented by the Publishers.

Cole, F. J., D.Sc.—An Analysis of the Church of St. Mary, Cholsey, in the County of Berkshire. Oxford: B. H. Blackwell, 1911. Presented by the Publisher.

Coutts, H. T., and G. A. Stephen.—Manual of Library Bookbinding. London: Libraco, Ltd., 1911. Presented by the Publishers.

Darling, Henry A.—A Course of Elementary Workshop Arithmetic. London: Blackie and Son, Ltd., 1911. Presented by the Publishers.

de Selincourt, Basil.—William Blake. London: Duckworth and Co., 1911. Presented by the Publishers.

Douglas, Loudon M., F.R.S.E.—The Bacillus of Long Life; a Manual of the Preparation and Souring of Milk for Dietary Purposes. London: T. C. and E. C. Jack, 1911. Presented by the Publishers.

Dudley, Lucy Bronson.—A Writer's Inkhorn. New York, 1910. Presented by the Author.

Dugmore, A. Radcliffe.—Les Fauves d'Afrique photographiés chez eux. Paris: Librairie Hachette et Cie, 1910. Presented by the Publishers.

Edge, J. Harold, F.C.S.—Notes on Practical Cotton Finishing. London: The Trades Papers Publishing Co., Ltd., 1911. Presented by the Publishers.

Fowle, F. E.—Smithsonian Physical Tables. Fifth Edition. Washington, 1910. Presented by the Smithsonian Institution.

Gardner, Ernest A., M.A.—Six Greek Sculptors. London: Duckworth and Co., 1911. Presented by the Publishers.

Gillies, H. Cameron, M.D.—Regimen Sanitatis. Glasgow: Robert Maclehose and Co., Ltd., 1911. Presented by Sir George Birdwood, K.C.I.E., C.S.I., M.D., LL.D.

Godfrey, Walter H.—1. A History of Architecture in London. 2. The English Staircase. London: B. T. Batsford, 1911. Presented by the Publisher.

Gould, F. J.—Youth's Noble Path. London: Longmans, Green and Co., 1911. Presented by the Publishers.

Hart, John Hinchley, F.L.S.—Cacao, its Cultivation and Curing. London: Duckworth and Co., 1911. Presented by the Publishers.

Hooper, Luther.—Silk, its Production and Manufacture. London: Sir Isaac Pitman and Sons, Ltd., 1911. Presented by the Publishers.

Inwards, Richard.—William Ford Stanley, his Life and Work. London: Crosby Lockwood and Co., 1911. Presented by the Publishers.

Jackson, William.—Dictionary of English and Spanish Technical and Commercial Terms. London: E. and F. N. Spon, Ltd., 1911. Presented by the Publishers.

Jacobs, Herbert, B.A.—Stevens' Elements of Mercantile Law. Fifth Edition. London: Butterworth and Co., 1911. Presented by the Publishers.

Jameson, P. R.—Weather aud Weather Instruments. Rochester, U.S.A.: Taylor Instrument Companies, 1908. Presented by the Author.

Japan-British Exhibition, 1910.—Official Report. London: Unwin Brothers, Ltd., 1911. Presented by Imre Kiralfy, Esq.

Jerusalem Sous Terre.—Les récentes fouilles d'Ophel, décrites par H. V. London: Horace Cox, 1911. Presented by the Publisher.

John Rylands Facsimiles.—1. Propositio Johannis Russell. 2. "Dives Pragmaticus," London, 1563. 3. "A litil boke for the Pestilence." Manchester: University Press, 1909 and 1910. Presented by Sir George Birdwood, K.C.I.E., C.S.I., M.D., LL.D.

Johnson, V. E., M.A.—The Gyroscope. London: E. and F. N. Spon, Ltd., 1911. Presented by the Publishers.

Lamb, Sir John Cameron, C.B., C.M.G.—The Life-Boat and its Work. London: Wm. Clowes and Sons, Ltd., 1911. Presented by the Author.

Laurie, A. P., M.A., D.Sc.—The Materials of the Painter's Craft from the earliest times to the end of the 17th Century. London: T. N. Foulis, 1910. Presented by the Publisher.

Layng, A. E., M.A.—A General Text-Book of Elementary Algebra. Book II. Blackie and Son, Ltd., 1910. Presented by the Publishers.

Hosted by Google

Leeming, F. B. — Guide to the Income-Tax. London: Effingham Wilson, 1911. Presented by the Publisher.

Lethaby, W. R.—Mediæval Art. London: Duckworth and Co., 1911. Presented by the Publishers.

Lilienthal, Otto. — Birdflight as the Basis of Aviation. Translated from the German by A. W. Isenthal. London: Longmans, Green and Co., 1911. Presented by the Publishers.

Magnus, Sir Philip, M.P. — Educational Aims and Efforts, 1880–1910. London: Longmans, Green and Co., 1910. Presented by the Author.

Mauclair, Camille.—Antoine Watteau (1684–1721). London: Duckworth and Co., 1911. Presented by the Publishers.

Michell, J. E., M.A., Ph.D. — English-French Unseens. London: Blackie and Son, Ltd., 1911. Presented by the Publishers.

Moore, James M., M.A., and John Slight, M.A. —An Intermediate French Course. Part III. London: Blackie and Son, Ltd., 1911. Presented by the Publishers.

Murdoch, W. H. F., B.Sc.—The Ventilation of Electrical Machinery. London: Whittaker and Co., 1911. Presented by the Publishers.

Phillipps, Lisle March. — The Works of Man. London: Duckworth and Co., 1911. Presented by the Publishers.

Pickworth, Charles N. — 1. Logarithms for Beginners. Third Edition. 2. The Slide Rule. London. Whittaker and Co., 1911. Presented by the Publishers.

Piggott, Sir Francis.—Studies in the Decorative Art of Japan. London: B. T. Batsford, 1910. Presented by the Publisher.

Porter, Robert P.—The Ten Republics. London: George Routledge and Sons, Ltd., 1911. Presented by the Author.

Ranking, D. F. de l'Hoste, M.A., LL.D., and Ernest Evan Spicer, F.C.A., and Ernest C. Pegler, F.C.A.—Mercantile Law. London: H. Foulks Lynch and Co., 1911. Presented by the Publishers.

Richardson, A. E., and C. Lovett Gill.—London Houses from 1660 to 1820. London: B. T. Batsford, 1911. Presented by the Publisher.

Royal Society.—Catalogue of a Collection of Early Printed Books in the Library. London, 1910. Presented by the Royal Society.

Schlich, Sir William, K.C.I.E., Ph.D., F.R.S.—Manual of Forestry. Vol. III. Forest Management. Fourth Edition. London: Bradbury, Agnew and Co., Ltd., 1911. Presented by the India Office.

Spiller, G.—Papers on Inter-Racial Problems communicated to the First Universal Races Congress, London, 1911. London: P. S. King and Son, 1911. Presented by the Publishers.

Stevens, Alfred.—The Wide Range Dividend and Interest Calculator. London: E. and F. N. Spon, Ltd. Presented by the Publishers.

Strachan, Richard, F.R.Met.Soc.—Basis of Evaporation, etc. London: Williams and Strahan, 1910. Presented by the Author.

Tomes, B. A.—A First Course in Practical Mathematics. London: Blackie and Son, Ltd., 1910. Presented by the Publishers.

Tookey, W. A.—How to Manage a Suction Gas Producer. London: Percival Marshall and Co., 1911. Presented by the Publishers.

Tremearne, Mary and Newman.—Fables and Fairy Tales for Little Folk. Cambridge: W. Heffer and Sons, Ltd., 1910. Presented by the Publishers.

Webb, Herbert Laws, M.I.E.E.—The Development of the Telephone in Europe. London: Electrical Press, Ltd., 1911. Presented by the Author.

Webster's New International Dictionary of the English Language. London: G. Bell and Sons, Ltd., 1911. Presented by C. O. Sylvester Mawson, Esq.

Weston, Agnes, LL.D.—My Life among the Bluejackets. London: James Nisbet and Co., Ltd., 1911. Presented by the Author.

Whittaker's Arithmetic of Electrical Engineering. Second Edition. London: Whittaker and Co., 1911. Presented by the Publishers.

Willmott, Ernest, F.R.I.B.A. — English House Design. London: B. T. Batsford, 1911. Presented by the Publisher.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings, at 8 o'clock:—

December 6.—J. A. J. de Villiers, "British Guiana and its Founder—Storm Van 's Gravesande." Lord Reay, G.C.S.I., G.C.I.E., LL.D., will preside.

December 13.—W. Yorath Lewis, M.Am. Soc.M.E., A.M.I.Mech.E., A.M.I.E.E., "Continuous Service in Passenger Transportation."

Indian Section.

Thursday afternoon, at 4.30 o'clock:—

December 14.—J. Travis Jenkins, Ph.D., D.Sc., Superintendent of the Lancashire and Western Sea Fisheries, "Fisheries of Bengal." Sir Steuart Colvin Bayley, G.C.S.I., C.I.E., will preside.

Cantor Lectures.

Monday evenings, at 8 o'clock:—

Professor Vivian B. Lewes, "The Carbonisation of Coal." Four Lectures.

Syllabus.

Lecture II. — December 4. — *The Methods Employed in the Destructive Distillation of Coal.*—

Hosted by Google

The changes which have taken place during the last century in the forms and settings of gas retorts—The developments of the last ten years and present position of the gas industry—The coke industry and the gradual development of the modern recovery plant—The influence of the retort or oven on the carbonisation.

LECTURE III. — DECEMBER 11. — *The Thermal Conditions existing during the Carbonisation of Coal.*—The heat of formation of coal—The work of Euchene, Mahler, and others—The cause of the endothermic nature of some coals—The thermal value of the reactions taking place in the retort—The losses of heat in a retort setting—The transmission of heat through the retort and charge—The effect of temperature and travel on the primary products of decomposition — The temperatures existing in retorts and ovens—Small charges and full charges—The influences which lead to improvement in the products from full charges, chamber and vertical retorts.

LECTURE IV. — DECEMBER 18. — *The Possible Improvements in Carbonisation.*—The aims of the gas manager and coke producer—Experiments on low temperature distillation and their teaching—The rivalry existing between fully-charged retorts, vertical retorts, recovery ovens, and chamber carbonisation — The intermittent vertical retort *versus* the continuous vertical systems—The Settle-Padfield, Duckham-Woodall, and Glover-West processes—The ideals of carbonisation—The volume of gas due to primary and secondary reactions—The gasification of tar—The limitations of volume and quality of gas—The ends to keep in view in devising new processes of carbonisation.

Papers to be read after Christmas:—

CECIL THOMAS, "Gem Engraving."

F. MARTIN DUNCAN, "The Work of the Marine Biological Association."

H. A. ROBERTS, M.A., "The Relations of Science to Commerce and Industry."

JOHN NISBET, D.Oec., late Conservator of Forests, Burma, "The World's Decreasing Timber Supplies."

FRANK WARNER, "Silk."

CHARLES C. ALLOM, "The Development of Artistic Skill in the Applied Arts."

CYRIL DAVENPORT, "Illuminated MSS."

ERNEST KILBURN SCOTT, Assoc.M.Inst.C.E., M.I.E.E., "The Manufacture of Nitrates from the Atmosphere."

CHARLES BRIGHT, F.R.S.E., M.Inst.C.E., M.I.E.E., "The Administration of Imperial Telegraphs."

HAROLD COX, "The Interdependence of Morals and Economics."

PROFESSOR G. W. OSBORN HOWE, "Recent Progress in Radio-Telegraphy."

E. D. MOREL, "British Rule in Nigeria."

GORDON CRAIG, "Stage Illusion."

THEODORE E. SALVESEN, "The Whaling Industry of To-day."

LEONARD HILL, M.B., F.R.S., and MARTIN FLACK, M.A., M.B., B.Ch., "The Influence of Ozone in Ventilation."

PROFESSOR ERNEST A. GARDNER, M.A., "Greek Sculpture."

GEORGE FLETCHER, "Technical Education in Ireland."

E. A. GAIT, I.C.S., C.I.E., Census Commissioner for India, "The Indian Census of 1911."

WALTER SAISE, D.Sc., M.Inst.C.E., F.G.S., "The Coal Industry and Collier Population of Bengal."

NEVILLE PRIESTLEY, Managing Director, South Indian Railway, "Indian Railways."

W. A. LEGG, M.Inst.C.E., "Irrigation in South Africa."

ALAN BURGOYNE, M.P., "Colonial Vine Culture."

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

January 18, February 8, March 14, April 25, May 16.

COLONIAL SECTION.

Tuesday afternoons, at 4.30 o'clock:—

January 30, February 27, March 26, May 7.

CANTOR LECTURES.

Monday evenings, at 8 o'clock:—

VAUGHAN CORNISH, D.Sc., F.G.S., F.C.S., "Ocean-Waves, Sea-Beaches, and Sandbanks." Two Lectures.

January 22, 29.

LOUDON M. DOUGLAS, "The Meat Industry." Three Lectures.

February 5, 12, 19.

LUTHER HOOPER, "Hand-Loom Weaving." Three Lectures.

February 26, March 4, 11.

NOEL HEATON, F.C.S., "Materials and Methods of Decorative Painting." Three Lectures.

March 18, 25, April 1.

HOWARD LECTURES.

Monday evenings, at 8 o'clock:—

CAPTAIN H. R. SANKEY, R.E., M.Inst.C.E., "Heavy Oil Engines." Four Lectures.

April 29, May 6, 13, 20.

JUVENILE LECTURES.

Wednesday afternoons, at 5 o'clock:—

CHARLES VERNON BOYS, F.R.S., "Soap Bubbles." Two Lectures.

January 3, 10.

Hosted by Google

MEETINGS FOR THE ENSUING WEEK.

MONDAY, DECEMBER 4...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Professor Vivian B. Lewes, "The Carbonisation of Coal. Lecture II. — The Methods Employed in the Destructive Distillation of Coal."

Farmers' Club, Whitehall Rooms, Whitehall-place, S.W., 6 p.m. 1. Annual General Meeting. 2. Professor Penberthy, "The Present Position of the Tuberculosis Question."

Engineers, at the Institution of Electrical Engineers, Victoria-embankment, W.C., 7.30 p.m. Mr. Henry Adams, "The Design of Tall Chimneys."

Chemical Industry (London Section), Burlington House, W., 8 p.m. 1. Mr. W. C. Hancock, "Physical Properties of Clays." 2. Dr. J. Gordon Parker and Mr. J. R. Blockey, "The Value of the Non-tannins in the Formation of Leather." 3. Mr. L. A. Levy, "The Estimation of Carbon Monoxide." 4. Mr. R. G. Pelly, "The Composition of Bassia Fats."

Geographical, Burlington-gardens, W., 8.30 p.m. Sir Alfred Sharpe, "The Geography and Economic Development of British Central Africa."

Victoria Institute, 1, Adelphi-terrace House, W.C., 4.30 p.m. Mrs. Agnes Smith Lewis, "The Genealogies of our Lord in St. Matthew and St. Luke."

London Institution, Finsbury-circus, E.C., 5 p.m. Professor Selwyn Image, "The Meaning and Importance of Decorative Art."

TUESDAY, DECEMBER 5...Roman Studies, Society for the Promotion of, at the Society of Antiquaries, Burlington House, W., 4.30 p.m. Mr. R. H. Forster, "The Corbridge Excavations, 1911."

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Discussion on Mr. R. T. Smith's paper, "Electric Lighting of Railway Trains: the Brake-Vehicle Method."

Photographic, 35, Russell-square, W.C., 8 p.m. Dr. C. R. Atkin Swan, "The Simplicity of Telephotography."

Colonial, Whitehall Rooms, Whitehall-place, S.W., 8.30 p.m. Lord Plunket, "The Outlying Islands of New Zealand."

Horticultural, Vincent-square, Westminster, S.W., 3 p.m. Professor J. B. Farmer, "Climbing Plants as a Biological Study."

WEDNESDAY, DECEMBER 6...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. J. A. J. de Villiers, "British Guiana and its Founder—Storm van 's Gravesande."

Accountants, Incorporated Students' Society of, 50, Gresham-street, E.C., 6.30 p.m. Mr. A. C. Gillman, "Gas Accounts."

Geological, Burlington House, W., 8 p.m.

Automobile Engineers (Graduates' Section), 13, Queen Anne's-gate, S.W., 8 p.m. Mr. G. M. Junner, "Carburation."

Public Analysts, at the Chemical Society's Rooms, Burlington House, Piccadilly, W., 8 p.m. 1. Mr. J. A. Brown, "The Estimation of Small Quantities of Essential Oil in Spices, etc." Part II. 2. Messrs. L. Eynon and J. H. Lane, "The Determination of Furfural by means of Fehling's Solution." 3. Messrs. J. H. Coste, E. T. Shelbourn, and E. R. Andrews, "The Examination of Petroleum Mixtures." 4. Messrs. G. C. Jones and R. F. Easton, "Note on Ground Almonds." 5. Messrs. C. Beadle and H. P. Stevens, "A Method for Determining the Amount of Insoluble Particles in Raw Rubber." 6. Mr. C. Simmonds, "Note on the Determination of Small Quantities of Methyl Alcohol." 7. Mr. E. J. Parry, "Note on Oil of Male Fern." 8. Mr. E. H. Miller, "The Composition of Australian (Victoria) Milk," "The Composition of Sweetened Condensed Milk," "The Aldehyde Figure of Butter."

Journal of the Royal Society of Arts.

No. 3,081. VOL. LX.

FRIDAY, DECEMBER 8, 1911.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, DECEMBER 11th, 8 p.m. (Cantor Lecture.) Professor VIVIAN B. LEWES, "The Carbonisation of Coal." (Lecture III.)

WEDNESDAY, DECEMBER 13th, 8 p.m. (Ordinary Meeting.) W. YORATH LEWIS, M.Am.Soc. M.E., A.M.I.Mech.E., A.M.I.E.E., "Continuous Service in Passenger Transportation."

THURSDAY, DECEMBER 14th, 4.30 p.m. (Indian Section.) J. TRAVIS JENKINS, Ph.D., D.Sc., Superintendent of the Lancashire and Western Sea Fisheries, "Fisheries of Bengal." SIR STEUART COLVIN BAYLEY, G.C.S.I., C.I.E., will preside.

Further details of the Society's meetings will be found at the end of this number.

CANTOR LECTURES ON "THE CARBONISATION OF COAL."

On Monday evening, December 4th, Professor VIVIAN B. LEWES delivered the second lecture of his course on "The Carbonisation of Coal."

The lectures will be published in the *Journal* during the Christmas recess.

JUVENILE LECTURES.

The usual short course of lectures adapted for a juvenile audience will be delivered on Wednesday afternoons, January 3rd and 10th, at 5 o'clock, by CHARLES VERNON BOYS, F.R.S., on "Soap Bubbles." (For Syllabus, see p. 102.)

Each Member is entitled to a ticket admitting two children and an adult.

A sufficient number of tickets to fill the room will be issued to Members in the order in which applications are received.

Members who require tickets for the course are requested to apply for them at once.

THE INVENTIONS OF JOHN KAY (1704–1770).

By SIR HENRY TRUEMAN WOOD, M.A.,
Secretary of the Society.

Looking through some old papers in search of materials for the history of the Society upon which I am now at work, I was fortunate enough to find some original letters of John Kay, the celebrated inventor, who, after starting a revolution in the textile industry of the world by his invention of the fly-shuttle, died a pauper—it is not known where, but it is believed in France—about 1770, the exact date being quite uncertain.

Besides Kay's letters, which are of special interest, because no specimen even of his signature was hitherto known to exist, there are also letters from his two sons, Robert and William, and a printed document evidently prepared in support of the claims of John and Robert Kay to recognition on account of their inventions, and giving some fresh information about those inventions, together with some interesting details about John Kay himself.

These documents extend over a period from 1764 to 1774. The earlier papers deal with John Kay's invention of the fly-shuttle, and Robert's improvements upon it, including his drop-box. Those of later date refer to John's invention of the machine for making wire cards, and the improvement upon it made by his son William. They all seem to me well worth printing at full length, and I have, therefore, arranged them for publication, together with some extracts from the various minutes of the Society, which I think will serve to make public for the first time the relations which the Kays had with the Society. They do not, indeed, add very much to the meagre amount of information we possess about the great inventor, but they do add a little, and even that little is well worth recording.

The best account of Kay's life is to be found in Bennet Woodcroft's "Brief Biographies of

Hosted by Google

Inventors of Machines for the Manufacture of Textile Fabrics," published in 1863. Woodcroft, after some experience as a patent agent, became Professor of Machinery at University College, London, and when the Patent Office was reformed under the Act of 1852, he became first Superintendent of Patent Specifications, and afterwards head of the office, under the title of Clerk to the Commissioners of Patents. He died in 1879. I myself served under him as a clerk in the office for a short time (1870–71), and owed a great deal to his kindly help after I left the office to undertake other work (the greater part of which, indeed, was placed in my hands by himself). He was an enthusiast in all that related to the history of invention, and an ardent collector of everything connected with inventors. He formed the Patent Office Museum, afterwards developed into the engineering branch of the Science Collection at South Kensington, and it is due to him that most of the old machines now in that collection were rescued from the scrap-heap and preserved for posterity. His short life of Kay has provided the material for subsequent biographers. Espinasse includes Kay in his popular "Lancashire Worthies" (1874), but his very readable history includes nothing which Woodcroft had not already printed. The life of Kay by Mr. R. B. Prosser, in the "Dictionary of National Biography," is, like all that careful writer's work, excellent, and if he has not added much to Woodcroft, those who know Mr. Prosser's capacity for painstaking and minute research will realise that there was not much to add. A recent life of Kay, by John Lord, was published at Rochdale in 1903. The author has succeeded in collecting from local sources a great deal of information about Kay's family, and he has shown conclusively that some of Woodcroft's statements are based on inaccurate information; but he has not been able to find anything new about the man himself, except that he has verified the date of his birth (1704), which was before uncertain.

Kay was a prolific inventor. He took out four patents—the first in 1730 and the last in 1745. To none of these patents is any specification appended, though in most of the grants some sort of incomplete description of the invention patented is embodied. The proviso that the grantee of a patent should file a description of his invention was not always included in the terms of the grant at the time of Kay's patent, and when it was inserted it was not always fulfilled. It was in 1733 that he took out the patent for his epoch-making invention of the fly-shuttle, which is, in the opinion of Kay's biographers, and indeed of all experts, the most important improvement ever made in the loom. Before Kay's invention the weaver had to use both hands, throwing his shuttle from one and catching it in the other alternately, or in fabrics which were too wide for the arms of one man to stretch across (broad-cloths) two men had to be employed, one on each side. In Kay's device the shuttle is thrown and caught by a "picker" on each side, and the "pickers" are worked by a cord from each, passing to a short lever held in the weaver's right hand. He is thus able to jerk the shuttle to and fro by the movement of one hand, while the other is left free for the purpose of beating or closing up the weft. The amount of work was doubled, the cloth was of better quality and the labour was diminished. In Woodcroft's words: "Kay's improvements in machinery for weaving continue in use to the present time; they form a part of each loom actuated by power, of which there are tens of thousands in this kingdom alone forming cloths of silk, cotton, linen, and woollen. He was the founder of the first great improvements in the manufacture of cloth, by which employment is now given to hundreds of thousands of people and to millions of pounds sterling." It may be added that Kay's invention rendered possible the construction of the power loom, the great difficulty having been to devise some mechanical means for throwing the shuttle, in substitution for the human hand.

In the cloth trade the shuttle came into immediate employment, but though the weavers were ready enough to use it, they demurred to pay for its use. The woollen manufacturers of Yorkshire formed themselves into an association called "The Shuttle Club," the object of which was to steal the invention and to defraud the inventor of his legitimate rights by defending actions for infringement. This laudable association was eminently successful, for it succeeded in ruining Kay, while making full use of his invention. The employers were well backed up by their workmen, who broke into Kay's house, destroyed its contents, and only failed in killing Kay himself.

Kay was by trade originally a reed-maker, and he is credited with the first idea of substituting wire for the thin strips of cane or reed from which the "reeds" took their name. They may be regarded as the teeth of the comb or grating, in the interstices of which the threads of the warp pass, so that by the swinging of the frame in which the reeds are set, each successive

Hosted by Google

thread of the weft is pressed into its place between the warp threads, and the whole fabric rendered close and compact.

The use of wire for reeds is believed to have been his earliest invention. It was not patented. Of his numerous other inventions, some patented and some not, few appear to have been of any value. Only two seem to have been of importance—his fly-shuttle and his machine for making cards for carding wool and other textile fibres.

THE "WHEEL-SHUTTLE."

We may now proceed to consider the papers relating to improvements in weaving appliances by John and Robert Kay.

In the minutes of the meeting of the Committee on Correspondence, held February 6th, 1764, we find the entry: "A letter from Mr. Robt. Kay concerning an improvement on the wheel-shuttle. Resolved that it be referred to the Committee of Mechanics." In the minutes of the Committee of Mechanics for April 19th, 1764, the following minute occurs:—

"Took into consideration the reference to this Committee from the Committee of Correspondence of April 6th* of Mr. Robert Kay's improvement of the Wheel Shuttle. It was Resolved that Mr. Kay's shuttle should be tried, and that Mr. Thomas Moore of Chiswick Street be requested to make a tryal of it."

Mr. Moore was a carpet manufacturer, and he received in 1757 the first prize of those offered by the Society for "making carpets in England on the principle of Turkey carpets." He does not seem to have made any report —at least, I cannot find any—and Kay wrote again to the Society a letter, which is referred to in the minutes of the ordinary meeting of September 19th, 1764, where it is stated that a letter from Robert Kay on the wheel-shuttle was referred to the Committee of Manufactures. (The functions of the two Committees, Mechanics and Manufactures, seem to have been rather mixed together.)

In the minutes of the Committee of Manufactures of December 4th, 1764, it is stated:—

"A letter from Robt. Kay, of Bury, Lancashire, was read concerning his Wheel Shuttle, which was delivered by the Committee to Mr. Thomas Moore for tryal, desiring to be informed what had been done with regard to it. Resolved that the Secretary write to him to acquaint him that the Committee do not know any person who understands the manner of using his Shuttle, and to desire him to give the fullest instructions concerning it."*

A letter to this effect was evidently written by the secretary, Dr. Templeman, and here is Robert Kay's reply:—

Bury, Lancashire.
Decr 8th, 1764.

SIR,—Yours of the 4th inst. I rec'd, in answer I very much question whether or no the Committee will be able by any instructions that can be given by Letter to try the utility of the Wheel Shuttle, for notwithstanding the simplicity thereof it may be missed by a Person unacquainted therewith, not only so, but it requires some little practice before a person unacquainted with the Wheel Shuttle can weave so as to shew the advantage of the Wheel Shuttle in its true light, for want of which the Wheel Shuttle might not be so well thought of as it deserves and might be an hindrance to the Wheel Shuttle being made use of in several Branches in which it wou'd be of real service, and which I doubt not wou'd be contrary to the Intent of the Society.

It is through the above considerations that I wou'd hereby propose to the Committee whether or no it wou'd not be best to have the Brass Wheel Shuttle try'd in Bolton where great numbers of wood Wheel Shuttles are used in several Branches of the Cotton Manufacture from half-yard wide upwards and from whence the Committee might have a report made concerning the utility of the brass Wheel Shuttle, attested by such persons in Bolton or may be in Manchester, as the Committee shou'd chuse, after which the Slay or Lathe (being the only part of the Loom which undergoes any alteration) with the Fixtures and shuttle as it was when Wove with might be sent up to the Society for their Inspection and to serve as a Pattern to any one who might think proper to use the Wheel Shuttle.

If the above proposal be agreable to the Committee shou'd be glad to have the Brass Shuttle sent down and will sett about it, if not shou'd be glad of a line from you and will give the fullest Instructions in my Power relative to fixing the Wheel Shuttle for weaving, and am

Yr. h'ble. Sert.
ROBT. KAY.

This letter is preserved in one of the Society's old guard-books, into which were pasted a selection of the letters which appeared worth preservation, and a vast number of miscellaneous documents relating to the Society's operations.

* There is something wrong about this date, for the meeting of April 6th was an ordinary meeting of the Society, not a committee meeting, and the minutes contain no reference to Kay's letter. However, this is unimportant.

* It has always been known that an application had been made to the Society by, or on behalf of, Kay, and Woodcroft printed extracts from the minutes of April 19th and December 4th. He, however, thought that one of the letters was from John Kay, and did not realise that any more was involved than the original invention of 1733.

Hosted by Google

Not infrequently, when a communication was received which a committee obviously considered unfit for any other treatment, it was resolved that the correspondent be thanked, and his letter "preserved in the guard-book." These books consequently contain a great many papers of interest and a huge mass of rubbish, which, if it has become venerable by age, has gained no fresh value by its preservation for a century and a half. There are twenty-seven of the volumes, for the period from 1754 to the year 1782, when the Society began to publish *Transactions*, and it may, therefore, be realised that a search through their contents is a task requiring some courage and a good deal of perseverance.

In the same book are also the two letters from John Kay printed at the end of this article (page 81), and the statement headed "Some Considerations on the Improvement of Weaving Chequer'd and Strip'd Goods," printed on page 83.

The contents of the guard-books are not in strict chronological order, but papers of about the same date are nearly always close together, and they seem to have been pasted in the books as they were dealt with by the various committees. It may, therefore, be taken as quite certain that John Kay's letters and the "Considerations," etc., were received by the Society about the same time as Robert's letter of December 8th, 1764. They do not bear any date themselves, or any indication of a date or address. The only suggestion of a date is that John Kay refers to his invention of a tape loom as made "twenty-two years ago." This was patented in May, 1745, and may well have been invented two years before it was patented.

John's letters give no information whatever about his famous invention, and it is not very obvious why they were sent to the Society; but the writer was then old and very poor, and doubtless he hoped for some grant to be made him on account of one or other of the inventions he describes. They are evidently not in his own writing, and apparently not in that of Robert; but he signed both the letters, and also the two enclosures in the second letter, and the discovery of four autographs of the inventor of the fly-shuttle, when, so far as I have been able to ascertain, none was known to exist, ought to appeal to all who are interested in the history of invention.

It has always been known that a letter had been addressed to the Society by Kay. A portion of one of his letters—the last paragraph of the first letter—has already been quoted by Woodcroft, and again by Prosser, as having been printed in an anonymous book published in 1780, under the title of "Letters on the Utility and Policy of Employing Machines to Shorten Labour." Mr. Prosser says the records of the Society of Arts do not afford "any corroboration of Kay's communication." Such "corroboration," however, has now been discovered.

The "Considerations" does appear to me to be a document of greater historical value. It gives a certain amount of new information about Kay's original invention, and also, as I shall try to show presently, about his son Robert's own inventions, and it adds a good deal to what has already been recorded about Kay's attempts to obtain in France the recognition and the rewards which his own country refused him. It is apparently drawn up by Robert, who was evidently a better man of business than his father, and also, if the document was entirely his own composition, by no means an unskilful writer. The account of Kay's successful efforts to obtain, at all events, the promise of a pension are interesting, and quite in accord with what is known of the practice of the French Court. It was easy for any applicant who was properly recommended to obtain a grant of a pension from the King, and it was not very difficult to get the grant registered, which was the second step; but when it came to payment, it was quite a different matter, and a great deal of influence was required. So Kay seems to have found, and it was probably the breaking out of the Seven Years' War in 1756 which ruined whatever chances he may have possessed. Ill-luck pursued him on the other side of the Channel as on this. Whether he really went back to France and died there seems more uncertain than ever, but about this there will be a little more to be said later on.

I have been able to find nothing more, either in the guard-books or in the minutes after the receipt of Robert Kay's letter of December 8th, 1764, and there the matter appears to have dropped. No copies of the letters sent out from the Society were preserved, and there is nothing to show whether Robert Kay ever received any reply to his communication. It certainly does not appear to have been formally considered by any Committee, or at all events no record of such consideration can be traced. Nor have I been able to discover in any of the minute books any reference whatever to John Kay's letters, or to the printed memorandum. In fact, the narrative ceases abruptly. That this should be so is a very great pity. The Committee missed a great opportunity of doing honour to the Society

Hosted by Google

by including in the list of those who received its awards the name of one of the greatest of English inventors, that of John Kay, the inventor of the fly-shuttle, the father and founder of the British textile industry.

It has always been assumed that the invention submitted by Kay to the Society was the original invention of the fly-shuttle. This on the face of it was highly improbable, because the Society certainly would not have been likely to have given any prize to an invention thirty years old, and one which appears to have attained in that time but a moderate measure of success. It was also strictly contrary to the Society's regulations to give any prize whatever to a patented invention; and this alone would certainly have been enough to prevent the Committee paying any attention at all to a device which, whatever its merits, it must be remembered was in existence just twenty years before the Society itself was founded.

That, in spite of its great merits, the fly-shuttle was not well known or generally used in 1764 seems certain. Guest and, following him, Baines, in their well-known histories of the cotton trade, both say that the fly-shuttle did not come into use in the cotton trade till about 1760, and before that date it was certainly only in the woollen manufacture (not a London industry) that it had been employed. It was, therefore, natural enough that no weavers could be found in London to work it, and Robert Kay evidently realised this when he suggested that the invention should be tested in Bolton or Manchester, where plenty of workmen could be found who were familiar with its use.

But it appears to be quite clear that the invention brought before the Society was not the original fly or wheel-shuttle of John Kay, but his son Robert's improvements upon it. This is stated in so many words in the minutes of the Committee meeting of April 19th, 1764, which says that the matter referred to them was "Mr. Robert Kay's Improvement of the Wheel-Shuttle." From the "Considerations" it appears that these improvements were intended to adapt the shuttle to the weaving of striped or chequered fabrics, and it is added that the stripes were not lengthwise, in the direction of the warp, but crosswise in the direction of the weft (obviously for a chequer pattern the warp also would consist of yarn of different colours arranged in strips). Now this was the object of Robert Kay's invention of the drop-box (brought out about 1760), a device by which the weaver could bring into use any one of three different shuttles, each containing a different coloured weft. This drop-box of Robert's is always stated to be the first device for weaving cross-striped fabrics conveniently, without stopping the loom to change the shuttle, or to re-charge it with a different coloured weft, and if it be permissible for one who is without expert knowledge to express a very positive opinion on such a subject, I may say that it appears to me certain that Robert Kay's "Improvements on the Wheel-Shuttle" consisted of the addition of his own drop-box to his father's fly-shuttle, and that this is the only theory which satisfies all the statements made in the papers brought before the Society's Committee and now first published. There may also have been other alterations; indeed, Robert says that the new shuttles are to be made of metal—brass or iron—instead of wood.

Robert also refers in the "Considerations" to his invention for weaving two pieces of narrow goods simultaneously. This he does not describe. It may have been a device similar to that embodied later in the "tape-looms" or "riband looms," used in Coventry and elsewhere.

There can, I think, be no doubt that the appliance called a "wheel-shuttle" by the Kays was that now known as the "fly-shuttle." The last name never seems to have been used by the inventors. The anonymous author of the pamphlet previously mentioned, "Letters on the Utility and Policy of Employing Machines to Shorten Labour," published in 1780, who seems to have known Kay, or, at all events, to have known a good deal about him, speaks of the wheel-shuttle, and the first recorded use of the term "fly-shuttle" is by Dr. John Aikin, in his book on Manchester (p. 300), published in 1795.* The same writer, in another passage (p. 267), uses the phrase "wheel or flying shuttle." It is possible that the word, like so many technical terms, was originally invented or used by the workmen, and did not for a long time get into print. Kay's original shuttle certainly had wheels, as is shown by the description in his patent of 1733, for although no actual specification was enrolled, the letters patent contain a general description of his invention. The shuttle was stated to be:—

"For the better and more exact weaving of broad cloths, broad bays [baize], sail cloths, or any other broad goods, woollen or linnen, which shuttle is much lighter than the former, and by running on four wheels moves over the lower side of the webb or spring, on a board about nine feet long,

* Murray's Dictionary *s.v.*

Hosted by Google

put under the same and fastened to the layer, and which new contrived shuttle, by the two wooden tenders, invented for that purpose and hung to the layer, and a small cord commanded by the hand of the weaver, the weaver sitting in the middle of the loom, with great ease and expedition by a small pull at the cord casts or moves the said new invented shuttle from side to side at pleasure, and also strikes the layer by his pulling it in the middle uniformly over the piece, makeing it unavoidably even and much truer and better than by any method heretofore used."

It may be that the inventor himself regarded the application of wheels to the shuttle as more important than the device for actuating the shuttle, and hence the name by which he refers to the invention. I have not myself sufficient knowledge of the highly technical subject of weaving to speak definitely about any modern appliances, but I am informed that though wheel-shuttles are sometimes used for weaving heavy goods, ordinary shuttles are not fitted with wheels or friction rollers.

The Wire-Card Machine.

We now come to Kay's machine for making wire cards, upon the history of which also some new and fresh light is thrown by the Society's records.

The preparation of wool for spinning was at the time all done by hand, as it is even now to a very limited extent in the domestic production of genuine homespun goods. The carding engine, though machines for the purpose had been proposed by Bourn in 1748, and by Paul a little later, was really first introduced by Arkwright in 1775, and improved by him ten years afterwards.

The hand cards used may be described as stiff wire brushes. The wires are fixed in a tough leather backing, which is supported by a further backing of wood. Two of them are employed in the process of carding, the lock of wool being laid upon one and combed out with the other. The result is to straighten out the fibres—a process required in all materials used for the manufacture of textiles, except silk, which is produced as a natural thread. The sliver produced by the action of carding is ready for the spinner, who spins it into a thread.

The object of Kay's invention was to facilitate the production of these cards. There is in the engineering collection belonging to the Victoria and Albert Museum what is believed to be an original example of Kay's machine. The history of this particular machine is a little obscure, and it is not known whether it was one of John Kay's machines or an improved machine constructed at a later date. From the evidence now available, it seems hardly questionable that it is really a later form, for it is to be noted that in it the whole process is carried out in one machine, whereas Kay himself says in his description, quoted below, that he used two "engines," one to make the necessary perforations in the leather for holding the wires, and the second to cut the wires to the requisite length and to bend them so that they are securely held in position. The remainder of the work, the fitting of the wires in place, was to be done by hand. The catalogue of the South Kensington collection gives a very clear description of the machine, but it does not all correspond with the account given by John Kay, or with that given by his son William.

It does, however, agree with the account of Kay's machine given in "A Description of the Country from thirty to forty miles round Manchester," by J. Aikin, M.D. (1795), p. 267. Here it is to be noted that the invention is attributed to Robert Kay. If Robert improved his father's machine, it seems likely that the South Kensington example may be one of Robert's machines, in which case it is nearly as interesting and valuable as if it had been the actual apparatus of John Kay himself. The following is the passage in which the machine is described; it occurs in that part of the volume devoted to Bury:—

"The inventions and improvements here in different branches are astonishing. One of the most remarkable is a machine made by Mr. Robert Kay, son to the late Mr. John Kay, inventor of the wheel or flying shuttle, for making several cards at once to card cotton or wool. The engine straightens wire out of the ring, cuts it in lengths, staples it, crooks it into teeth, pricks the holes in the leather, puts the teeth in, row after row, till the cards are finished; all which it does at one operation of the machine, in an easy and expeditious manner, by a person turning a shaft, and touching neither the wire nor the leather."

The catalogue also gives 1750 as the date of the invention by Kay, and adds that card-making machines did not come into use until fifty years later, when they were introduced in an improved form by Amos Whittmore.

In November, 1765, the following letter from John Kay was received by the Society:—

Gentlemen,—I have observed that the only method to make good woolling and cotton goods is by the wooll and cotton being well carded for the spinner and without that the goods cannot be well manufactured.

Hosted by Google

I have for a long time taken notice that the present method of making of woolling and cotton cards is attended with great difficulty and expence and but few of the Cardmaker's that makes the cards to that perfection as are fit to be made use of, and the method they make them in, is, very slow, which makes the price of cards very high, so that they often make use of them too long, which breacks the stable of the wooll and the cloth, and cotton, are much damag'd for that reason.

Now I have invented and made two Engines which I have for a long time experimented for makeing of woolling and cotton cards, the one for pricking the leather's and the other to cut and bend the wires that is to be put into the leather's, now pricking the leather's and making the wires is all the diffeculty and teadous work in card making: the rest is children's work or may be done by any hand, and children of twelve or fourteen year's of age is more proper to work these Engines that I have made then grone up person's so by this method it is unnecessary to be at much expence of men's laber; and by these Engines as much work may be done by one person in one day, as in the method heather to precticed can be done by one person in twelve days and to that degree of perfection as cannot be done in the preasent method so that if these Engines was to be put forward, they would be of great advantage to the woolling and cotton factorys in this Kingdom for the reasons above mention'd.

from your humble servant

John Kay

In the Talbot Inn Yard in the Borough Southwark
Novr. 27, 1765.

The original of this has fortunately been preserved. Like Kay's other letters, it does not seem to be in his own writing, but it is signed by him. It is endorsed on the back as "Referred November 27th, 1765."

This letter was considered at a meeting of the Committee of Manufactures held on January 7th, 1766, the following being the minute relating to it:—

"Took into consideration Mr. John Kay's Engines for making Woollen and Cotton Cards.

Mr. Kay's letter was read, Mr. Kay attended, and his Engine for cutting, doubling, and crooking Cardmakers Ware [? wire] was produced and worked.

The Committee inspected the Pricking Engine in the Machine Room.

Adjourned to Thursday next at 6 to consider further Mr. Kay's Engines."

From this it is quite clear that Kay used two separate machines, and that the two machines were shown to and tested by the Committee. It should be remembered that the Society was then occupying the house opposite Beaufort Buildings, in the Strand. The machine-room referred to was the large room on the ground floor in which the collection of models and machines was preserved.

The consideration of Kay's apparatus was taken up again at a meeting of the Committee, held two days later, on January 9th, 1766, as recorded in the following minute:—

"Resumed the consideration of Mr. Kay's Engines.

Mr. Kay attended and answered such questions as were put to him.

Resolved it is the opinion of this Committee that the Machines produced by Mr. Kay for cutting, doubling, and crooking the wire and for pricking the leaves of cards for the use of the Woollen and Cotton Manufactures are very ingenious, and well contrived for facilitating that branch of business.

Resolved that six pair of Cards be made from wires crooked and leaves pricked by Mr. Kay's machines, in order to enable the Committee to ascertain the merit of those Engines, and that Two Guineas be advanced Mr. Kay towards his furnishing the wires and leaves."

There is also a note in the minutes of the Committee of Correspondence of January 6th, 1766, that:—

"A letter signed John Kay, without date, concerning a loom was read. Ordered to be referred to the Committee on Manufactures."

There is nothing to show what this letter was really about, or whether it was ever dealt with. It has not, so far as I can find, been preserved. It may have contained further details about his wire-card machine, or it may have referred to some other of Kay's numerous inventions.

I have been unable to find any record of any further correspondence with Kay, or any further evidence that the Committee had the machine before them again. Whether Kay made the cards or took any further action in the matter seems absolutely uncertain. From this date the Society's records yield no further information about him. Indeed, this is the latest known reference to Kay in existence, and it has this peculiar value—that it shows him to have been living in 1766, a fact of which there was no previous proof, though he is believed, on very slight evidence, to have gone a second time to France and to have died there.

Eight years later, after Kay himself was dead, we again find his machine coming before this Society, and the way this was brought about is not a little curious.

On June 7th, 1774, the following letter was

Hosted by Google

received from Mr. Nathan Fielding, of Boston, New England:—

Boston, New England,
April 27, 1774.

SIR,—I hope your goodness will pardon me for troubling you with a Letter, as I always accknowledge it my Duty to be of service (when in my power) to every one that study the Arts and Siences, and I knowing that your Great and worthy Society always give Due encouragement to all Ingenuity, have taken the Liberty to send you a few lines, to accquaint you that I am now at Boston, New England. I have had the pleasure of meeting with one Mr. Joseph Pope a very Ingenious man, he has invented a Machine for cutting and crooking wire for card's teeth, which any boy of 10 years old, with this Instrument will, Cut, Staple and crook 10lb. wt per Day with ease, . . . the Machine is so simple a construction that I wonder it has not been long in use, (as I cannot remember ever hearing of any such thing) besides of Little cost according to its merit and will do of all sorts of teeth from the finest to the coarsest, and if that none have apply'd to you About any such thing I hope that the said Mr. Pope will meet with ample satisfaction for his trouble.

I humbly beg you will give the said Mr. Jh Pope an Answer to this Letter and Direct to him, Clockmaker Southend Boston, New England, and I shall always accknowledge it the greatest favour Done to your humble Servant

NATHAN FIELDING.

Mr. Fielding was not a member of the Society. This letter was referred to the Committee of Mechanics, and it was brought up at a meeting of this Committee on October 27th, 1774. It was then postponed for consideration to the next meeting. This next meeting of the Committee was held on November 3rd, 1774, when we find the following minute:—

"Resumed the consideration of the letter on a machine for making cards for wool and cotton.

Mr. Kay attended, and informed the Committee that he had used a machine upwards of ten years for this purpose invented by his father by which he can cut double and crook fifteen pounds p. day.

The Committee examined the Minutes of the Committee of Manufactures dated January 7th and January 9th, 1766, on Mr. Kay's machine.

Resolved that Mr. Fielding be informed that Mr. Pope's Card Engine is not new and that a much better machine for that purpose was offered to the Society many years since.

Resolved it is the opinion of the Committee that the Society proceed no further in this business."

It may be assumed that the Mr. Kay mentioned was invited to attend the Committee in consequence of his knowledge of the subject, as was the usual practice at the time. On November 9th, 1774, the following letter was received from him, and it appears from it that he was William Kay, the youngest son of John.*

SIR,—The countenance I receiv'd from the Committee on wednesday evening Last, & my not being aquainted with the form of a regular Petition & that Glossy Language which adds Great Lustre to Truth & is very necessary to cover the face of Fiction, I Presume without any prelude or form, to aquaint you with they Following facts, praying you to Lay them before they honourable Committtee.

I being the only person that has work'd & made Publick the Engine for Cutting doubleing & crookening of wire for wooll & cotton cards, & also the Engine for Pricking the Leathers, the original & first Idea I acknowledged to be the Invention of my Father (Jno. Kay) but from my Constant working them for upwards of eight years, I have found, and made several Improvements which renders them to work much Quicker, & more Perfect, & I flatter myself I have a few at work in great perfection, the advantage gain'd by these two Engines is more then six to one beside their superiority in the work . . . . Cards by the help of these Engines cannot be made otherwise then True and every Tooth even, & of the same length; which is impossible to make the old way, & when they are not even but one tooth Longer then another, they break the Staple of the wooll which is a Great prejudice to Cloth.

If I am honour'd with a call to attend they Committee I shall Take pleasure in ascertaining what I have advanced, to their general Satisfaction, Should they then View the advantage in the same Light I do, & favour me with their sanction & Encouragement I will too the utmost of my ability & power Vend & Publish them for the general Utility & Benefit of the Community & am Sir yr. most obt. & hble.

Servt. WM. KAY
No. 11 Tooley Street
9th *November* 1774.

This letter was considered at a meeting of the Committee held on December 1st, 1774. The record about it runs as follows:—

"Took into consideration the letter from Mr. Kay on a Machine for Making Cards for Wool and Cotton.

Read the letter, and Mr. Kay attending was called in and says that the Improvement he has made in the Machine makes it ½ value more than his fathers.

That his machine is adapted to prikh the twill way i.e. the lines in which the wires are fixed are prickt diagonally, by this means the Wool is cleared of any lumps and made fine and levell for Spinning.

* According to Lord's Memoir (p. 135), William was born in 1765, but this must be incorrect. He is also stated to have died in 1783.

Hosted by Google

Mr. Kay being ask'd wether he would produce his Machine to the Committee at their next meeting for their inspection

Answer'd He would.

Postponed the further consideration."

The Committee met again on December 8th, 1774, and

"Resumed the consideration of the Machine for cutting, doubling, and crooking wires for cards for wool and cotton postponed at the last meeting.

Mr. Kay attended and worked the engine in presence of the Committee as also his engine for pricking the leathers.

Mr. Kay being asked what improvements he had made since the machines were produced to the Committee in the year 1766,

Answered that he has invented the scrip and twill way for pricking the leaves which are the only ways for wool and cotton.

Being asked who first invented this kind of machines,

Answered his father John Kay.

Was this business done by hand before his father's invention,

Answered, Yes always, and he never knew of any machine.

Whether his father ever brought it so far in use as to make cards for sale—Answered, Never.

Did he himself ever make cards for sale by his Engine—Answered, Yes.

Says he has reduced the price of cards on an average 30 per cent., and that this reduction is owing to the engine, for the materials are much advanced in price.

Mr. Kay says that his engine is made chiefly of iron and steel, and that he now hangs by treddles the weights which steady the work by which the machine is kept in constant order, whether working quick or slow, whereas his father's engine being made principally of wood, and the weights not being properly hung, was liable to be out of order and make the work irregular.

Ordered that Mr. Cook, Rug Maker, in Black Lyon Yard, Whitechapple, be wrote to and desired to attend the Committee at their next meeting, if convenient, or inform the Committee by letter whether he makes use of cards made by Mr. Kay, whether he thinks them equal or superior to cards made in the old way, and how much the price of cards has been reduced by this machine.*

Postponed the further consideration."

The matter was finally dealt with at the meeting on December 15th, 1774, as follows:—

"Resumed the consideration of Mr. Kay's Machine for making Cards for Wool and Cotton.

Mr. Cook attending according to the request of the Committee at their last meeting inform'd the Committee that Mr. Kays Cards are better for his Use and made more true than any other. That they are cheaper as he now buys for 2/6 what is still sold by other Cardmakers at 3/ and what he used to give 3/6 and 4/ for.

What is Mr. Cook's opinion of the Cause of this Reduction of the price of Cards

Answer'd, He believes it to be owing to the Contrivance of the Machine by which they are made Quicker and more true.

Being ask'd, Whether the Staple of the Wool is better preserved by Mr. Kay's Cards than any other

Answer'd, A great Deal for Mr. Kay's Cards draw it out to its full Length whereas the others frequently break it.

The thanks of the Committee were returned to Mr. Cook for his obliging Attendance on the Committee.

Resolved it appears to the Committee from the Inspection of the Machine when at work and from the Information of Mr. Cook given to the Committee this Evening that the Invention is a Matter of Great Utility to the Public.

Resolved to recommend to the Society to give a Bounty of Fifty Guineas to Mr. Kay."

This resolution was confirmed by the Society, and the award is recorded in the Register of Premiums and Bounties published in 1778. It is also included in Dossie's list ("Memoirs of Agriculture," Vol. III. p. 458), but in that list the name is erroneously given as Ray. It is very likely in consequence of this misprint that no mention, so far as I can find, has ever been made of an award being given by the Society for Kay's machine for making wire cards, since Dossie's lists were always regarded as official, and he had the general authority of the Society for the papers he published, if not their express sanction for the lists of awards.

In conclusion, I may point out that the way in which William Kay refers to his father seems to indicate that he had been dead for some little time. This fact, and the fact that he was alive and in London in 1766, render it extremely probable that he died not much before or much after 1770.

APPENDIX.

I.—Letters from John Kay—(Probable date December, 1764).

(No. 1.)

Gentlemen,—Twenty-two years ago by the desire of Mr. Joseph Stell, of Keighley in Yorkshire, I invented for his tape lomes to weave by water which Mr. Stell had a patent for which was got in my name because Mr. Stell could not make oath that he invented it; there is one of these Engines at work by water near Manchester by the permission of Mr. Stell, since these Engines as been at work I have made a great improvement in the said Engine by model.

* Cook was not a member of the Society.

Also there is a invention for spining of cotton by water, but as the Engines was very expencif to make and keep in repair so that the profit by this invention is very little; now I have contrived to lay by most of the great expence of making and repairing the Engine and to perform with more ease and in a simpler manner and the yarn much better.

I have great many more inventions then what I have given in and the reason that I have not put them forward is that twenty years ago by the bad treatment that I had from woolling and cotton factres in different parts of England and then I apply'd to Parlement and they would not assist me in my affairs which obliged me to go abroad to get money to pay my debts and support my family.

from your humble servant
John Kay.

(No. 2.)

Gentlemen,—the other day I was taking notice of the drill plough which I think is very imperfect in several partes which I can improve very much; also I can make a good improvement in the plough that plough's sowes and cover's at once; likewise a good improvement in the two handed wheel for spining wool but the method will not be of any servis in spining of lining cotton and silk; likewise a plough may be made practiable to cut drean's in marshe land and in makeing canals or sluses for navigation as Duke of Bridgwaters cut near Manchester; it is my opinion that two men and four horses with a common plough whould plough up as much soil clay or gravel as twenty four men whould dig up in the time and while the men are throwing it out the plough might be at work at a little distence from they men; by shuch a method great expences might be saved in great undertakeings and the navigation finish'd in much less time.

from your humble servant,

John Kay

Enclosures with No. 2.

A method to regulate fire to anne degree of heat which will be valuble for distilling, chymistry, making of steel, pressing of woollen goods, and green houses.

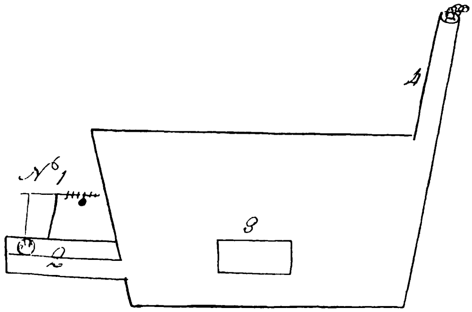
In distilling sometimes the fire rises so high which causes the spirit to blow the top of the still of which sets fire to the house which is often to be seen in the nuse papers.

The chymisters by there fire being to hoot causes there glases to brack which makes there loss considerable.

In makeing of steel it is by keeping a furnace to certain heat wherein the Iron is lad in; for a bout three days and three nights. If the furnace is a little to hoot it melts the Iron which makes the loss great, and if the furnace is not to such a degree of heat the steel is not good.

In pressing of woollen goods if the fire under there pleat be not a certain degree of heat the cloths or stufes are not well pressed and then the are not fit for seal, and if the fire rises a little to high the goods are often burn'd.

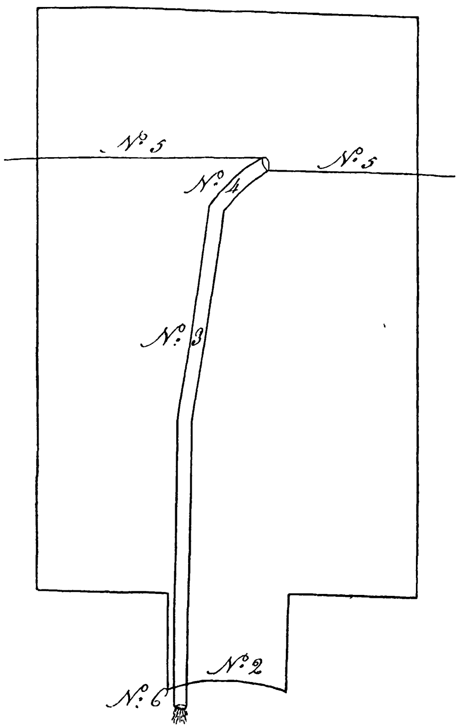
And in the green houses they chowse them to one degree of heat.



No. 1—Regulator. No. 2—A pipe to furnish the draft with hare. No. 3—The door to put the cole in. No. 4—The draft pipe.

If the Committee of Michinicks do not understand my drawing I am redy to explain to anne of them by words; the method is simple and will prevent the misfortens before mentioned.

from your humble servant
John Kay.



Hosted by Google

A method to clean docks for Shiping; No 1 is supos'd to be the dock; No. 2 the gates; No. 3 a pipe of wood six inches wide and the sides dresed to half a inch for lightness; that parte which is No. 4 is made of leader with Iron hoops to keep it open; No. 5 is a rope by which a man on each side the dock pules No. 3 from one side of the dock to the other; the nose of No. 4 is keept down to the mud by a weight then the piller of water that lyes a bove forces the mud into the pipe which runs out at No. 6.

Several other articles is belonging which cannot well be explain'd but by words; the method is simple with little expence and much wanted.

from your humble servant,

JOHN KAY.

II.—SOME CONSIDERATIONS ON THE IMPROVEMENT OF WEAVING CHEQUER'D AND STRIP'D GOODS.

Whereas by a Wheel Shuttle, invented by *John Kay*, late of *Bury*, in *Lancashire*, great Advantages have arisen to the Publick, by Means of broad and narrow Goods, not strip'd in the Weft, being wove in a more easy and expeditious Manner, than heretofore practised; some of the particular Advantages of which, in the Cotton Manufacture, are underneath set forth, by which it may be understood, what Advantages may arise to Chequer'd and strip'd Goods, by the Wheel Shuttles being used therein.

1st, In Cotton Goods of Half Ell wide, it's found by Experience, that a Weaver may gain fourteen pence by the Use of the Wheel Shuttle, as soon as One Shilling by the Use of the Hand Shuttle; and in Yard-wide Drawboys, Indian Jeans, &c., it's likewise found by Experience that a Weaver may, by the Use of the Wheel Shuttle, gain sixteen pence, as soon as One Shilling by the Use of the Hand Shuttle, for the following Reasons: The Spool, Pin, or Quill (upon which the Weft is Wound) used in the Wheel Shuttle, will contain five Times as much Weft as the Spool, Pin, or Quill, used in the old Way in the Hand Shuttle, by which Means there's not the Necessity of stopping the Loom so often by four Times, when the Wheel Shuttle is in Use, as in the old Way when the Hand Shuttle is in Use, and consequently not so much Time lost; likewise the Cloth must infallibly be better, by not having so many Pieceings in the Weft; likewise in Goods one Yard wide, the Wheel Shuttle may be throw'd quicker through the Shed; and as a great Number of Weavers cannot throw their Shuttle through the Shed, without frequently striking against the Edges, which is one Reason for slack and bad edges, it is entirely avoided by the Use of the Wheel Shuttle.

2d, Another Advantage arising from the Use of the Wheel Shuttle is, the Weaving with the same is much easier than by the Hand Shuttle, and consequently more Work may be done in the same Time (with the Wheel Shuttle than with the Hand Shuttle) on that Account, and Children may sooner be set to the Loom, and accomplish their Work much better, than by the old Way; for it must be allowed, that as Men, Women, and Children, find themselves tired by their Labour, their Pace abateth; whereas in Labour that is not so tiresome, a Man may better and more chearfully continue the Pace he begun; likewise in all kinds of figur'd Goods where there are a great Number of Tradles, it's difficult to teach Boys to weave the Goods true, their Attention being so divided betwixt the catching of their Shuttle, and the treading of their Tradles, which Difficulty is removed by the Use of the Wheel Shuttle, as their Attention may be mostly confin'd to treading their Figure regularly over, by which Means they will make very few false treads, and young Boys in a very short time, be as capable of performing figur'd Work, as them of riper Years; likewise Persons disordered with Rheumatisms, &c., which has rendered them unable to weave with the Hand Shuttle, have readily and chearfully been enabled to accomplish their Work with the Wheel Shuttle.

3d, Another Advantage arising by the Use of the Wheel Shuttle is, that the Weft may be better laid in the Shed by the Wheel Shuttle, than by the Hand Shuttle, the Hand Shuttles Course through the Shed is Circlewise, the Wheel Shuttles Course being in a right Line, lays the Weft in the Shed in a shorter Course, by Means of which, a Piece of Goods may be wove with less Weft with the Wheel Shuttle, and at the same Time be neater and better, than by that wove with the Hand Shuttle; likewise in Weaving with the Wheel Shuttle, there is not that Necessity of putting the Lathe so far back, as in weaving with the Hand Shuttle, by which Time is saved. There are several Manufacturers in *Bolton*, who from long Experience, have found, and are ready to produce, Draw Boy Goods wove with the Wheel Shuttle with Ten Pounds of Weft, which shall be neater, and take as much or more Money in a Market, as Draw Boy Goods of the same Kind wove with the Hand Shuttle with eleven Pounds of Weft of equal Fineness with the ten Pounds before mentioned. Persons who weave very quick have a Spring to their Leathe, or give it a great Fall, so that the Leathe being pushed from them will fall against the Face of the Cloth, and most Persons who weave quick close their Weft as soon as they can pull out their Shuttle, at the Distance of five or six Inches from the Face of the Cloth, which with the Circular Course of the Hand Shuttle in the Shed, will easily account for the Loss of a great deal of Weft. Silk and Cotton Handkerchiefs look much richer with the same Silk in the Warp, and are neater with three Ounces less Weft in a Dozen of Handkerchiefs, if Foot and Hand go together, than if struck with a Cross Shed, and as the Wheel Shuttle brings the Weft so near the Face of the Cloth, any Kind of Goods may be struck with open Shed, or with Foot and Hand together, without losing any more Time, than if struck with a Cross Shed. And Experience makes it beyond all Doubt that neat light Goods of every Denomination, are much better, by being tread and struck at the same

Hosted by Google

Time, as it lays in the Weft smooth, and leaves it without Ridges in the Work.

4th, Another Advantage arising by the Use of the Wheel Shuttle is, that the Weft comes off from the Spool, Pin, or Quill, nearly of the same tightness from End to End, and may be regulated to come off from the Spool, Pin, or Quill, nearly in what degree of tightness is necessary, for the Benefit of the Cloth and Strength of the Weft at the Weaver's Pleasure: Whereas in the Spool, Pin, or Quill, made Use of with the Hand Shuttle in the Old Way, the Effects are quite different, and excessively irregular; for Instance, when a full Spool, Pin, or Quill, is put into the Hand Shuttle in the Old Way, what with the Weight of the Spool, and the sudden Motion given it by the Weaver throwing the Shuttle into the Shed, the Weft is frequently broke, before the Spool can be put in right Motion, which if it escapes, the Danger is not less, when having passed through the Shed, the sudden Stop put to the Shuttle often causes the Spool to over-run itself, and which at the next throw frequently breaks the Weft, which supposing all happens to go well, and the Weft comes off to near the Bottom of the Spool, then the Stress upon the Weft must be a many Times more, in Proportion, to the Distance of Purchase from the Centre, betwixt a Spool when full, and when near empty, and which, consequently must either break the Weft, or impede the Shuttles Motion in the Shed; and Whereas it must be allow'd, that in all Weaving, it's requisite that the Weft be laid in the Shed in a proper tightness, from which if it deviates, it must be a Fault. It's easy to comprehend, that considering the Difference of Action, between a Spool (in the old Way) when full, as likewise when near empty, that it's impossible the Weft should be (by the old Way) laid in the Shed, any Thing like near what it should be, and which by the Spool, &c. used with the Wheel Shuttle, may be done a great deal better; the regular coming off of the Weft from the Spool used with the Wheel Shuttle, is a Reason why weaker Weft may be wove with the Wheel Shuttle, than with the Hand Shuttle in the old Way. From the Elasticity of Horse Hair, Tufts have been invented, as Springs are put into the Hand Shuttles to hinder the Spool from over-running itself, but have not answered what could have been wished for from them, as the Resistance from the Tufts must vary, as the Spools are full or empty; therefore to make the Resistance more equal, and somewhat like answer the Intention, the Spools must be very small, so that one of the Spools used with the Wheel Shuttle will be equal to eight of the other, which will cause a great Loss of Time in stopping, to supply the Hand Shuttle with Spools seven Times more than that of the Wheel Shuttle, if the Spools for the Hand Shuttle are made of the common Size, as five to one of the Wheel Shuttle the Resistance it meets with from the Tufts, endanger the Weft to break, or the Edge to be drawn in, and if that is carefully avoided, the Weaver must lose Time in Weaving the Upper Part of the Spool very slow; but by the Means of a moveable Eye placed in the Wheel Shuttle, that directs the Weft, it may be so regulated, that the Resistance the Weft meets with in coming off from the Spool (used in the Wheel Shuttle) will be nearly equal, during the emptying of a whole Spool. All Kinds of Irish or Scotch Yarn that is too hard twisted for Weft, may, by the Use of the Wheel Shuttle, be a little untwisted in the Weaving, and so ordered by Means of the moveable Eye in the Shuttle, as to be wove without any Snarls or Curlings in the Weft, and by the same Rule, all Sorts of Weft that are too soft, may be made a little harder, by having the Weft wound on the Spool the contrary Way, which, is easily done, by winding with the Wheel Band cross'd or open.

5th, Another Advantage arising from the Use of the Wheel Shuttle is, that in Weaving with the same, one Hand keeps its Position upon the Lathe Top, the other Hand holds an Handle, by which the Wheel Shuttle is cast through the Shed at Pleasure, which Lathe Top, and Handle, soon becomes warm, and keeps the Hands from being so soon numb'd in Cold Weather; Whereas by the use of the Hand Shuttle, the Weaver much sooner has his Hands numb'd with Cold, by changeably handling the Shuttle, first with one Hand, then the other, as by moving first one Hand, then the other, from the Shuttle to the Lathe Top, it so happens, that when a Weaver has his Hands numb'd with Cold, he frequently lets his Shuttle fall, by making false throws, by which, his Shuttle Points are damag'd, which breaks his Warp, and otherwise much hinders him, the Wheel Shuttle not being so liable to be thrown down, very much facilitates the Quickness of Weaving.

6th, As it appears that it is upon the Wheel Shuttle having the before-mentioned Advantages over the Hand Shuttle, that a Weaver may, in Cotton work of Half Ell wide, gain Fourteen pence with the Wheel Shuttle, as soon as One Shilling (in the same Kind of Goods) with the Hand Shuttle; so likewise it is to be observed, that when Goods are wove broader, the Wheel Shuttle has still a greater Advantage over the Hand Shuttle, so that in Goods wove Yard and Half, or two Yards wide, a Weaver may, with the Wheel Shuttle, weave as much in four Days, as in the same width with the Hand Shuttle in six Days; its likewise to be considered, that in broad Goods, the Weaving with the Hand Shuttle is very painful, and by continually leaning against the Breast Beam, frequently impairs the Persons Health, and is the Occasion of the Death of many; likewise the Weaver being of Necessity obliged continually to have his Arms extended, he cannot have such a powerful Hand or Foot upon his Loom, as is requisite he should have; whereas by the Use of the Wheel Shuttle, the Weaver sits at his Ease, with his Hand upon the Middle of the Lathe Top, and consequently with much more Ease, striketh to the Lathe, uniformly over the Piece; likewise neither Men nor Boys, except of a good Size, are able singly to weave broad Goods with the Hand Shuttle, whereas,

Hosted by Google

by the Use of the Wheel Shuttle, Boys singly, may easily manage the Weaving of Broad Goods, and be much sooner set to the Loom, and in less Time Master of their Business.

7th, Now as it appears by the before-mention'd that the Wheel Shuttle is of great Advantage in weaving of Cotton Goods, both broad and narrow; and whereas great Quantities of Chequer'd and Strip'd Goods are Manufactur'd in this Kingdom, in the Weaving of which the Wheel Shuttle has not heretofore been applied to Advantage, by Reason of the Number and Changing of the Shuttles; and whereas a Method has lately been invented by *Robert Kay*, Son of *John Kay*, Inventor of the Wheel Shuttle, whereby Chequer'd and Strip'd Goods may be wove with the Wheel Shuttles, and be changed at the Will of the Weaver in a much smaller Time than in the common Method now practis'd, and in a Method capable to be understood by one of a slender Capacity. Now, he the said *Robert Kay* presumes, that by the above Invention, the same Advantages at least, which the Wheel Shuttle has over the Hand Shuttle, in weaving of broad and narrow Cotton Goods will likewise be in the weaving of Chequer'd and Strip'd Goods, which Advantages, for want of the above Invention, could not heretofore be had in the Weaving of Chequer'd and Strip'd Goods. Likewise the abovesaid *Robert Kay* has invented a Method, whereby two narrow Pieces of Chequer'd or plain Goods may, in the same easy and expeditious Manner, be wove by one Weaver, at one and the same Time, and the two Pieces better and more regularly selvaged, by which great Advantages may arise to the Publick; which invention of two Pieces of Goods to be wove by one Weaver at one and the same Time, cannot be applied to Advantage, in the weaving of Chequer'd and Strip'd goods, where the Goods are Strip'd in the Weft, but along with the Invention for changing the Shuttles; and as the Manufacturers in this Country are sensible of the Hardships of procuring a sufficient Number of Weavers to weave ten or eleven Nails and 3-4ths of a Yard wide Check, on account of the small Wages got on those Goods (especially in Time of War) by the above Invention of weaving narrow Chequer'd Pieces at once, the above Hardships will not only be removed, but the Weavers will be enabled to weave narrow Goods considerably Cheaper, and at the same Time get more Money, than they can at present in any Kind of Yard wide Check, by means of which the Manufactory will be on a much better footing then formerly, as the worst kind of Goods may be manufactur'd with equal Pleasure as the best Kind, it must have been a great Grievance to the Manufacturers, they having made great Quantities of some Kinds of Goods for which they had no immediate Demand, only to keep their Weavers in good Humour; and as the before-mention'd Invention of Weaving two narrow Pieces of Goods at once, will be of great Advantage in Fustians and other Kinds of Plain narrow Goods, as in Chequer'd and Strip'd Goods, by means of which the Weaver will not only get more Money, and at the same Time weave them Cheaper than heretofore, by which they may be brought cheaper to foreign Markets, which must not only increase the Demand but secure the Trade to ourselves, and give us the Advantage over Foreigners. Likewise the before-mentioned *Robert Kay* has by a Construction of the Wheel Shuttle of Iron, caused the same to be more beneficial than those made of Wood, because the Wheel Shuttle made of Iron will contain a larger Spool than that made of Wood, notwithstanding the length of them be both a like, and the Wheel Shuttle may be made of Iron to any necessary Degree of smallness, and at the same Time run more steady than those made of Wood, by having the Rims of the bottom Wheels further asunder, by which it runs on a larger space; those Wheel Shuttles of Wood cannot be made very small, and at the same Time have a sufficient Weight and Strength, the Iron Wheel Shuttles may be made to any necessary Weight, by which a Weaver may cause its Course through a bad Shed to be more sure, and as it must very much facilitate the quickness of weaving, by always having their Shuttles in good order, those made of Iron will continue very near their original Perfection many Years longer than those made of Wood, those made of Wood, being subject by the alteration of Moisture and Drought, to crack and twist the Shuttle Body which sets the Wheels out of their true Direction, and causes the Shuttle not to run so well, and is an hindrance to the Weaver, which is not the Case with those Shuttles whose Bodies are made of Iron: the Iron Wheel Shuttles will not only be much more advantageous in the weaving of narrow Goods but likewise of very great Advantage in broad heavy Goods, especially in the weaving of Bed Ticks, by Means of which, Bed Ticks may be wove better, and much easier, than in any Method heretofore practised.

As there is no doubt but it will greatly surprise any one who reads the before-mention'd, to think that if the Wheel Shuttle has the Advantages over the Hand Shuttle as is herein set forth, how it comes to pass the Wheel Shuttle has made so small a Progress, in a Country where Trade and Manufactures are of such Importance to every one, from the King down to the Beggar. In Answer, Mr. *John Kay* having invented the Wheel Shuttle, obtained a Patent for the same, thinking thereby to secure to himself in the vending or hiring out the Wheel Shuttles, some Advantage which might serve as a recompence for the Invention, and having set several of the Wheel Shuttles to Work, on broad Woollen Goods, it appeared that one Man would do as much Work, and better with the Wheel Shuttle, as two Men with the Hand Shuttle, upon which the Weavers concluded, that in Consequence as one Man could by the use of the Wheel Shuttle do as much Work, as two Men with the Hand Shuttle, one half the Weavers then employed in the broad Woollen Way must (if the Wheel Shuttle went forward) starve for want of Employment. The Weavers therefore assembled in a Mob, determining to hinder the Wheel Shuttles

Progress, by killing of Mr. *John Kay*, the Inventor, who very narrowly escaped by flight; the Mob went to the Houses where some of the Wheel Shuttles were at Work, and forcibly seized and burned them, and otherwise ill-used the Houses, yet notwithstanding the threats of the Mob, &c. several Manufacturers who lived at a Distance from the Places where the Mobs assembled, being sensible of the Benefit which would arise to them, if they could Manufacture their Goods upon easier Terms than their Neighbours, got the Wheel Shuttles fixed upon Looms in their own Houses; the Weavers on which for the most Part, did all in their Power (by loitering away their Time, and spoiling their Work) to keep their Masters ignorant of the Advantages which attended the Wheel Shuttle; for its to be observed that the Weavers who were good Workmen, and the Weavers who were bad Workmen, where equally bent against the Wheel Shuttle, for the following Reasons. The Weavers who were good Workmen, were afraid, that if the Wheel Shuttle went forward they would stand little better Chance than the Weavers who were bad Workmen, as the facility of the Wheel Shuttle would put them nearer on a par as Workmen, and consequently they would lose their Priviledge, of either having more Wages or in bad Times being constantly employed; on the other Hand, the Weavers who were bad Workmen imagin'd that if the Wheel Shuttle went forward, there would not be Employment for so many Weavers in the broad Woollen Way by one Half, and they conscious of their own Abilities, imagin'd that it must be their Lot to be unemploy'd; but as what is here said is not meant of the whole Body of Weavers, so likewise there were several, who well considering their own Interest, got the Wheel Shuttle, by which they got almost double to what they could by the Hand Shuttle, yet gave the Wheel Shuttle a bad Character, for fear, its general Use might prove to their Disadvantage; yet notwithstanding which, the Advantages of the Wheel Shuttle were so evident, that it every Day gained Ground, and the Inventor Mr. *John Kay*, expended large Sums in furnishing the Weavers with Wheel Shuttles, at the rate of fifteen Shillings a Year, which Rent when due, being demanded, most Part refus'd Payment, which caused Mr. *John Kay* to have recourse to the Law for recovery of his Rights, and was withstood by several of the Weavers, who were supported by Contributions from others, and as Mr. *John Kay* could not with Convenience be engaged in Law with all from whom Money was due, and who denied him Payment, it so happened, that a great many who did not contribute in Money against him, yet, thought proper not to Pay, choosing rather to wait the issue of a Number of Law Suits (well knowing that might overcomes Right) which the Defendants so prolonged that Mr. *John Kay* had spent his all without being able to bring his Affairs to issue, which bad usage caused Mr. *John Kay* to stop giving necessary Directions for setting the Wheel Shuttle to Work, as likewise from communicating any Improvements which generally occur when an Invention comes to be put into Practice. Another Thing which must hinder the Wheel Shuttles Progress was, that when attempted to be set to Work, the Weavers have frequently thrown it up, and fallen to the old Way (whereas a few Words of Instruction would have enabled them to have gone forward very easily) they imagining the fault was in the Wheel Shuttle and not themselves, gave the Wheel Shuttle a bad Character, which has hindered many from attempting it, but as has been before mentioned, Mr. *John Kay* being engaged in several Chancery Suits for the recovery of his Rights, which Suits were so prolonged, that with the Charges thereof, and supplying the Weavers with Shuttles, his all was expended, at which Time he made his case known to several Members of Parliament, thinking either to get a Premium and let his Invention go free, or an Act which would enable him to come at his Rights otherwise than by tedious Chancery Suits, and having waited some Time in Expectations, at length was quite wearied out with Attendance and Dependance, and therefore resolved to apply to the *French*, who upon his arrival at *Paris* ordered him to *Amlui* in *Normandie*, where the Wheel Shuttle was experimented, which gave such Satisfaction, that upon Mr. *John Kay's* coming back to *Paris*, the *French* Ministry made him a Present of fifteen thousand Livres, and the Province of *Languedoc* seven thousand Livres, and granted him a Patent for the sole making and vending of the Wheel Shuttles throughout *France*, the Province of *Languedoc* excepted, likewise a Pension of two thousand five hundred Livres Yearly, for his Life and his Son's Life after him, as likewise to be rewarded for any other Invention as it might Merit. Mr. *John Kay* has invented several Things very beneficial for Trade, which he has not yet made publick to the *French*, occasion'd by the *French* being at this Time so distress'd for Money to carry on the War, that they have stopped Payment of all Pensions and Gratuities regarding to Trade, untill Peace be made.

FINIS.

PROCEEDINGS OF THE SOCIETY.

FOURTH ORDINARY MEETING.

Wednesday, December 6th, 1911; LORD REAY, G.C.S.I., G.C.I.E., in the chair.

The following candidates were proposed for election as members of the Society:—

Child, Henry William Robert, Briardale, 33, Crediton-road, West Hampstead, N.W.

Loch, Lieutenant Percy Gordon, I.A., c/o Messrs. Cox & Co., Hornby-road, Bombay, India.

Newlands, Lord, LL.D., 36, Grosvenor-square, W., and Mauldslie Castle, Carluke, N.B.

Prankerd, Miss Edith, 51, Campden Hill-court, Kensington, W.

Hosted by Google

The following candidates were balloted for and duly elected members of the Society:—

Bates, Sir Percy Elly, Bart., Hinderton Hall, Neston, Cheshire.

Johnston, Francis Alexander, 16, Draycott-place, Chelsea, S.W.

Price, Herbert, J.P., Berry-street, Queenstown, Cape Colony, South Africa.

Roy, Charles S., Ph.D., 35, Mary-road, Stechford, Birmingham.

Singleton, Miss Esther, 854, Seventh-avenue, New York City, U.S.A.

Thomas, Cecil, 1, Great Pulteney-street, W.

Walton, Robert, 14, Rue Dieu, Paris, France.

The Chairman, in introducing the reader of the paper, said the history of no colony had probably been the object of deeper research than that of British Guiana. Composed of three provinces, all originally colonies founded by the Dutch—Essequibo, Demerara, and Berbice—it came into the definite possession of the British in 1814; an attempt to settle its boundaries was made in the forties by one of the most painstaking explorers Great Britain ever employed, Sir Robert Schomburgk, but the results of his work lay dormant for nearly half a century. The discovery of gold in 1887, and the encroachments of Brazil on the one hand and of Venezuela on the other, rendered it important that the boundary should be fixed, and Great Britain accepted arbitration early in 1896. A band of men was called together, each an expert, to collect evidence both in the colony and in the leading archives of Europe. Sir Everard im Thurn, for instance, who was present at the meeting, who had lived in the colony for many years, and who was better acquainted with the native Indians than any other white man, contributed largely from his local knowledge. The evidence dug out of archives was subjected to the learning of linguists, and in that way the vast mass of Dutch documents which came into the possession of this country with the colony was turned over to Mr. de Villiers for perusal, selection, and translation. In those documents Mr. de Villiers found not only material rich in historical interest and of legal importance, but data concerning the life of an utterly forgotten Governor who was worthy of a place in the Netherlands Valhalla, and who laid the foundations of colonies that were later to form part of the British Empire. It was the life of that man which Mr. de Villiers now proposed to place concisely before the meeting. Though the work of preparing the evidence laid before the two boundary arbitrations, that went on practically from 1896 to 1904, fell upon the band of experts he had mentioned, under the leadership of Mr. Charles Harris, of the Colonial Office, the conduct of each case fell upon the Attorney-General then in office; in the earlier of the two, that of Venezuela, the Attorney-General was Sir Richard Webster, now Lord Alverstone, and a letter had been received from his lordship expressing his regret at his inability, due to a long-standing engagement, to be present at the meeting. Lord Alverstone was the senior counsel in the British arbitration with Venezuela, and spoke for thirteen days before the Tribunal that met in Paris in 1899, and which resulted in the fixing of the boundary. Sir Everard im Thurn was also a member of the Commission, and was long resident, and a great explorer, in British Guiana; and after the paper had been read he was sure those present would be very glad to hear what he had to say on the subject.

The paper read was—

BRITISH GUIANA AND ITS FOUNDER —STORM VAN 'S GRAVESANDE.

By J. A. J. de Villiers,
Hon. Secretary of the Hakluyt Society.

The coast of Guiana was first sighted, by Spaniards, as early as 1500, though no permanent landing was effected by them until 1591, when their exploration of the Orinoco led to the establishment of the hamlet of San Thomé on that river; for more than a century, however, there was no other Spanish settlement south of it.

In the year 1596 Sir Walter Raleigh published his work entitled "The Discoverie of the Large, Rich and Bewtiful Empire of Guiana, with a relation of the great and golden city of Manoa, which the Spaniards call El Dorado."

In the year following that in which Raleigh's book was issued, and prompted most evidently by that publication, there set out for a voyage along the Guiana coast a Dutch merchant named Anton Cabeliau, who, on his return to the Netherlands in 1599, wrote so alluring an account of the wealth and trading advantages of the country—though in more sober and veracious vein than Raleigh—that a petition was almost immediately presented to the States-General for permission and aid to send colonists thither. No official sanction for this venture was forthcoming until it was embodied in the charter granted to the Dutch West India Company on its creation in 1621, but there is some evidence of private enterprise in the River Essequibo at least five years before that date. In 1625 the settlement began to be exploited by that branch of the aforesaid Company which had its seat in Middelburg, the capital of the province of Zeeland, and we can thenceforward follow its internal development by authentic and well-defined references to its trade and its officers.

In 1649 the Dutch suffered the great reverse which broke their power in Brazil. That country,

Hosted by Google

like other Dutch possessions in America, had been run by the West India Company, and by 1657, thirty-two years after its official occupation of the Essequibo River, the said body had grown weary, too, of the heavy charge of its Guiana colony, and transferred that charge to the three towns of Middelburg, Flushing, and Veere.

It is not at all strange to see these three towns —comparatively insignificant though they are to-day—embarking in 1657 upon ambitious schemes of colonisation. The middle of the seventeenth century found the United Netherlands at the very summit of their greatness—"they stood in 1648 without a rival as the first of maritime and commercial powers"—and in the three towns of Middelburg, Flushing and Veere were collected the merchants and the riches of the powerful province of Zeeland, whose Chamber represented two-ninths of the shareholders of the West India Company. That Company had been established in 1621, less with a view to steady trade and colonisation than in the hope of conquering rich lands or wresting booty from Portugal and Spain, and the determination to get rid of its comparatively unimportant Guiana colony was possibly not so much due to the loss entailed by the abandonment of Brazil in 1654 as to the attention—out of all proportion to any profits—which Essequibo required; the Company could not yet have forgotten that seven years after its own establishment Admiral Piet Heyn had with one stroke seized for it a Spanish treasure fleet (valued at one million pounds sterling) that enabled it to pay a dividend of 50 per cent.

In 1670, after an administration of only thirteen years, the three towns handed back the Guiana colony to the West India Company, but the Zeeland Chamber of that body always continued to enjoy predominant rights over the colony's trade and shipping, to the envy of the other Dutch provinces.

The beginning of the eighteenth century marks the furthest extension of the sphere of Dutch influence which had its base in Essequibo. At that date the colony was governed from Fort Kijkoveral, which stood on an island near the confluence of the Essequibo with two of its main branches; on the banks of these three streams were some plantations of the Company and others belonging to private individuals. To the eastward there was no settlement nearer than Berbice, which was formed in 1628, and the Demerara River was unopened. Westward, the sphere of the Dutch extended along the coast to the mouth of the Orinoco, and in the interior also to the neighbourhood of that river. Southward, up the main river of Essequibo, there was at that time no station, but the Company's traders were quite accustomed to journey up its tributary, the Rupununi, then to proceed across country to the savannahs which lie between Guiana and the Amazon, and probably even further to the south.

In 1704 was born Laurens Storm van 's Gravesande, the man to whom the government of the colony was entrusted from 1738 to 1772, a man so utterly forgotten even in his own country in the nineteenth century, that the late General Netscher, a Dutchman, in his "History of the Colonies of Essequibo, Demerara and Berbice"—an invaluable work to all interested in British Guiana—speaks of him as one of those meritorious Netherlanders "whose names are but little or not at all known and who nevertheless deserve to be dragged from oblivion."

Storm's life covers a very important if comparatively brief period in the colony's history. Though it cannot be claimed that there was, under his governorship, any extension of the boundaries of the vast country entrusted to his jurisdiction, yet under Storm Essequibo reached the apex of its prosperity whilst subject to Dutch rule, under him Demerara was actually commenced; by his untiring energy the desert places were peopled, by his tactical ingenuity the savage tribes were subjected, by his patriotic zeal his envious and bellicose neighbours were kept off. If not extension there was certainly consolidation.

This man, whose despatches mirror for the third of a century the history of Essequibo and Demerara, was, as we shall see, one of no mean type, and yet of a stamp common enough in the Netherlands of his time. That commonwealth, exhausted by long, ruinous and bloody wars, was, at the beginning of the eighteenth century, rapidly sinking in status as a great European power, and the men in whose veins flowed the blood of the "Beggars" would naturally lose patience in petty home politics, itching to conquer new lands and races, as their fathers had done in their country's more glorious past.

Storm van 's Gravesande came of an old family which had sat, from father to son, in the councils of Delft from the year 1270. Just a century before the birth of the future Governor, Laurens, his great-grandfather and namesake, was born in that town in 1605, but became early domiciled in Bois-le-Duc, where he filled several municipal

Hosted by Google

offices from 1640 to 1685; Dirk, Laurens' third son, born in 1646, followed his father in these and in more important posts, and out of Dirk's family of ten children, three—the father and two uncles of our hero—require mention here.

Pieter was born in 1683; he filled offices similar to those held by his father, Dirk, and died in 1721. His eldest son was Laurens, the Governor, whose life we follow to-night.

Dirk's second son was Ewout Hendrik, uncle of our hero; he succeeded to at least one of the offices held by his father, and married in 1722 a Baroness Boyd of Kilmarnock, daughter of James, captain of a Scottish company in the service of the Netherlands.

The third was Willem Jacob, another uncle of our hero; he dropped the surname of Storm, and acted in 1715 as secretary to an embassy sent by the States-General to congratulate George I. on his accession to the throne of Great Britain. His brilliancy as a mathematician gained him the friendship of many eminent Englishmen (among these being Bishop Burnet and Sir Isaac Newton), whilst the Royal Society enrolled him as one of its members. He became professor of astronomy and mathematics at Leiden University in his twenty-ninth year, and subsequently occupied the chairs of civil and military architecture and of philosophy, refusing invitations to join the Russian and Prussian Academies that came to him from Peter the Great and Frederick the Great respectively. Voltaire, who made his personal acquaintance, spoke of him as "*le profond 's Gravesande.*"

Such were the forbears and kinsmen of the man who was destined to play a prominent part in the western portion of his country's empire, in domains which, though sparsely peopled, were so rich in possibility that they attracted both the envy of the haughty Spaniard and the industry of the plodding Brit, and the influence —often a very pressing one—of these two nationalities bears largely on the Governor's life.

Born at Bois-le-Duc on October 12th, 1704, Storm van 's Gravesande entered the army in his seventeenth year, a somewhat hot-tempered youth, perhaps, for in his despatches he frequently mentions his habitual outspokenness, and late in life speaks of a quarrel he had in 1730 with his stepmother's father, the Burgomaster of Utrecht, in the following words:—

"Having always acted in keeping with the traditional Dutch outspokenness, having always, during my full seventeen years of military service, gone straightforwardly to work, and never been afraid to tell my chiefs the truth outright and, though with due respect, without circumlocution, I thereby gained their esteem, and have still by me the letter wherein my old colonel, General van Pallandt, then eighty-two years of age, did me the honour to write (upon my informing His Excellency of my intention to go to Essequibo, and thanking him for all the benefits conferred on me), that he was very pleased indeed to hear of my advancement, but that he was at the same time sorry to lose one of his best officers. His late Serene Highness, of laudable memory"—that was William IV., Prince of Orange, the Hereditary Stadtholder—"having been good enough to take the trouble to read all my letters to YY. HH., also did me the honour to say"—this must have been in 1751, when Storm was on a visit in Holland—"'You are still the old Storm van 's Gravesande—"Straightforward John"' (alluding to the affair concerning H.S.H. which I had had twenty years before with my stepmother's father, the Burgomaster of Utrecht, where H.S.H. was then studying, and which cost me my promotion), adding, 'had you stayed here you would now be one of our generals.'"

So, quitting the army, Storm elected to serve the West India Company in their colony of Essequibo, as secretary and book-keeper, and took the oath in Middelburg in October, 1737. Henceforward he was to show obedience to a body of directors who left him (sometimes for years) without the means of carrying out their instructions—to exact obedience from underfed, unwilling slaves, from selfish and disloyal colonists.

Prizing and pocketing his colonel's hearty congratulations upon his advancement, the young soldier sets out with wife and five children for his new home; and, though he doffed the soldier's coat, Storm was before all, and throughout all, a soldier. The very first subject he deals with in his first letter home is neither sugar nor shipping—the two that interested the directors most and were to give him so much trouble later—but the condition of the militia. From the men to the forts the transition was a natural one, and Storm, with that patriotic zeal and lack of mercenary motive that characterised all his actions, promptly offers to superintend the construction of a new fort, as a relaxation, perhaps, from his more sedentary secretarial duties, which, though probably irksome, were well and conscientiously discharged.

The completion of the fort in a comparatively short time, considering the difficulty experienced in procuring labour and material, gave both Storm and the colonists great satisfaction, but the militia continued to be a sore trouble to him to the very end. Without an efficient force it was impossible even to keep the slaves in awe,

let alone to repel Spanish encroachments, and year after year we find Storm urging upon the directors with wearisome reiteration the necessity of sending out reinforcements of honest, well-trained men.

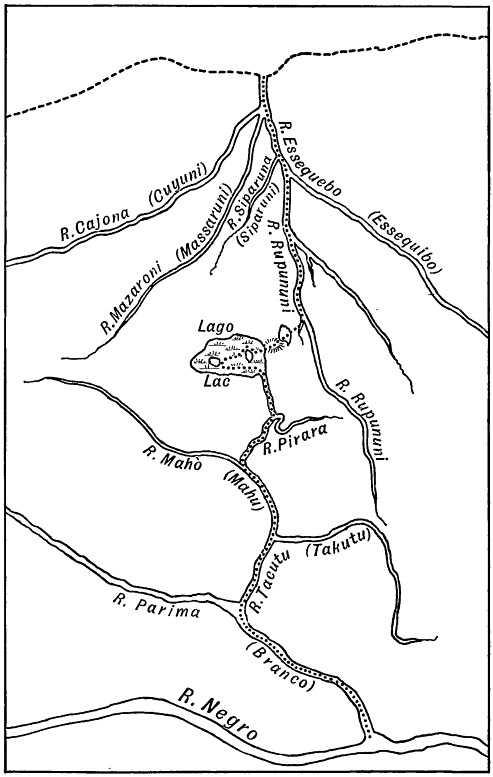
The Commander died in July, 1742, and the Councillors, appreciating the extraordinary zeal and activity displayed by the secretary, provisionally appointed him Commander whilst awaiting orders from home; the appointment was made a definite one in Zeeland on April 13th, 1743.

From that time onwards Storm's despatches teem with interest; the whole of them, covering a period of thirty-four years—from 1738 to 1772—would fill twenty-one volumes of three hundred octavo pages each. With conscientious care and in laborious detail Storm wrote from day to day on the ordinary occurrences of the colony's life. The ships that come and go from Zeeland, the cargoes that they bring, the supplies that he needs, the produce sent home, the gains by trade, the losses in certain ventures, the state of the Company's plantations, the doings of the Company's servants, of the dominie and the doctor, questions of police, matters of civil jurisdiction, the squabbles of individuals—detail upon detail that go to make up the life of a settlement—all these are found in the Governor's despatches. Basing my remarks entirely upon the contents of these despatches, which came into our possession with the colony in 1814, it is my purpose to-night to summarise broadly Storm's main policy in those matters which affected the development of the colony, and to sketch briefly, mostly in his own words, Storm the Man.

As I have already said, the territorial consolidation of Essequibo constitutes the chief feature of Storm's governorship, and in three separate ways this is disclosed in his despatches—first, in a definite policy of development and exploration; secondly, in the policy pursued towards the various Indian tribes on the coast and in the interior; thirdly, in the discussion concerning the frontiers, and Storm's stout defence of the rights of the Netherlands against Spain.

Of Storm's masterly policy of exploration I will give but one instance, though a very important one, for it finds a place in the historical geography of the world. Only a year after Storm's arrival in the colony, one Nicholas Horstman, a German surgeon in the employ of the West India Company, was sent up the Essequibo to find a passage to the Amazon River, to trade with the natives *en route*, and *en passant* to discover, if possible, Raleigh's famous but mythical city of El Dorado, situated on the equally mythical Lake Parima, a lake that was portrayed as of enormous extent on all the maps of South America till then published.

Crossing the watershed between the Essequibo and the Amazon, Horstman found the true origin of the Golden Lake, just as Robert Schomburgk rediscovered it one hundred years later. It was only a small lake—Lake Amucu—which occasionally overflowed its shores and formed a great swamp. On reaching the Rio Negro, Horstman,



Horstman's Map
from the Original in the Bibliothèque Nationale
(His route is shown thus:-..................)

either by force or by inclination (it is not clear which) remained with the Portuguese. There he met La Condamine, and handed that traveller a map of the country he had traversed, the first showing the true configuration of the land between the Essequibo and the Amazon. La Condamine handed it to d'Anville, a famous map-maker of the eighteenth century, and by him it was made the basis of a generally correct delineation of that part of the country in the first great map of South America, published in 1748. Humboldt often refers to Horstman's map

Hosted by Google

in his "Voyage aux Régions équinoxiales." It was lost for about a century, and was finally unearthed in the Bibliothèque Nationale in Paris some ten years ago, when it proved of immense value in our arbitration with Brazil, as showing the extent of the Dutch sphere of influence already at that time. And it was, of course, from the Dutch that the British inherited their claim.

Storm's policy with regard to the natives generally was a broad and enlightened one; so far as it was actuated by self-interest it certainly recognised that self-interest was bound up in the general interest of the Indian tribes. It was an advanced policy for that age. Summed up briefly, it was embodied in the following sentences from a despatch of 1769:—

"There is no one, Your Honours," says Storm, "who is more convinced how advantageous and necessary the friendship of the Indians is to this colony, because so long as we are fortunate enough to have them living around us, we are quite safe inland, and have nothing to fear concerning the desertion of our slaves"—the slaves were negroes imported from the west coast of Africa, and no South American Indian was allowed to be used as such. "I therefore neglect no possible opportunity of cultivating the friendship of the same and of protecting them from all the ill-treatment and tyranny of the whites as far as it is expedient to do, and in this way I have made myself so beloved by them, that I can now get them to do whatever I wish."

The results of the policy just described remained down to our own times. The Indians paid the British in the next century the same allegiance they had given to the Dutch, and the protection and privileges which were the natural return for such allegiance were readily accorded.

We now come to the diplomatic side of Storm's administration, and it is, perhaps, the most interesting and important of any. I have already mentioned that since their settlement on the Orinoco in 1591, the Spaniards made no progress to the south of that river for more than a century, and it was indeed a hundred and fifty years before their presence was felt within the Dutch sphere of influence.

It was in 1746 that tidings were first brought to Storm by one of the far-travelling traders that the Spaniards had built a mission and a small fort on the Cuyuni. He at once wrote home:—

"I feel not the least diffidence as to dislodging them from that place and capturing the fort, but such a step being one of great consequence, I dare not take anything upon myself, especially as the proper frontier line there is unknown to me."

There was, of course, no proper frontier line, and the West India Company merely evaded the question and left to Storm the responsibility of solving the problem and keeping off the Spaniards. Having no soldiers but a few unreliable French and Germans, the Governor had recourse to diplomacy of two kinds—playing off the Indians against the Spaniards, and inditing remonstrances that were to be laid before the States-General and referred by that body to the Court of Madrid. In 1748 Storm writes home:—

"Seeing that all my remonstrances and letters to the Spaniards are of no avail, and no redress is obtainable, I intend to tell the chiefs of the Indians when they come to me that I can provide no redress for them, and that they must take measures for their own security. Then I feel assured that in a short time no Spaniard will be visible any more in the upper Cuyuni. However, before we come to that, I will next month once more send a letter to the Spanish Governor of the Orinoco, and explain this matter to him seriously, with all courtesy, as well as the consequences, which cannot but be disastrous for them, and then await his reply, in order to govern myself thereby."

That Storm's distrust of the Spanish was very largely justified has, in late years, been proved by the discovery of documents showing that there was in 1754 a secret agreement between Spain and Portugal to make an effort, without open declaration of war, to squeeze out the Dutch from their possessions in America. Often the Governor's military ardour and patriotism would almost outrun his discretion. "If," he writes home again and again when Spanish raids had been made on undoubtedly Dutch territory, "if I were permitted to do as they are doing, I would risk my grey head once more, and make them pay doubly for the annoyance they are causing us."

But the Dutch West India Company moved with caution, and sent Storm neither encouragement for reprisal—nor soldiers. They had evidently greater faith—and in this they were for once right—in the efficacy of Storm's official despatches that I have already alluded to; these, in some measure revised and given diplomatic form, were in 1759 and again in 1769 the basis of official remonstrances to Madrid, which eventually stopped overt acts of aggression whilst Spain held the country, now Venezuela, to the north-west of the Dutch colony.

Storm's anxiety to maintain the boundaries and rights of the Dutch, and his firm stand against the aggressions of the Spaniards, were at once the foundation and the coping-stone of his efforts to consolidate the colony as a geographical unit. Just as his trading ventures and his

Hosted by Google

Indian policy fixed the geographical extension of the colony of British Guiana, so his vigorous denunciation of Spanish claims and his diplomatic measures to repel their encroachments furnish the legal basis upon which the British found their title to their one South American colony. When, 150 years after his time, the question of that colony's area came to be fought out before an international tribunal, it was Storm's work and utterances which gave such welcome support to the successors of the Dutch. Storm's governorship must, therefore, always have a living interest for the British as the period which made the present colony of British Guiana a possibility, and the history of that country can never be divorced from Storm's work.

In the early years of his administration Storm's regular despatches home were by no means so voluminous as later, but there is scarcely a letter written by the Commander that does not give the reader a closer acquaintance with the man. A soldier, his constant striving was after peace—peace within and upon his borders—and to him peace and concord were synonymous with the fear of God. The "restless spirits" that already early rendered his efforts fruitless were probably the "godless calumniators" of whom he complained so bitterly in 1745. These had evidently gained the ear of the directors in Zeeland, whose unworthy treatment of the Commander, added to their almost criminal neglect of the colony in the matter of supplies, soon rendered Storm's service bitter to him, for already in December, 1746, he applies for his discharge in most apologetic terms, the application being repeated eight months later.

How the directors replied to this is shown in a letter of Storm's dated February, 1748:—

"In the first place and before all else I find myself in duty bound to thank YY. HH. from the bottom of my heart as well for my son's promotion and the increase in my own salary as for the present of the negro with wife and child. These manifold proofs of favour, although material ones of great importance to me, and calling for deep gratitude, do not however afford me so much real satisfaction and pleasure as that which I derive from Your Honours' kind declaration that YY. HH. are pleased to approve of my services and that these proofs of favour shown me are to be regarded but as an earnest of that approval. This always having been my heart's desire and that wherein all my honour was centred imposes upon me such obligations that the power rather than the wish will fail me to fulfil them, but be assured, YY. HH., that so long as it shall please the Almighty to grant me health and strength it will be my sole endeavour and aim to further the interests of the Honble. Co. and the welfare of this Colony with all possible zeal, sparing neither trouble nor assiduity to attain that worthy object."

Though the foregoing expressions of loyalty and gratitude may appear rather fulsome, that they were not unmeaning is proved by the fact that, in spite of neglect on the part of the directors at home and in the face of tremendous difficulties, Storm held the command for a quarter of a century after. The increase in his salary was from 500 to 800 guilders, but, as he reminds the directors many years later, it was unasked for.

In March, 1749, Storm became "convinced that it would be very advantageous" to give his masters "a full verbal report" of the condition of the colony, and therefore applied for leave to visit Europe. The leave was granted, but the visit was ill-advised. Storm's absence of two years from a colony seething with godlessness and disloyalty proved too great a strain for the maintenance of what slender authority he possessed; the Commander, well received at home by the ruler, Prince William IV., and other magnates, was raised to the dignity of Director-General, and his eldest son was given the commandership of the newly-founded settlement of Demerara; the Company, however, seized the opportunity of insisting upon what is referred to as their "great reform," a system of false economy first mooted in 1744, which Storm then and frequently thereafter roundly denounced as fatal to the colony—as, indeed, it proved.

Taking what he knew to be a last farewell of all his friends in the Netherlands, since he had no interests there ever to call him back, Storm returned to Essequibo to find his authority greatly impaired, the planters regarding the head of the colony (more than ever since his visit home) as the mouthpiece of a Company which neglected their interests and sought only its own profit. Storm had henceforth a treble battle to fight—discontent within, invasion by the Spaniards ever imminent (or what was nearly as bad, a fear of it), and neglect, born of dissatisfaction, on the part of the home authorities. It was an unfortunate *cercle vicieux* —neglect at home responsible for the colony's backwardness and *vice versa.*

To Storm's official cares during this period were added domestic afflictions that weighed heavily upon him. On the last day of 1752 he lost his second son, and eight years later, within

Hosted by Google

fourteen months of each other, followed the deaths of his wife and eldest son.

The sole distraction from his troubles Storm found in the pleasure he derived from the rise of Demerara. Only a few months after his return from the Netherlands in 1752, he writes most optimistically of the progress being made by the young colony commenced under his auspices in 1746, mentioning both the activity of one Gedney Clarke, of Barbados, and the coming of other English planters from other isles.

Storm was neither Anglophile nor Anglophobe; he always spoke of the English as he found them, whilst the variance in attitude which he adopted or advocated in dealing with them was dictated not by personal caprice, or feeling, but by the varying interests of a Company whose welfare he conscientiously guarded above all else. Very soon after his appointment as Commander, he wrote home:—

"The English who have already established themselves here spare neither trouble, industry nor cost, and most of the planters are already beginning to follow their example."

General Netscher, in the work I have already mentioned, ascribes, in most emphatic language, the subsequent cession to Great Britain of the colonies of Essequibo and Demerara to this immigration of English planters, though he fully exonerates the Governor from all blame in not foreseeing this result. "When," he says, "Storm encouraged the English to settle in Essequibo and Demerara, he was undoubtedly acting wisely, for they brought with them energy and gold, both of which the colony lacked."

In the very next letter to that in which he announced Clarke's enterprise, Storm speaks of him as "a man of judgment and of large means, having the welfare of this colony really at heart." And Clarke, by his subsequent conduct, fully justified Storm's opinion of him on both these points; for, when in 1763 Demerara was threatened with a slave rising similar to that which had just ruined the neighbouring colony of Berbice, it was Clarke's activity and aid that led Storm in his letters home to admit, and more than once, that the succour sent by the English "was, after God, the salvation of Demerara."

If fault there was in allowing both planters and slaves to see the weakness of the power that ruled them, that fault lay surely not with the man who, already laden with petty administrative cares, used, in an emergency, the means nearest at hand to protect his charge, but with the Company whose almost criminal neglect drove him to such an extremity. I have shown how Storm pleaded in vain from first to last for an efficient garrison; we have extant his constantly repeated and equally vain cry for supplies. It would, however, be thought that news of a slave rising would have aroused the sleepy directors out of their lethargy. Storm advised them of the revolt in March, 1763, but at the end of September had to write:—

"The discontent is getting so great and general, that I fear for the consequences. The aid sent is so small in proportion to the immensity of the danger."

And yet, whilst Storm was compelled to lay copies of his letters home before the colonists to convince them that he at least had done his duty, the directors in Zeeland, having sent the inadequate aid just mentioned, supplemented it by a despatch wherein they "imagine the danger will have passed over before the receipt of the same." "Far is it from being so," replied Storm; "the danger is as great as, if not greater than, it ever was."

However, in the end the danger was exorcised, at what, indeed, seemed enormous cost, and Storm and the colony emerged from the crisis both a little the worse for the stress.

The shadow of the calamity which had come so near in 1763 was still upon the Governor when, in the spring of the following year, he wrote announcing the death of his son-in-law (who had been made Commander of Demerara after the death of Storm's own son, and who was his right hand in the administration):—

"My years, my poor health, sorrow, vexations, and constant opposition, in addition to the burden which is now about to fall entirely upon me, without the least help, make me weary of my office, of the country, yea, even of life itself."

The failure on the part of the Company to send out slaves or supplies was undoubtedly his chief trouble; sensitiveness to petty calumny, another; domestic afflictions a third. It is, therefore, not surprising to find the Governor once more repeating in 1766 the application for his discharge, already made with great insistence, but in vain, in 1763. The constituent bodies of the West India Company were, however, in the throes of a long dispute concerning freedom of trade with the colony, and gave little thought to relieving or releasing their old servant until a moment more opportune to themselves.

In July, 1771, Storm writes:—

"It is now eighteen months ago since we received the last goods for the slaves."

Hosted by Google

In September of the same year he says:—

"There is not a nail left to fasten anything with or to nail up the sugar casks. We are without a thing."

And again, in November, he writes:—

"Lack of provisions has never been greater. On ration day there was not an atom of meal in the stores. For myself, it does not matter; I buy what I want and pay for it out of my pocket. But the slaves, the plantations—what is to become of them?"

Worn-out and decrepit, with exhausted strength and depleted resources, Storm was to render his masters and his country one final and signal service. Early in August, 1772, a month after his release had been decided upon in Zeeland, the old Governor foreshadows trouble, hints at its cause, and explains his humane and statesmanlike efforts to stem it. But the storm burst, and once more the colony was, by a serious slave rising, brought to the brink of total ruin.

As I have said already, Storm was before all, and throughout all, a soldier. Never do we find so manly a ring in his letters home as when, in words decisive and incisive, he had to report measures taken by him in great emergencies or in the face of mortal danger. A revolt of the slaves—an ever-present menace in those days to a colony's existence—or a report of a Spanish squadron off the coast, and Storm, assuming military command quite naturally, would be marshalling his puny forces, rousing the unwarlike burghers to a sense of their duty, and meanwhile writing to the directors, all coolly but energetically, for aid—that never came.

His despatches of August and September, 1772, are all that such documents at such a time should be—exactly explicative of events and measures taken, commendatory of those who had distinguished themselves in valour, and advisory respecting future means of defence. His successor arrived in the colony in November, 1772, and Storm's career was over—*salvis honoribus*, as he had so ardently wished. He immediately retired to his plantation in Demerara, where he died August 14th, 1775, at the age of seventy-one, unknown already then to men of his own generation in his own country, which he had not visited for twenty-five years, utterly forgotten but a little later. His grandson (the only son of his eldest son) married in the Netherlands, and Storm's great grand-daughter, named Constantia Lumea, like his wife, became a Baroness van Pallandt van Beerse, allied to a descendant of Storm's old colonel, and mingling Storm's blood with that of one of Holland's most illustrious families.

The two qualities that stand out most conspicuous in Storm's nature are loyalty and incorruptibility, and better qualifications than these no Governor could have; based, too, in his case, the one upon a keen sense of honour, the other upon true piety—unshakeable foundations that were further cemented by an unmercenary spirit, untiring industry, abstemious habits, and a mode of life both strenuous and simple.

In 1746 Storm writes:—

"I live in middle-class fashion, my fare is ordinary, nay, mean, for even no wine is drunk except when there is a Church or Court meeting; I dress rather below than according to my station."

In 1762 we find him (after twenty-four years' service in the colony) inhabiting a "very small" house, "consisting only of two rooms twenty feet square and a vestibule," and a year later he says:—

"I am compelled to hold the Court meetings in the preacher's house, because there is no room in mine."

Simple and abstemious enough then as was that life the strenuousness of which has been amply proved, material reward was not the object of Storm's ambition. In 1763, after twenty-five years' work for the company, he is able to say to the directors:—

"Riches I have never hunted nor sought after, and during such long service I have never troubled Your Honours for the least increase of salary."

Mercenary indeed could not have been the man who, when daily expecting his release from office, wrote in 1771 as follows:—

"This would be an excellent year for the sales-master"—this was one of the offices he undertook in addition to the Governorship—"his dues amounting to more than 15,000 guilders, but I have good reason to fear that two-thirds of it will remain in default through non-payment and protested bills. I cannot bring myself to complete the ruin of those who, through no fault of their own, have got into deep water, and render them unable ever to get out again. I should not care to go down to the grave with their curse upon me. My children have, thank God, a crust of bread (which the Lord deign to bless), and for the rest they must do their best and trust in Him who rules all in His Omnipotence."

It is not surprising to find that the possessions of a man cherishing such sentiments were sufficiently meagre considering the length of his

Hosted by Google

career and the accumulation of his offices. In 1765 he writes:—

"It is perfectly impossible for me to exist at present upon my income, and I must get further into arrears every year; I am now already indebted for over three thousand guilders."

That there were means of amply rectifying the Company's parsimony is proved by a few simple but significant words Storm wrote home in November, 1770:—

"A certain gentleman came here to grease my palm, offering me 6,000 guilders"—that was £500, in order to get him to pass in 450 smuggled slaves —"this," he says, "I refused."

The entry upon such devious paths was, indeed, quite incompatible with a nature that held piety and pure dealing in equal honour, and honour itself "dearer than all else."

Almost every page of Storm's despatches shows how great a part religion played in his life, and of his life honour was the breath. But, as all men have the vices of their virtues, so did Storm's regard for honour lead to his one weakness—hyper-sensitiveness to opinion and hence even to calumny. "*Mens sibi conscia recti* has no need to fear calumny," he himself wrote in 1767; and, indeed, a greater disregard for the petty spite and interested cabals of the smaller men around him would have left his mind and pen more leisure to deal with larger problems and the future he was helping to shape—his body the greater repose which a tropical clime demanded; much might then have been otherwise in that administration with which he had to deal, though the tremendous odds he had to fight in the lethargy of the Company and the disloyalty of the colonists must never be forgotten.

In 1781, six years after Storm's death, war broke out between England and the Netherlands, and one of the first of our successes in the West Indies was the capture of Demerara; this was followed by the fall of Essequibo and Berbice. Between that time and the end of the eighteenth century the three colonies repeatedly changed owners, but in 1803 they once more fell to the British, whose hands they never left again, being finally ceded under the Treaty of 1814. In 1831 Berbice was united with Demerara and Essequibo; henceforth they were but three counties or provinces of British Guiana.

Immediately following that unification came the most interesting and complete series of explorations ever undertaken in the country. Robert Schomburgk was first sent out by the Royal Geographical Society as a result of a resolution taken in 1834 to explore the interior of the colony, this project having received the fullest sanction and patronage of His Majesty's Ministers. On his return to England in 1839 Schomburgk's representations as to the needs of the Indians in the south-west of the colony, and to their danger from Brazilian raiders decided the British Government that steps must be taken to stop further interference with the natives and violation of territory which was believed to belong to Great Britain. It was therefore resolved to send Schomburgk to make a complete exploration of the boundaries of British Guiana and to mark them provisionally.

Subsequent negotiations with the Venuezuelan and Brazilian Governments, however, came to a premature end without any result, and the reports of Schomburgk's surveys with the fine maps he produced lay buried for nearly half a century.

In 1886 the British Government declared the Schomburgk line to be the definitive boundary of the colony, this leading to the suspension of diplomatic relations with Venezuela in the early part of 1887, but it was not until December, 1895, when President Cleveland issued the celebrated Message, in which he called upon Great Britain to submit the whole question of the boundary to arbitration, that matters came to a head. After more than two years of preliminary argument on paper, a tribunal met in Paris in 1899, and a judgment was given which, in effect, sustained the whole claim of Britain to the Schomburgk line—a line which would have fairly satisfied the claims made by the old Governor Storm some 140 years before.

Negotiations with Brazil were actively prosecuted as soon as the award in the Venezuelan matter had been given, and these resulted in another treaty of arbitration, and in an award that may also be claimed as a considerable triumph for the line drawn by Schomburgk. Thus, by the end of 1906, only five years ago, British Guiana for the first time had its boundaries definitely fixed, and though those boundaries almost certainly did not go so far as Dutch influence at one time went, still they included most of the territory for which Storm van 's Gravesande had always contended, and to the defence of which he had devoted his life.

DISCUSSION.

Sir Everard im Thurn, K.C.M.G., in opening the discussion, said the subject of the paper was of very great interest to him, as he had spent about twenty of the best years of his life in acquiring

Hosted by Google

knowledge of the Venezuelan question. He lived in the country at the very places where Storm van 's Gravesande lived and worked, and followed the lines along which Schomburgk afterwards journeyed. Having acquired that information, he was called home to spend two years of his time in further preparation, and he then became acquainted with Mr. de Villiers, who had unburied, not in the colony, but in the archives at home, an immense mass of information which threw light upon the facts that he had been observing upon the spot. He had listened with the greatest admiration to the paper for several reasons. It seemed to him that, quite apart from the value of the author's work in regard to the settlement of the boundary, he had done a literary service in presenting a picture in such detail of a man as interesting as Storm was. He had seen a great many of Mr. de Villiers' translations of Storm's writings, and could assure the audience that, in addition to the facts which the author laid before them in his paper, Storm's despatches teemed with familiar domestic details which would serve to make a most interesting book on the subject. But, in addition to that, he thought the author's work had been most useful to all whose fate it was to study the development of the British colonial system. During the course of his life he had had a great deal to do with that subject, and had always found there were certain definite stages to be observed in the history of every colony, whether it began as a British colony or was afterwards assumed by the British. Those earlier stages were roughly three in number, the first being the unauthorised settlement of people in a place where before only natives had lived. The second stage was that in which an official, with extraordinarily inadequate means, was trying to keep in order those unauthorised settlers, who had generally been a very disorderly lot, and regulating their relations with the natives. That sort of work, which was done for so many years so strenuously by Storm was most important, but at the same time most difficult and trying, and his admiration for the way in which Storm carried out that work was unlimited. The third stage arrived when the Home Government gave the governing authority in the colony complete power, and when it established in the colony some sort of constitution and means of keeping order. That stage was carried out to a very great extent by the Dutch in Guinea before the British took it over; and the old Dutch constitution of Guiana, which this country took over in 1803, although the acquisition was not confirmed till 1814, survived with all its forms, without any change, until about thirty years ago, and was unique among British colonies. In some respects, in its retention of Roman Dutch law and Roman Dutch coinage and measures, there were points of resemblance with the Cape and the Ceylon Governments, which were originally Dutch; but in no part of the British Dominions was there so c mplete a specimen of a Dutch onstitution as that which existed in British Guiana from the beginning of the last century until about 1880. He desired to make a few remarks—not by way of criticism of anything the author had said, because he had found nothing in the paper which he could adversely criticise—but there was one small point the author mentioned about which he (the speaker) had spoken and written on previous occasions which did not seem to be realised. He referred to the curious Lake Parima, as it used to be called, or Lake Amuku, as it was known at present, which Raleigh, and so many of the old atlas makers, exaggerated to such a large extent and made to occupy nearly the whole of the interior of Guiana. The nature of that lake had not even yet been fully understood. Schomburgk's journals, which were published almost *in extenso* by the Royal Geographical Society between 1839 and 1845, had practically never been read until they were perused most diligently for the purposes of the Venezuelan Boundary Commission. Since then they had been almost forgotten again. Schomburgk's account of Lake Amuku must, he thought, have been misunderstood then, and it was no better understood now. He had many times been over the plain on which Lake Amuku was situated, and had lived in the district for six months at a time, and he found there was nothing which, except with a very great stretch of imagination, could be called a lake. In Horstman's map, which illustrated the paper, it would be seen that there were two river systems, the one going into the sea through the Essequibo, and the other beginning with the Pirara and the Mahu, running down to the Rio Negro and eventually out through the mouths of the Amazon. It would be seen that both of those systems started in a plain, in the centre of which was Lake Amuku as shown in the map. There was no such definite sheet of water as was shown there, and as was generally supposed to exist. The whole of the country between those river heads was one swampy, grassy plain in which the tiny streamlets at the head of the Pirara, and the head of various other streamlets going down through the Essequibo, rose, but at no time during ordinary dry seasons was water to be seen. If one walked through the long grass on the plain one's feet sank into the water; water splashed up round the ankles, but under ordinary circumstances there was no lake there. In heavy rainy seasons, however, the water rose, although not over any small definite area like that shown on the map, but over the whole plain. He had walked in a diagonal direction right across the plain from one side to the other, with the water never above his waist, and generally not above his knees; so that he knew from practical experience that, although a swamp existed which occasionally carried a small quantity and at other times a large quantity of water, there was no such thing as a definite lake there. The author had stated that the boundary between British Guiana and Spanish Guiana, or Venezuela, had been definitely settled, and the boundary between British Guiana and Portuguese Guiana, or Brazil, had also been settled; but, curiously enough, the whole of the

Hosted by Google

boundaries of British Guiana had not even yet been settled. There was still some considerable difference of opinion with regard to the boundary on the Upper Corcutyne between British Guiana and what was still Dutch Guiana, or Paramaribo. The question had been raised as to where the boundary existed there, but it had never been settled up to the present day, so that it was not quite accurate to say that British Guiana now enjoyed a definite boundary. That was of interest in connection with his earlier remarks that there were three stages of development in a colony, namely, the settler stage, the getting-into-order stage, and the final constitutional stage. There was another stage generally later than that, and it was only in that later stage that the boundaries of a colony were settled. In British Guiana the final definite stage had not yet been reached in which it was exactly known what territory constituted British Guiana, and what belonged to its neighbours.

The Chairman (Lord Reay), in proposing a cordial vote of thanks to the author for his extremely interesting paper, said it was difficult to understand at the present day, when people were able to read in their evening papers what the King-Emperor and the Queen-Empress had done on the same morning in Bombay, how governors in the colonies did their work when they had to wait for months until they received an answer to their despatches in the nature of instructions. To a certain extent that drawback often had its compensations. Speaking from his own experience, although a governor, on the one hand, had less responsibility when he was in constant telegraphic communication with his masters, on the other hand very often the man who was on the spot, who ought to be trusted, was hampered by considerations of a political nature at home, and by questions asked in the House of Commons which influenced, as they perhaps ought not always to influence, the policy which had to be pursued. Storm evidently was a very remarkable man, and a very good representative of those Dutchmen who had done so much to found the Dutch colonial empire. He had been very much struck with Storm's attitude towards the Indians, and the importance he attached to the cultivation of friendly relations with them. He hoped the author's paper would reach South Africa, and that the Government of that colony, taking a leaf out of the record of Storm van 's Gravesande, would follow the same principles in their relations with the Indian subjects who settled in South Africa. The problem was a very difficult and delicate one, but he thought it ought to be solved in the same way that Storm solved his. One very remarkable point was the latitude which was given both to the West India and the East India Companies in the Netherlands. It had always been a matter of surprise to him that those Companies, each of which was practically an *imperium in imperio*, were allowed such great latitude for so long a period, because it must not be forgotten that their actions could, as the paper showed, lead to international difficulties. It was quite obvious that whatever was done by Storm with regard to his relations with Spain would and might place the Government at the Hague in difficulties with Spain, and it showed the great tact which Storm displayed under most difficult circumstances that no greater difficulties were created. Another extremely important matter was the way in which Storm not only allowed, but even encouraged, English settlers in Guiana, a very wise policy which had always been followed by the Netherlands. English settlers had always been freely admitted in Java, and a great benefit had resulted from the free trade which existed in the Archipelago. In many other colonial empires preferential trade existed between the mother country and the colonies, whereas in the Dutch possessions there was absolute freedom, and a very moderate tariff, which was greatly to the advantage of the British nation. He was glad to hear from Sir Everard im Thurn's remarks that there was a chance of still another arbitration taking place, which he hoped would be as successful as its two predecessors, for settling the frontier. He had no doubt that an arbitration between the Netherlands and Britain with regard to the frontier which had not yet been settled would be of the most amiable kind, and would have the same result that all arbitrations hitherto had had between various nations, namely, to render the subsequent relations of the two countries more friendly and cordial. The immense advantage which had resulted from the Newfoundland arbitration with the United States was a case in point. In conclusion, it gave him great pleasure to move a hearty vote of thanks to the author for his admirable paper, which gave such a clear and absolutely fair view of a great Dutchman.

The resolution of thanks having been carried,

Mr. J. A. J. de Villiers, in reply, after thanking those present for the cordial manner in which they had passed the resolution, said that Sir Everard im Thurn had stated that Lake Amuku was shown on the maps to be very much larger than he found it to be. He thought the fact should be taken into consideration, however, that the map was drawn by Horstman in 1739 or 1740, and it was quite possible that the swamp had dried up considerably in the 150 years which had since elapsed. With regard to the boundary that was not yet settled, he had always heard that it was a tradition in the Foreign Office that Lord Salisbury would not allow there was any question about the matter at all; that he regarded that piece of boundary as finally settled; and that, however much the Netherlands might be disposed to open the question, this country would always resolutely set its face against it. If, however, such an arbitration was held, he would be only too happy to place his services at the disposal of the Government.

HOME INDUSTRIES.

The Case of the "Oldhamia."—The owners of the "Oldhamia" have, in the form of a pamphlet, submitted their case as against Russia to the verdict of public opinion which will sympathise with them. The lessons to be drawn from the case are of the highest importance to British industries, the facts being undisputed. Briefly, the "Oldhamia" was a Manchester ship destroyed by the Russians in the war with Japan. She was owned by the Manchester and Salford Steamship Company, Ltd., and was in 1905 carrying a cargo of petroleum owned by the American Standard Oil Company. Near the island of Formosa she was captured by the Russian cruiser "Oleg," searched, and eventually sent on to Vladivostock with a prize crew on board. They navigated her so carelessly that she ran on a sandbank, and the officer in charge, without attempting to get her off, set fire to her and destroyed her. She burned for a month, and the Russian officer stood by for the whole time watching her burn. The loss was estimated at over £60,000, and the owners claimed compensation from the Russian Government. At the instance of Lord Lansdowne the owners brought their claims before the Russian Prize Court at Libau. "If after legal remedies have been exhausted a denial or miscarriage of justice is apparent," wrote his lordship, "the propriety of diplomatic intervention will be considered." The Russian Prize Courts refused compensation, and diplomatic assistance was again requested from the British Foreign Office. Sir Edward Grey, on December 19th, 1909, said that it would be given, and on January 4th, 1910, he instructed the British Ambassador at St. Petersburg to inform the Russian Government of the "entire dissent" of the British Government from the findings of the Prize Courts, and on August 27th, 1910, the owners were informed by Sir Edward Grey that he had urged the Russian Government, in default of compensation, to consent to the case being submitted to arbitration by the International Tribunal at the Hague. The Russian Government refused, and on November 8th last the owners received a letter from Sir Edward Grey in which he informed them of this refusal and added that "no useful purpose would, in the opinion of the Secretary of State, be served by attempting to reopen the case." It is not necessary to go into its merits, though it may be said that in the opinion of the best authorities in this country it cannot be reasonably contended that the lighting petroleum carried by the "Oldhamia" was capable of being used as fuel, and therefore liable to capture as "conditional contraband," and even if the contrary could be shown the condemnation was illegal, because the particular cargo was consigned to a private person, and no evidence was offered to show that it was destined for public use. Moreover, the burning of the ship was an act of piracy, and the captor was bound to make compensation without respect to the question whether the capture was valid or not, since there was no pretence that the failure to destroy would involve danger to the safety of the warship, or to the success of the operations in which she was engaged at the time. The lesson to be drawn from the "Oldhamia" case is that such cases ought not to be decided, so far as judicial proceedings are concerned, by the court of one of the interested parties alone. As matters stand, the question as to the legality of the capture, and the propriety of the captor's action, is tried solely in the courts of the belligerent captor. The neutral has no appeal beyond the courts of the country against whose agent he is bringing his action. "Diplomatic action" is of no use. An ultimatum is the next step, and an ultimatum would probably mean war, and to declare war because the Russian Supreme Court gives a judgment which we consider unjust would obviously be out of the question. The case of the "Oldhamia" demonstrates very forcibly the importance to neutral shipping of securing a trial on appeal to a court composed in the majority of neutrals, and it was this consideration that led the British Government to support the scheme for the establishment of an International Prize Court at the Hague. If the Declaration of London is ratified, cases of capture of neutral ships will be sent on appeal to such a court, where the neutral involved will be represented.

Railway Fares.—It was recently mentioned in these Notes as probable that, in order to meet their increased wages bills, the railway companies might find it necessary to increase passenger fares, and it is now stated that they are preparing for an increase. The financial position of most of the lines will not permit of proposed concessions to the employees unless they can be made good by an increased revenue, and it is said to be the present intention to increase fares at varying rates from 5 to 12½ per cent., and to confine the increase, at any rate at first, to special traffic like week-end tickets and excursions.

Shipbuilding on the Thames.—It is still thought possible in some quarters that the Government may reconsider their decision and give an order for another battleship to be built on the Thames. The difficulty in the way is that work cannot be executed as cheaply on the Thames as elsewhere. There was the same trouble forty years ago, when Samuda Bros. had a yard in the river. For a time they did well, but prices fell and the Admiralty offered Mr. Samuda a contract to build a battleship at a price which would leave a loss. He was not prepared to take the loss, but he called his men together and explained the position. If they were to be paid at the current rate of wages, somewhere about 7*s.* a day, there would be a loss of several thousand pounds; if they would accept 1*s.* a day less the accounts would balance and the firm would take the order. If the men doubted the figures they might call in an independent accountant to verify them, but the men, under union rules, declined, as they would no doubt decline to-day if a similar offer was made to them.

Hosted by Google

The Cotton-holding Scheme.—According to Messrs. Neill Brothers, "a leading New York firm is reported to be endeavouring to form a syndicate for the purpose of assisting the South to hold the remainder of its cotton for higher prices. The method is to be for planters to make over their cotton to the syndicate, receiving an immediate advance of £5 per bale, and 75 per cent. of any profit shown when the cotton is ultimately sold. In return the planter is now to promise to reduce his acreage next season by 25 per cent. It strikes us that this is an absurd suggestion. Planters as a class are now fairly well to do, and able to hold a fair proportion of their own cotton if they wish; and if they need assistance there is plenty of loose capital in the South ready to advance much more than £5 per bale on cotton now presumably worth £9 to £10. Why, then, should the planter deprive himself of the use for next year of one quarter of the land which now yields him, say, £9 per bale in order to obtain an advance, which he does not require, of £5 per bale? May not the effect of this New York effort rather be to suggest to the shrewd planter that he had better hurry up and take the £9 or £10 per bale which he can now obtain by selling his cotton, rather than give it into the hands of people who value it so low as a security as £5 per bale or 2½*d.* per lb.? The proposal, however, if seriously meant, only shows to us what fears must be felt of the excessively large crop unduly depressing the prices of cotton when such artificial methods are resorted to in order to raise them."

Threading Weaver's Shuttles.—Mr. J. Hester and Mr. W. H. Horrocks, of Prestwitch, have applied for protection of a new way of threading weaver's shuttles. The invention is a shuttle in which the hole is large enough for the thread to be pushed through with the finger. The shuttle is drilled through crossways near the tip and a piece of brass tubing is inserted. This has a hole cut in it at the top. To thread this shuttle the weaver makes his knot of thread with his first two fingers, pushes it through the top hole with his forefinger, and then out of the tube at the side with his little finger. It is claimed that the movement is as easy and as quick as sucking, and sucking is impossible with this form of shuttle. The thing may be used as either a right or left hand shuttle. It is said that existing shuttles can be readily converted, and that a number are already in use in various sheds.

CORRESPONDENCE.

AEROPLANE EFFICIENCY.

In the discussion on aeroplanes reported in your issue of December 1st, it is stated that the Aircraft Factory chart, for which I not unnaturally took credit, was anticipated in 1903 in France. From a mere recollection of resemblance, Mr. A. R. Low asserts that there was, *therefore*, anticipation. I propose to state what the Aircraft Factory chart showed about an aeroplane, and to invite proof of the prior claim.

It showed body resistance and wing resistance at all angles and speeds, it showed the best climbing speed and how to select it, the best speed for minimum petrol consumption, the best speed for gliding, *i.e.*, the best gliding angle, the available margin of horse-power at each speed, the total range of speed of the aeroplane in question. It was not a theoretical case, but was verified by trials on the design at Farnborough. It was not a single case, but was plotted for three aeroplanes reconstructed at the Aircraft Factory, and for three well-known foreign makes.

It is now for Mr. Low to prove what he says.

MERVYN O'GORMAN,
Supt. of H.M. Aircraft Factory.

GENERAL NOTES.

THE SILK ASSOCIATION OF GREAT BRITAIN AND IRELAND AND THE INSURANCE BILL.—This Association has issued a statement as to the effect the National Insurance Bill, if passed in anything like its present shape, may be expected to have upon the silk industry. The competition of France, Germany, Italy, and even the United States, is very keen, and the position of the silk trade is such that "even a small burden upon the industry becomes a serious factor in the keen competition with foreign manufacturers which now exists." The complaint of the silk manufacturers is that the Bill does not recognise the fundamental difference which exists between the conditions of male and female labour, and that silk manufacturers who employ a large proportion of females as compared with males are especially penalised by any disadvantages under which the employer of female labour will suffer under the Bill. Out of one hundred boys who commence learning a trade, the majority become more or less efficient workmen, but of every hundred female learners only a small proportion, estimated in various trades at from 20 to 50 per cent., remains available to the employer. This operates upon the employer of females very inequitably under the Bill, as the increased proportion of female learners compared with male learners means an increased proportion of those earning a learner's wage. Under the proposed Bill the employer has to pay 3*d.* weekly for all employees between sixteen and twenty-one years of age. Thus the weekly payment by the employer for a girl learner earning 5*s.* weekly is the same (3*d.*) as the weekly payment by the employer of male workers earning, say, 30*s.* weekly. From actual returns made by twenty-three of the chief silk factories of the United Kingdom, it is found that the employers' contribution for female employees will cost 2·838 per

Hosted by Google

cent. on their wage bill, whereas the cost to employers of male labour amounts, in most cases, to less than 1 per cent. In some sections of the silk industry, the cost to the employer for his female workers amounts to 5 per cent. on the wage bill. Nor can it be said that the employer of female labour is making a larger proportionate profit than the employer of male labour. The amount paid in wages under competitive conditions to various classes of labour is approximately in proportion to the earning power to the employer of the labour in question. The Association contends that, bearing in mind the facts that one female out of every two ceases work after a few years to become married, that the period when such females are at work is the healthiest period of their lives, and that every such person creates what may be termed a lapsed policy, no justification is to be found in the Bill, or in the report of the actuaries, for the proposed total of *6d.* jointly contributable by the employer and the employee.

MEETINGS OF THE SOCIETY.

Ordinary Meeting.

Wednesday evening, at 8 o'clock:—

December 13.—W. Yorath Lewis, M.Am. Soc.M.E., A.M.I.Mech.E., A.M.I.E.E., "Continuous Service in Passenger Transportation."

Indian Section.

Thursday afternoon, at 4.30 o'clock:—

December 14.—J. Travis Jenkins, Ph.D., D.Sc., Superintendent of the Lancashire and Western Sea Fisheries, "Fisheries of Bengal." Sir Steuart Colvin Bayley, G.C.S.I., C.I.E., will preside.

Cantor Lectures.

Monday evenings, at 8 o'clock:—

Professor Vivian B. Lewes, "The Carbonisation of Coal." Four Lectures.

Syllabus.

Lecture III. — December 11. — *The Thermal Conditions existing during the Carbonisation of Coal.*—The heat of formation of coal—The work of Euchene, Mahler, and others—The cause of the endothermic nature of some coals—The thermal value of the reactions taking place in the retort—The losses of heat in a retort setting—The transmission of heat through the retort and charge—The effect of temperature and travel on the primary products of decomposition — The temperatures existing in retorts and ovens—Small charges and full charges—The influences which lead to improvement in the products from full charges, chamber and vertical retorts.

Lecture IV. — December 18. — *The Possible Improvements in Carbonisation.*—The aims of the gas manager and coke producer—Experiments on low temperature distillation and their teaching—The rivalry existing between fully-charged retorts, vertical retorts, recovery ovens, and chamber carbonisation — The intermittent vertical retort *versus* the continuous vertical systems—The Settle-Padfield, Duckham-Woodall, and Glover-West processes—The ideals of carbonisation—The volume of gas due to primary and secondary reactions—The gasification of tar—The limitations of volume and quality of gas—The ends to keep in view in devising new processes of carbonisation.

Papers to be read after Christmas:—

Cecil Thomas, "Gem Engraving."

F. Martin Duncan, "The Work of the Marine Biological Association."

H. A. Roberts, M.A., "The Relations of Science to Commerce and Industry."

John Nisbet, D.Oec., late Conservator of Forests, Burma, "The World's Decreasing Timber Supplies."

Frank Warner, "Silk."

Charles C. Allom, "The Development of Artistic Skill in the Applied Arts."

Cyril Davenport, "Illuminated MSS."

Ernest Kilburn Scott, Assoc.M.Inst.C.E., M.I.E.E., "The Manufacture of Nitrates from the Atmosphere."

Charles Bright, F.R.S.E., M.Inst.C.E., M.I.E.E., "The Administration of Imperial Telegraphs."

Harold Cox, "The Interdependence of Morals and Economics."

Professor G. W. Osborn Howe, "Recent Progress in Radio-Telegraphy."

E. D. Morel, "British Rule in Nigeria."

Gordon Craig, "Art of the Theatre." Miss Ellen Terry will preside.

Theodore E. Salvesen, "The Whaling Industry of To-day."

Leonard Hill, M.B., F.R.S., and Martin Flack, M.A., M.B., B.Ch., "The Influence of Ozone in Ventilation."

Professor Ernest A. Gardner, M.A., "Greek Sculpture."

George Fletcher, "Technical Education in Ireland."

Colonel Sir Thomas H. Holdich, K.C.M.G., K.C.I.E., C.B., D.Sc., "The North-East Frontier of India."

The Rev. Walter K. Firminger, B.D., Senior Chaplain, Bengal Establishment, "The Old District Records of Bengal."

E. A. Gait, I.C.S., C.I.E., Census Commissioner for India, "The Indian Census of 1911."

Walter Saise, D.Sc., M.Inst.C.E., F.G.S., "The Coal Industry and Collier Population of Bengal."

Hosted by Google

NEVILLE PRIESTLEY, Managing Director, South Indian Railway, "Indian Railways."

W. A. LEGG, M.Inst.C.E., "Irrigation in South Africa."

ALAN BURGOYNE, M.P., "Colonial Vine Culture."

JUVENILE LECTURES.

Wednesday afternoons, at 5 o'clock:—

CHARLES VERNON BOYS, F.R.S., "Soap Bubbles." Two Lectures.

Syllabus.

LECTURE I.—JANUARY 3.—The surface actions of water and other liquids—Peculiar properties of solutions of soap and of saponine with which bubbles may be blown—The strength of bubbles—Soap films on frames—Froth—Composite bubbles.

LECTURE II.—JANUARY 10.—Out-of-door bubbles—Floating bubbles—Soap bubbles as an aid to experiment—Experiments with soap bubbles—The colours of soap bubbles—Permanent celluloid films showing the colours of soap bubbles.

The Lectures will be illustrated by numerous experiments.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, DECEMBER 11...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Professor Vivian B. Lewes, "The Carbonisation of Coal. Lecture III.—The Thermal Conditions existing during the Carbonisation of Coal."

Sanitary Engineers, Institute of, Caxton Hall, Westminster, S.W., 8 p.m. Mr. James Farley, "The Standardisation of Vitrified Ware Pipes."

Brewing, Institute of (London Section), Criterion Restaurant, Piccadilly, W., 8 p.m. Mr. G. R. Seton, "Appliances used in the Retailing of Beer, and their Proper Use."

Economics, London School of, Clare Market, W.C., 5 p.m. Dr. M. Phillips, "State Insurance."

Surveyors, 12, Great George-street, S.W., 5 p.m. Mr. W. A. Haviland, "The Burden of Upkeep on Rural Estates and its Relief under Section 69 of the Finance Act, 1910."

Post Office Electrical Engineers, Institution of, at the Institution of Electrical Engineers, Victoria-embankment, W.C., 6 p.m. Mr. E. A. Pink, "Distribution by Means of Parallel Cables."

Victoria Institute, 1, Adelphi-terrace House, W.C., 4.30 p.m. Dr. Ludwig von Gerdtell, "Natural Law and Miracle."

London Institution, Finsbury-circus, E.C., 5 p.m. Miss R. Travers, "Finland."

Architectural Association, 18, Tufton-street, S.W., 7.30 p.m. Mr. A. E. Munby, "Is the Texture of Materials a Fetish?"

Alpine Club, 23, Savile-row, W., 8.30 p.m.

TUESDAY, DECEMBER 12...Sociological, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8.15 p.m. Miss Mabel Atkinson, "Domestic Life and the Consumption of Wealth."

Asiatic, 22, Albemarle-street, W., 4 p.m. Mr. V. A. Smith, "Indian Painting from the XVI. to the XVIII. Century."

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Dr. T. E. Stanton and Mr. J. R. Pannell, "Experiments on the Strength and Fatigue Properties of Welded Joints in Iron and Steel."

Pharmaceutical, 17, Bloomsbury-square, W.C., 8 p.m. 1. Professor H. G. Greenish, "Caraway Cultivation in Holland." 2. Mr. G. Claridge Druce, "A Visit to Japan."

WEDNESDAY, DECEMBER 13...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. W. Yorath Lewis, "Continuous Service in Passenger Transportation."

Biblical Archæology, 37, Great Russell-street, W.C., 4.30 p.m.

Automobile Engineers, 13, Queen Anne's-gate, S.W., 8 p.m. Mr. L. H. Pomeroy, "Engine Design for Taking Advantage of Horse-Power Rating Rules."

United Service Institution, Whitehall, S.W., 3 p.m. Captain Sir T. A. A. Cuninghame, "Mechanical Transport in the Field."

Japan Society, 20, Hanover-square, W., 8.30 p.m. Dr. A. Westarp, "Japan ahead in Music."

Royal Society of Literature, 20, Hanover-square, W., 5.15 p.m. Professor Henry Newbolt, "Poetry."

Engineers, Junior Institution of, at the Institution of Electrical Engineers, Victoria-embankment, W.C., 8 p.m. Major H. B. Strange, "Steel Specifications considered Commercially."

China Society, Caxton Hall, Westminster, S.W., 8.30 p.m. Rev. J. Macgowan, "The Drama in China."

THURSDAY, DECEMBER 14...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Indian Section.) Dr. J. Travis Jenkins, "The Fisheries of Bengal."

Cyclists' Touring Club (Metropolitan District Association), at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. F. H. Small, "Through Normandy and Brittany on a Cycle."

Royal, Burlington House, W., 4.30 p.m.

Concrete Institute, 296, Vauxhall Bridge-road, S.W., 8 p.m. Mr. G. C. Workman, "Some Recent Works in Reinforced Concrete."

Early English Text Society, in the Theatre, King's College, Strand, W.C., 5.30 p.m. Mr. H. B. Wheatley, "Dr. Furnivall and the Work of the Early English Text Society."

London Institution, Finsbury-circus, E.C., 6 p.m. Mr. Emile Lesage, "A Frenchman's View of England."

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Rev. T. T. Norgate, "Joan of Arc."

Electrical Engineers, Victoria-embankment, W.C., 8 p.m. Mr. A. E. Seabrook, "Residence Tariffs."

Mathematical, 22, Albemarle-street, W., 5.30 p.m.

FRIDAY, DECEMBER 15...British Academy, in the Theatre, Burlington-gardens, W., 5 p.m. Professor R. A. Stewart Macalister, "The Philistines, their History and Civilisation."

Engineers and Shipbuilders, North-East Coast Institution of, Bolbec Hall, Newcastle-on-Tyne, 7.30 p.m.

Mechanical Engineers, Storey's-gate, Westminster, S.W., 8 p.m. 1. Discussion upon paper by Mr. J. Hartley Wicksteed, "Double-Cutting and High-Speed Planing Machines." 2. Mr. R. Godfrey Aston, "Oil-Burning Locomotives on the Tehuantepec National Railway, Mexico."

Civil Engineers, 25, Great George-street, S.W., 8 p.m. (Students' Meeting.) Mr. E. F. Hunt, "Tests on Reinforced Concrete."

SATURDAY, DECEMBER 16...Engineers and Shipbuilders, North-East Coast Institution of, Newcastle-on-Tyne, 7.30 p.m. (Graduates' Section.) Mr. C. Ian Burrell, "Design and Construction of Aeroplanes."

Hosted by Google

Journal of the Royal Society of Arts.

No. 3,082. VOL. LX.

FRIDAY, DECEMBER 15, 1911.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, DECEMBER 18th, 8 p.m. (Cantor Lecture.) Professor VIVIAN B. LEWES, "The Carbonisation of Coal." (Lecture IV.)

CANTOR LECTURES.

On Monday evening, December 11th, Professor VIVIAN B. LEWES delivered the third lecture of his course on "The Carbonisation of Coal."

The lectures will be published in the *Journal* during the Christmas recess.

INDIAN SECTION.

Thursday afternoon, December 13th; Sir STEUART COLVIN BAYLEY, G.C.S.I., C.I.E., in the chair. A paper on "The Fisheries of Bengal," was read by Mr. J. TRAVIS JENKINS, Ph.D., D.Sc.

The paper and discussion will be published in a subsequent number of the *Journal.*

JUVENILE LECTURES.

The usual short course of lectures adapted for a juvenile audience will be delivered on Wednesday afternoons, January 3rd and 10th, at 5 o'clock, by CHARLES VERNON BOYS, F.R.S., on "Soap Bubbles."

Each Member is entitled to a ticket admitting two children and an adult.

A sufficient number of tickets to fill the room will be issued to Members in the order in which applications are received.

Members who require tickets for the course are requested to apply for them at once.

LIST OF MEMBERS.

The new edition of the List of Members of the Society is now ready, and can be obtained by Members on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

FIFTH ORDINARY MEETING.

Wednesday, December 13th, 1911; CAPTAIN G. S. CAMPBELL SWINTON in the chair.

The following candidates were proposed for election as members of the Society:—

Burns-Begg, Colonel Robert, The Residency, Salisbury, South Rhodesia, South Africa.

Cochrane, His Honour Judge Andrew January, Maysville, Kentucky, U.S.A.

Hart, William Edward, M.A., J.P., Kilderry, Londonderry, Ireland.

Heming, Arthur, 8, James-street North, Hamilton, Ontario, Canada.

McKerrow, George, M.D., 7, Barns-street, Ayr, Scotland.

Morgan, G. S. Delmar, B.A., Kuala Lumpur, Selangor, Federated Malay States, and Thatched House Club, St. James's-street, S.W.

Tubby, Alfred H., M.B., M.S., F.R.C.S., 68, Harley-street, W.

Veitch, Henry Newton, 22, Old Burlington-street, W.

The following candidates were balloted for and duly elected members of the Society:—

Costello, John Francis, B.A., Camp, Sholapur, Deccan, India.

de Villamil, Lieut.-Colonel Richard, Carlisle Lodge, Rickmansworth.

Foord, Charlton Willoughby Hougham, 23, Kitson-road, Barnes, S.W.

Harrop, Edwin, 109–119, Rosebery-avenue, E.C.

Heath, Dudley, Pembroke Lodge, Winchmore-hill, N.

Huntsman, Henry William Tite, Rions, Northwick Park-road, Harrow, Middlesex.

Morgan, George, I.S.O., Downings, Wallington, Surrey.

Stout, Arthur Purdy, 574, Madison-avenue, New York City, U.S.A.

Hosted by Google

The paper read was—

CONTINUOUS SERVICE PASSENGER TRANSPORTATION IN RELATION TO THE LONDON TRAFFIC PROBLEM.

By Wm. Yorath Lewis, M.Am.Soc.M.E., A.M.I.Mech.E., A.M.I.E.E.

At the recent Portsmouth meeting of the British Association, the author delivered a paper on "Continuous versus Intermittent Service in Passenger Transportation,"* and therein briefly indicated on the one hand that the characteristic of all systems of transport in general use—viz., "Intermittency"—is the root cause of their inherent limitations; their excessive initial and operating costs; and their inability to meet satisfactorily the requirements of the dense traffic usual in all great cities: on the other hand, that, by resorting to the continuous plan, the traffic could be handled in streams instead of in crowds with remarkable advantages in every respect. He further partially disclosed a new continuous system devised to perform services which cannot be met by the electric train, or any other system, whether "intermittent" or "continuous." In the meantime he has written a series of articles on "The London Traffic Problem"* in the *Daily Chronicle*, reviewing the situation, and indicating that the key to the solution of that problem may possibly be found in the "Adkins-Lewis System of Rapid Continuous Transit." Let us now consider the matter further.

* Copies of these are available in pamphlet form, and should be read in conjunction with this paper.

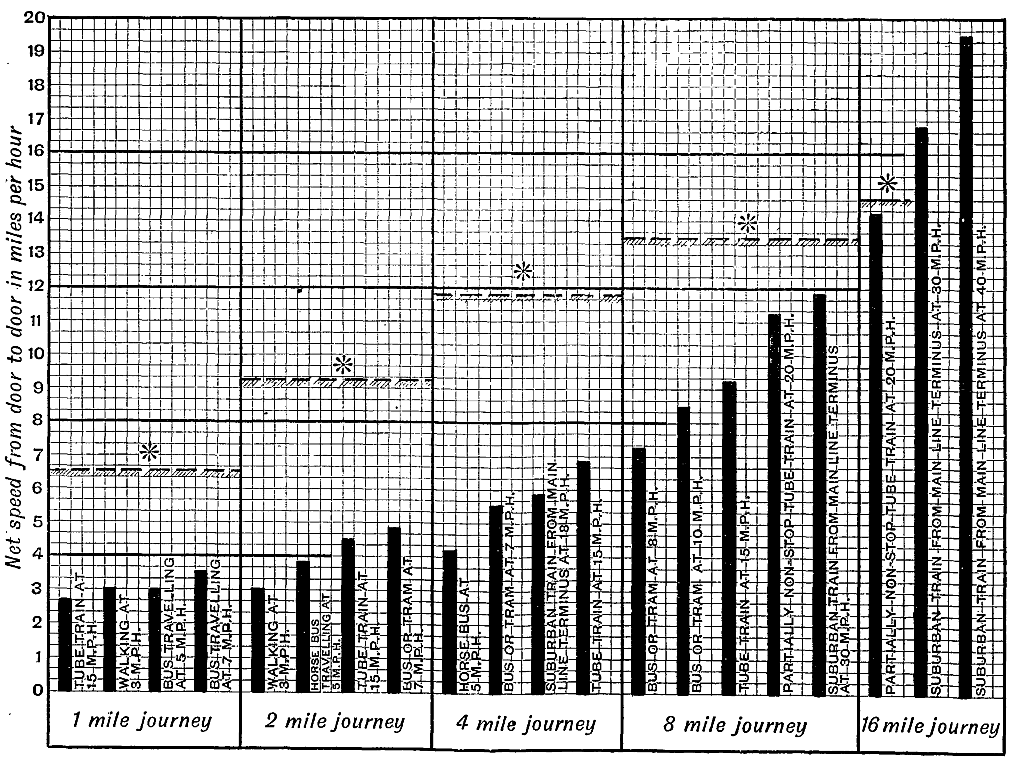

Fig. 1.—Effective "Door-to-Door" Speeds.

In this diagram it is assumed, for journeys *viâ* buses and trams, that four minutes are occupied at each end in walking and waiting before boarding and after alighting.

When the journey is *viâ* tube railways, six minutes are assumed to be occupied in walking to and from the nearest station, and six minutes in getting between street and train, and *vice versa* (owing to lifts, passages, etc.).

When for comparatively long distances the journey is *viâ* suburban or main line terminals, twelve and a half minutes are allowed at each end on the assumption that traveller has considerably further to walk.

* The effective door-to-door speeds that would be given by the Adkins-Lewis shallow subways, with four stations per mile, are shown by dotted line.

Hosted by Google

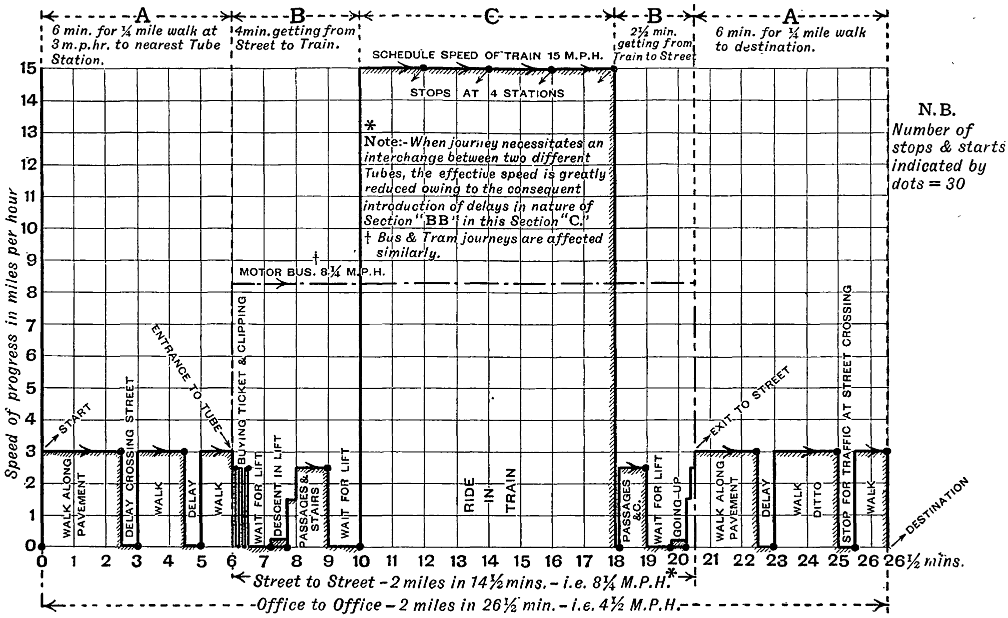

FIG. 2.—AVERAGE TWO-MILE JOURNEY "DOOR-TO-DOOR" SPEED, *viâ* TUBE RAILWAYS AND MOTOR BUSES.

NOTE that, in order to give schedule speed of 15 miles per hour on route having two stations per mile, the train has to attain a maximum or "crest" speed of about 25 miles per hour.

Referring then to the situation, but only very briefly, What is it? Nobody really knows! And, what is more, nobody can possibly find out. Even the Government have not the power to obtain the data necessary for a proper study of the problem in its entirety—in all its aspects. What everybody knows, however, is that there is a great deal of congestion and confusion in all directions. It is generally known also that ordinary passenger fares average six-tenths of a penny per mile.* Perhaps it is not so widely known that the effective speeds are ridiculously low—much lower than they are in New York, for instance. Let us see what the millions which have been sunk in tubes, trams, and buses provide Londoners in point of speed.

Fig. 1 gives the effective "door-to-door" speed attainable between destinations at various distances apart, when the journey is made by the different means. The effective speeds are so wretchedly low that there results a heavy and extravagant taxicab traffic. The demand for a cheaper mode of transit than taxis, and a more convenient and effective one than is furnished by the sub-surface facilities, especially for short journeys, results in a very dense motor-bus traffic. The density of street traffic is completed by an exceptionally heavy commercial and mail traffic, because practically all of this is street-borne. Of course, the resulting street congestion lowers the effective speed both of passengers and freight. Consequently all the individuals in the community, and especially traders and business men, suffer acutely. The net result is a colossal waste of time—an embargo on trade. Now London must see to it that the extent of this embargo on her prosperity is not greater than it is in other cities on their prosperity. In fact, London must do more. She must not only have the best and cheapest transit facilities, but must make for the greatest all-round efficiency.

But why is it that the effective speed about the central area is so inferior, when there is such a network of tubes having an intense service of 25 to 30 miles per hour trains, giving schedule speeds of 15 to 16 miles per hour? Let us examine Fig. 2. In the first place, owing to its characteristic—"Intermittency"—the electric train system is limited to not less than about half-mile distances between stations for the schedule speed of 15 or 16 miles per hour. Thus it is that the average journey to or from the nearest tube station is at least a quarter of a mile or a five or six minutes' walk (including street crossing delays) at three miles per hour. In the second place, the tube trains are run at intervals of from one and a half to three minutes, involving an inevitable wait. In the third place, the tubes

* See Table 2, Appendix F. iv. p. 137, Board of Trade London Traffic Branch Report, 1911.

Hosted by Google

are situate at deep level, necessitating lifts operated intermittently, also involving delay. There are other items detrimental to efficiency, but, now referring to the diagram, we see that a journey from a City office to another one two miles distant involves so many delays that the effective speed overall (" door to door ") is only $4\frac{1}{2}$ miles per hour, whilst the " street-to-street " speed *viâ* the tube is only $8\frac{1}{4}$ miles per hour. Shorter journeys, of course, are worse.* The one often has to wait for accommodation; and the same is equally true of trams.

Now look at Fig. 3. This gives the effective "street-to-street" speed for tube railway journeys of various lengths, when the schedule speed of the train is 16 miles per hour, which is above the average in London on routes having two stations per mile. The effect of a six minutes' total time loss in getting between street and train, and *vice versa*, which is a fair average over

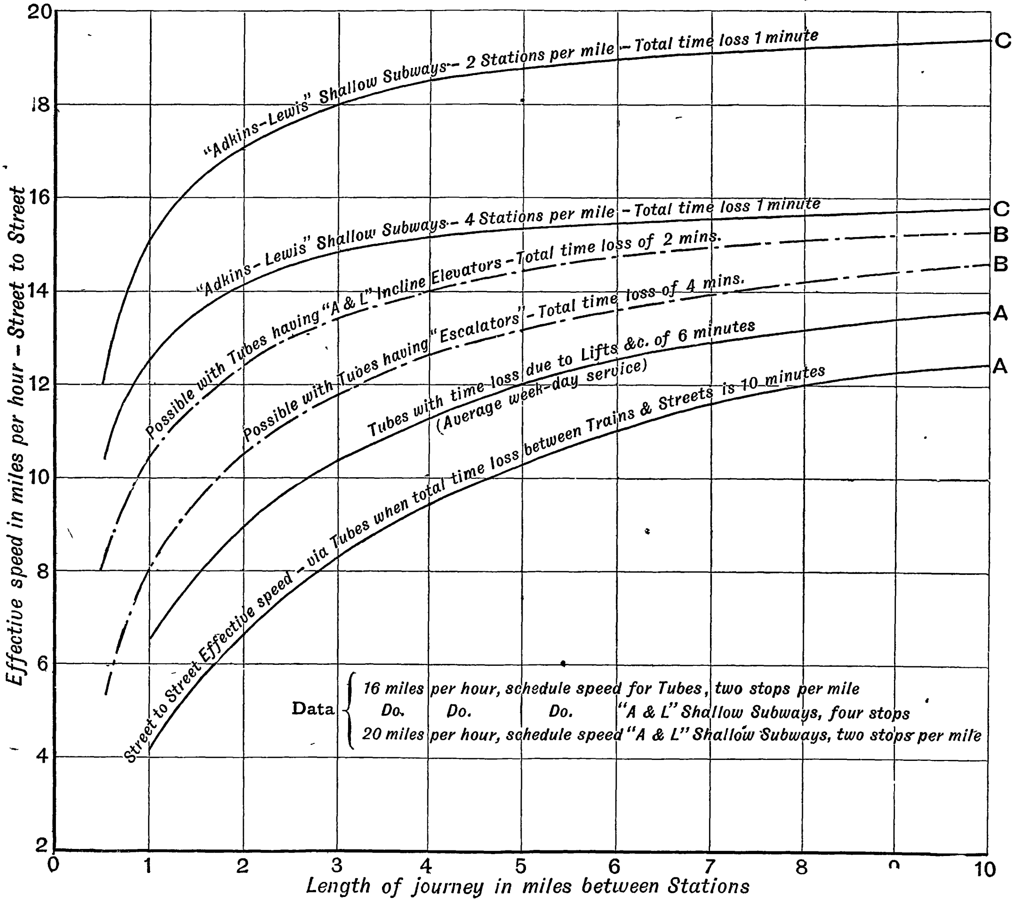

FIG. 3.—EFFECTIVE " STREET-TO-STREET " SPEEDS.

Curves AA—Tubes with present lifts.
,, BB—Tubes with continuous elevators.
,, CC—Adkins-Lewis subways.

diagram also shows the result of negotiating the same journey *viâ* motor-bus, and it will be noted that the effective speed is about the same, though certainly less distractive. Buses also are run on intermittent service, and, owing to overcrowding, all the stations, and all times of the day, is to reduce the effective "street-to-street" speed for a one-mile journey to $6\frac{2}{5}$ miles per hour; for a two-mile journey to slightly under 9 miles per hour; and for a three-mile journey to $10\frac{2}{5}$ miles per hour; even for a six-mile journey to only $12\frac{3}{5}$ miles per hour. Remembering that the vast majority of journeys taken is in the neighbourhood of two miles, and that it takes, say, six

* For journeys of one mile from "door to door" the effective speed averages only about $2\frac{3}{4}$ miles per hour, whether by tube or bus. Thus, by walking one can often go quicker and always save a penny.

Hosted by Google

minutes to walk a quarter of a mile to and from the nearest tube station each way, the average Londoner gets about town at the rate of $4\frac{1}{2}$ miles per hour, if he uses the tubes. The effective service on the District and Metropolitan is somewhat better because they are shallow subways. Let us now similarly consider the effective "street-to-street" speeds *viâ* trams and buses. Their schedule speeds* are about 8 miles per hour in the central area. If we take two minutes as the average delay due to waiting, filling up, etc., the effect is to reduce the "street-to-street" speed on a one-mile journey to $6\frac{3}{10}$ miles per hour; a two-mile journey to $7\frac{1}{10}$ miles per hour, and a three-mile journey to $7\frac{3}{10}$ miles per hour. Allowing three minutes walking time at each end of a journey to and from the nearest tramway or bus station, we find the overall effective "door-to-door" speed for a two-mile journey to be $5\frac{1}{5}$ miles per hour. Thus, for the majority of Londoners taking short journeys about town, the surface facilities are about 15 per cent. superior to tubes in point of speed, and considerably better in point of mental wear and tear.

In the case of longer journeys, however, the tubes have the advantage, though not always, for if a journey involves an interchange between two tube systems, the buses often provide a superior service. Much may be said in condemnation of the comfortless and noisy travelling afforded by all the existing facilities, but there is some hope for improvement in this direction, especially as regards the bus services. There will, however, always be considerable annoyance and discomfort associated with all intermittent services.

In regard to fare rates, there is not much prospect of any material reduction from the prevailing rates,† which give the railways and tramways a very meagre profit. Still there are possibilities in this direction in the motor-buses, though the general public are not likely to reap any benefit. On the contrary, the continued growth and increased speed of motor-bus traffic, at least in the central area, can only be viewed with alarm, since the streets are already sufficiently dangerous and "delayous" to pedestrians. The casualty list*—about 367 fatal and 13,856 serious non-fatal accidents in the streets of London every year—is a bigger calamity than most earthquakes, but as it is so distributed it passes unnoticed. The future, however, *must* be viewed with alarm, if the only relief for the present congestion is to be secured by increasing the speed of vehicular traffic. This, it is supposed, will result when motors completely supplant horses. Fig. 3, however, shows how the tubes could greatly improve their effective speeds by adopting continuous elevators.

Let us now examine the inherent nature of city, urban, and suburban traffic. It is practically that of a continuous flowing stream, varying considerably in volume, at more or less definite periods of each business day—maximum density occurring at morning and evening, during what is known as the "rush hours."†

Usually the flow is along well-defined and regular channels, but periodically the traffic stream is diverted, and is often greatly augmented in volume according to special circumstances, which, however, unlike the weather, can generally be predicted with more or less certainty. The means for dealing with this human stream should consequently partake, so far as practicable, of a *continuous* as distinguished from an *intermittent* nature.

Passenger traffic is always demanding improved facilities, and every improvement is readily appreciated. Each new development is undoubtedly of benefit to the community, as also, generally speaking, to the whole of the previously existing systems, because of the growth of the travelling habit which is thereby encouraged. All existing facilities are being more and more severely taxed, by reason of the steady growth of the population, and expansion outwards towards the suburbs, with resulting increase, not only of the number of journeys per head of population, but also of the average length of journeys. Those engaged in the operation of transportation systems are endeavouring to meet the demand by intensifying their service. They are trying more and more to approach the condition of a

* See Sir Herbert Jekyll's 1911 Report. Table 18, Appendix F. iv. p. 154, gives average motor-bus speeds in central area taken in May, 1909, as 7·1 miles per hour. It may be taken that the speeds have somewhat increased since then, though in November, 1911, the schedule speed of motor-buses for the two-mile journey (twopenny fare) between Piccadilly Circus and Queen Victoria Street in seventeen minutes is still 7·1 miles per hour.

† See Table on pp. 120–121.

* See Sir Herbert Jekyll's 1911 Report, giving on page 76 the records for 1910. Compared with 1909, the fatal accidents increased 21 per cent., and non-fatal accidents about 6 per cent.

† This objectionable characteristic could be minimised by the provision of improved and cheaper facilities, encouraging ladies and other residents of the suburbs to come to the West End oftener. The effect of a late morning and early afternoon "rush hour" of shoppers and sightseers would be beneficial to all, and would considerably increase the mid-day traffic in the central area.

Hosted by Google

continuous service, but they are severely baulked by the intermittent character of their systems, in some of which the commercially attainable limit has been reached.

Considering the serious inherent difficulties to be contended against, they are to be highly congratulated upon the remarkable results attained. Mr. Stanley and his able staff on the District Railway, in particular, deserve great credit and praise for their splendid work. Forty, and still more fifty, six-car trains per hour run on the District Railway, even though only over a short section, and during the rush hours this is a magnificent achievement.

Let us investigate this—*i.e.*, the absolute limit of the train system for a single track in each direction—a service far greater than can be attained in the New York subway, and beyond the capabilities of any of the London tubes. Without going into the details of operation to indicate the extravagancies involved in securing such a capacity, we may note that the capacity of 50 six fifty-seat-car trains per hour is 15,000 seats per hour. The duration of stops at stations for this service cannot appreciably exceed ten seconds, thus the time available for stepping in and out of the trains is only eight minutes twenty seconds per hour at each station. Obviously, therefore, the railway is available for only about 14 per cent. of the time, and but a comparatively small capacity can be handled from each station. Naturally this difficulty has to be overcome by filling the trains at a terminal, or at stations having island platforms—as suggested by Arnold, but of course such provisions considerably add to capital cost.

This is only one of the detrimental features of a periodic service. Now, the result of damming a human stream flowing at the rate of three miles per hour, if the volume is four abreast and six feet apart, and if the period of check is only one minute, consists in the accumulation of 176 people—meaning discomfort, and a serious time loss of more than one minute, because of the time required to enable this detachment to board the conveyance, pending the arrival of which it had accumulated. Obviously, if, instead of interrupting this human stream, accommodation could be provided with a capacity of about three seats per second passing through a station, at sufficiently slow speed to enable passengers to step on or off the cars, all the delay and congestion would be eliminated. There would neither be the need of a station platform nor of trains, long and large enough to accommodate the congestion. The facility would be available for 100 per cent. of the time, provided the seating capacity had not been already occupied at previous stations.

Now let us see what has been done to meet the requirements on these lines. So far only one system has been put forward and brought to a successful issue. That is the Multiple Speed Moving Platform. The author is indebted to Mr. Max E. Schmidt, President of the Continuous Transit Securities Co., of New York, for the following information regarding this arrangement.

The moving platform idea was proposed in 1872, but the first equipment was not operated until twenty-one years later, and then in a crude way at the Chicago Exhibition of 1893. Since then it has been worked in Berlin, and an extensive route of about three miles, built on improved lines, was installed in the Paris Exhibition of 1900. In the meantime the designs have been greatly improved and remodelled for city service. The slide shows an elevation, from which it will be seen that the system comprises three or more adjacent platforms, caused to move at three, six, and nine miles per hour respectively, by frictional contact of the tracks which they carry, and which rest on pulleys of diameter proportioned to give the desired relative speeds, mounted on a cross shaft and driven by electric motors. Supporting shafts are spaced 3 ft. 9 ins. apart, and driving shafts with motors are located every 202 ft. 6 ins. along route. The power consumption is remarkably low *—about 150 horse-power has been found sufficient to keep 900 tons of loaded platform running at six miles per hour. This system possesses extraordinary advantages over the train system, particularly in point of capacity, effective speed and low operating cost. It has proved beyond question the feasibility of continuous transit in public service by carrying without accident at least twelve million public passengers (each having had to make several speed changes) of all classes and nationalities. This is supported by the Public Service Authorities of New York State, who have approved and authorised its adoption. In fact, it may be safely stated that the list of those engineers and experts prominent in handling the practical end of the transportation problem, who have endorsed and approved the system, comprises as strong an aggregation of talent as has ever studied a similar problem.

The slides exhibited show in plan and in elevation a big installation contemplated in New

* See Hobart's "Electric Trains," p. 24.

Hosted by Google.

York. One slide represents the equipment pictorially. It will be seen that four platforms are proposed, the maximum speed platform being run at twelve miles per hour, and having seating accommodation thereon—a capacity of 73,500 seats per hour can be secured—*i.e.*, three times the seating capacity of the New York four-track subway when run at maximum service, with which it also compares favourably in point of effective speed. That eminent authority on the transit problem, Mr. Bion J. Arnold, recognising the limitations of the train system, and the advantages of the continuous plan, has in his recent reports directed serious attention to the moving platform proposition.

It may be here asked, Why is it that the moving platform has not yet come into general public service? The advantages of continuous conveyors and processes have long been recognised in the industrial world. Indeed, continuous lifts have been in passenger service in London for thirty years, and the moving stairway and other continuous devices have been at work for quite ten years. Why is it, then, that the continuous method has not been applied in the sphere of rapid transit?

The author feels sure that it is not because the negotiation of platforms or vehicles "walking" at the rate of three miles per hour is not feasible for public service. He believes that if Sprague had not introduced the multiple unit system of train operation about the same time that the moving platform was installed and run so successfully in Paris in 1900, the continuous system would have been by now commonplace. As it was, however, the "locoless" train became the fashion—and, by the way, there is too much "fashion" in engineering work. Still, the moving platform scheme, though extremely simple, and advantageous in many ways, is obviously too cumbersome and costly, especially in respect of the space and constructional accommodation it requires. In some respects it is even too capacious. Then, again, it necessitates eight negotiations of three miles per hour speed change for passengers to get up to and down from a maximum speed of only twelve miles per hour. It really is but a rather awkward attempt to get over the limiting feature of all other existing continuous systems—viz., the uniform and necessarily low speed, which alone has barred their progress. They do not fully meet the requirements of the ideal long sought and recognised to be a system which is:—

(1) *Continuous* in motion, so that the journey may be commenced immediately upon arrival at the starting place, to avoid crowding, consequent discomfort and delay.

(2) *Speedy* in action, so that distances may be traversed in the shortest possible time. Consequently, as of necessity the speed must be relatively slow at stations, so that passengers can readily mount and dismount, it must be capable of acceleration and deceleration between a minimum speed at stations and a maximum speed *en route*.

Furthermore, these requirements must be met with due regard to and adequate provision for:—

(*a*) Convenience, comfort and safety to passengers.

(*b*) Reliability, simplicity, and compactness with accessibility.

(*c*) Low initial cost in equipment and constructional accommodation.

(*d*) Low operating cost in power, attendance, maintenance and general charges.

Hosted by Google

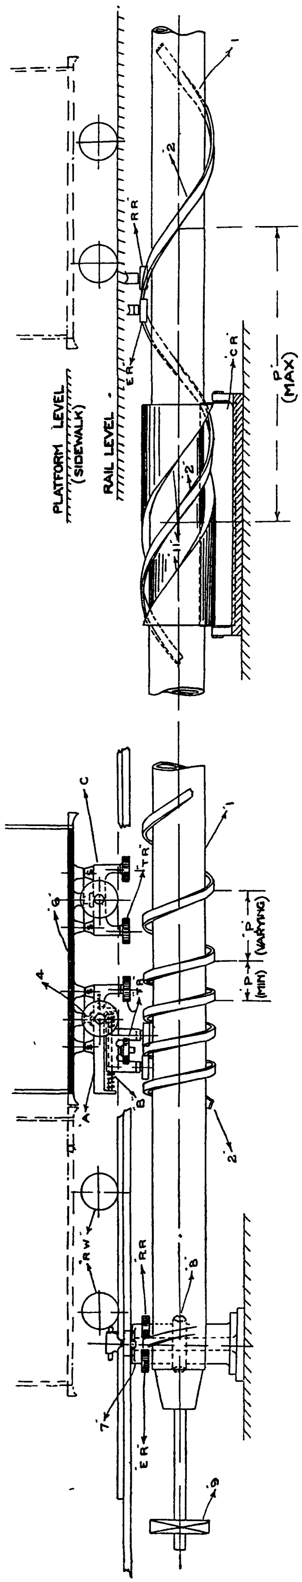

FIG. 4B.—DIAGRAMMATIC SIDE ELEVATION OF ADKINS-LEWIS SYSTEM.

NOTE.—Cars in close proximity to each other when engaged at minimum pitch portions of driving shafts (left-hand illustration).

Measured by this standard, neither the moving platform nor any other existing device can be claimed to comply with the requirements for their respective duties. The author will, however, now deal with the Adkins-Lewis system, which he submits as capable of fully meeting the essentials (1) and (2), and with handsome and amply adequate regard to the conditions enumerated (*a*), (*b*), (*c*), (*d*). It should be here mentioned that this system is capable of numerous applications, such as vertical and inclined elevators and combinations thereof for both passengers and freight—also to transporters for mails, parcels and almost any class of goods and materials either on the fully continuous, semi-continuous, or even the intermittent plan. The application which will now be considered is that for city passenger service over routes of any length, profile and curvature, in more or less shallow subways.

Referring to Fig. 4, diagrammatically representing the arrangement, it will be seen that the driving means employed comprise a spiral threaded shaft, "L," which is rotated at constant speed. Engaging with the spiral thread "2," are rollers "ER" and "RR" mounted with spring connection "B" to the under side of the leading truck, "A." The running wheels are flangeless and roll along the tracks "S." The leading and trailing trucks are designated respectively "A" and "C." Upon these trucks is mounted the car-body "6," through the medium of springs "S." The trucks are also provided with guide-rollers "TR," rigidly fixed thereto, and located centrally between the running tracks "5." These guide-rollers "TR" run in a chase forming side-tracks "3," to resist the side-thrust occasioned by the angularity of the spiral-thread drive, and to guide the trucks (which swivel under the car-body "6" about the pins "4") *en route* and around the ends "Z." Here the reverser "7," driven by the worm and wheel "S," suitably connected with the driving shafts by means of gearing "9," meshes with the projecting shank of the leading guide-roller "TR" before the engaging roller reaches the last thread convolution of the shaft by which it has been driven. The reverser "7" thus takes the car around the ends and serves to put the "ER" into correct engagement with the first convolution of the thread upon the other shaft for the return journey. The driving shafts are carried at suitable intervals upon cradle rollers "CR," forming bearings of the well-known "anti-friction" type. At the places where these cradle-rollers are located, a

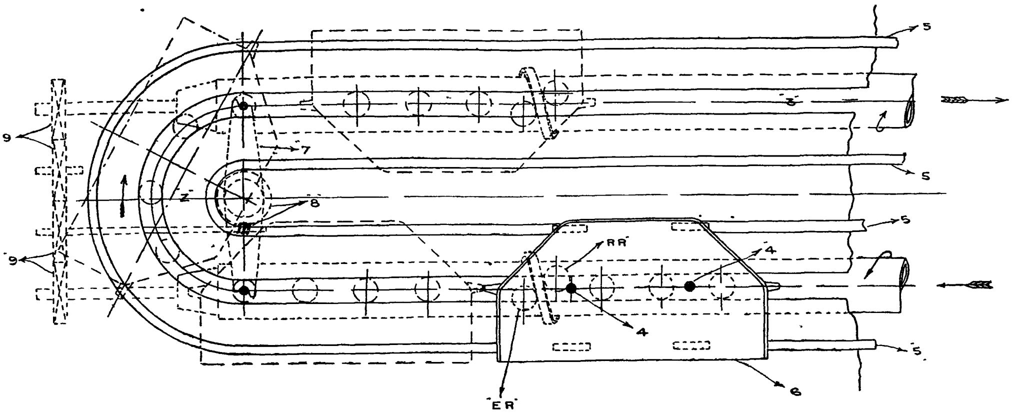

FIG. 4C.—DIAGRAMMATIC PLAN OF ADKINS-LEWIS SYSTEM.

NOTE.—The end of the route is shown, to illustrate how the cars are taken out of engagement with the last thread on the one shaft and put into correct engagement with the first thread of other shaft by means of the reverser, which also propels the cars around the short radius end curve.

muff or boss "10" is mounted. This muff or boss is slightly larger than the outside diameter of the screw thread, and is provided with a spiral groove "11" on either side of the thread "2," so as to permit the passage of the engaging and retarding rollers "ER" and "RR." The length of the muff or boss "10," and of the cradle-rollers "CR," is proportioned to be sufficient to ensure an adequate bearing.

As the driving shafts are rotated at constant speed, it follows that the speed imparted to the cars engaging therewith will be proportional to the pitch of the thread. For traversing stations the pitch and thread angle is low (approximately 8°), and provides a uniform slow speed. But, in order to provide a high speed *en route* between stations, the pitch and angularity is steep—namely, 45° (or even as much as 53°). The change from low to high pitch, and *vice versa*, to provide acceleration and deceleration, is *gradually* increased or decreased, as the case may be. Herein lies the outstanding feature of the system, and this is further dealt with in connection with efficiency, return of energy to line, and acceleration, later on in this paper, but more particularly in the author's British Association paper.

The cars are always engaged on an equal number of threads apart, irrespective of the pitch; the number of minimum pitch-threads being so selected as practically to equal the overall length of one car. The obvious result of this is that peculiar advantages are secured, viz., that the cars congregate in close formation at the stations, and that they space out to considerable distance apart when at high speed *en route* between the stations, so that, compared with any system of uniform speed platform, it is clear that very

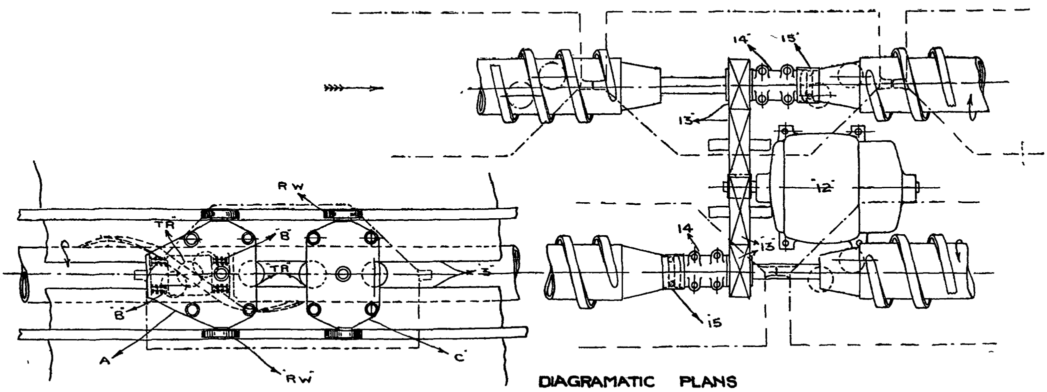

FIG. 4D.—DIAGRAMMATIC PLAN OF ADKINS-LEWIS SYSTEM.

NOTE that where cars are in close proximity to each other, as at stations, a gap is made in the spirals, which permits of the insertion of driving motors, thrust bearings, etc.

much less rolling-stock is required by this system. The close formation of the cars at the stations permits convenient means for introducing adequate provision for applying the motive power to the driving shaft, and also taking care of the end-thrust* due to the reaction of the cars, propelled by the spirally-threaded driving shafts. Referring to Fig. 4, it will be seen that if the overall length of the cars is made practically equal to the number of minimum pitches between adjacent engagements, the cars will just touch each other. Obviously, then, a gap in the spiral can be made at the close-pitch section, and this gap provides for the reception of the driving motor "12" and the bearing "14," with which is incorporated the thrust-ring "15." Clearly, the cars will be pushed over the gap by those following, thus ensuring correct engagement with the recommencing thread on the other side thereof.

The motive power is applied to the driving shafts on both routes simultaneously by the introduction of gearing "13" cross-connecting them, and taking the motor drive at the centre between tracks as shown. Similarly, as will be shown later, curves and changes of grade can be negotiated by introducing bevel gears which enable any length of driving shaft to be set at any angle with the adjacent length. In this case, also, advantage is taken of the gap in the thread to insert bearings and thrusts. Since the cars are absolutely controlled and regulated automatically by the engaging rollers "ER" and "RR" respectively, operating on the leading and trailing sides of the thread "2," and coming into action respectively at periods of acceleration and deceleration, there is no necessity of any braking and signalling system, such as are all-essential with the train system. Furthermore, there is no necessity to employ drivers and train conductors, nor for the numerous skilled and unskilled attendants connected with the train system at sub-stations and power-house.

Reference to Fig. 5, which represents for the purpose of comparison the layout of electrical equipment and power supply for the two respective systems, clearly indicates that most of the costly adjuncts inseparable from electric traction are entirely dispensed with in the "Adkins-Lewis" system. The provision of electricity for driving the shafting may, as

* The end-thrust is not of serious amount, since the reaction due to accelerating cars is largely counterbalanced by decelerating cars.

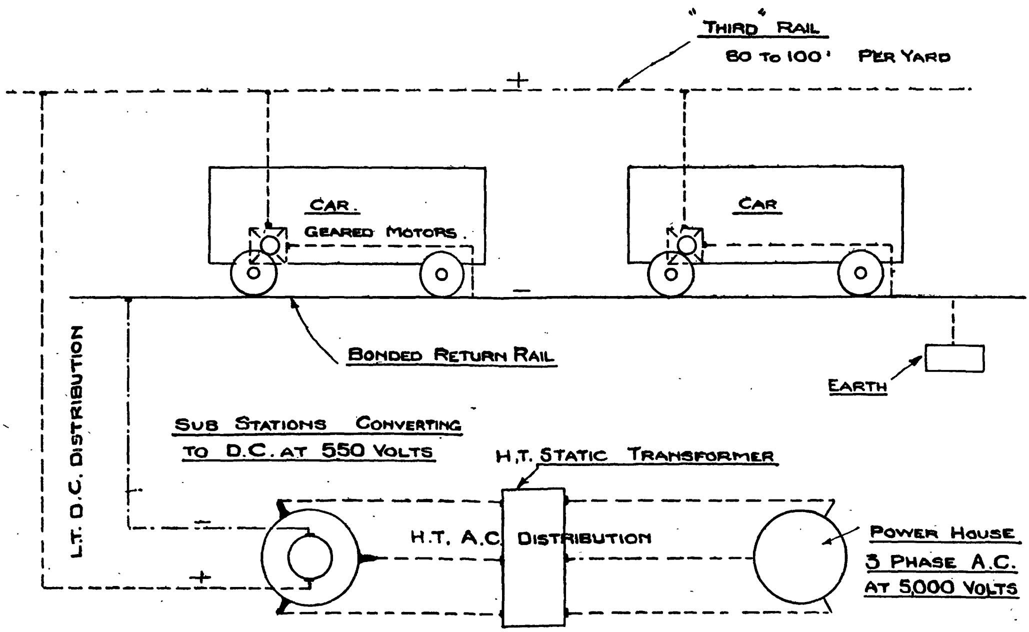

FIG. 5A.—DIAGRAM OF ELECTRIC TRAIN SYSTEMS. EQUIPMENT AND LAY-OUT OF POWER, PLANT, AND DISTRIBUTING ARRANGEMENT.

N.B.—The overall efficiency—power-house to car-wheels—is 51% *only*, and the energy consumption per seat-mile is 50 to 60 watt-hours for 16 miles per hour schedule speed, on route having two stations per mile.

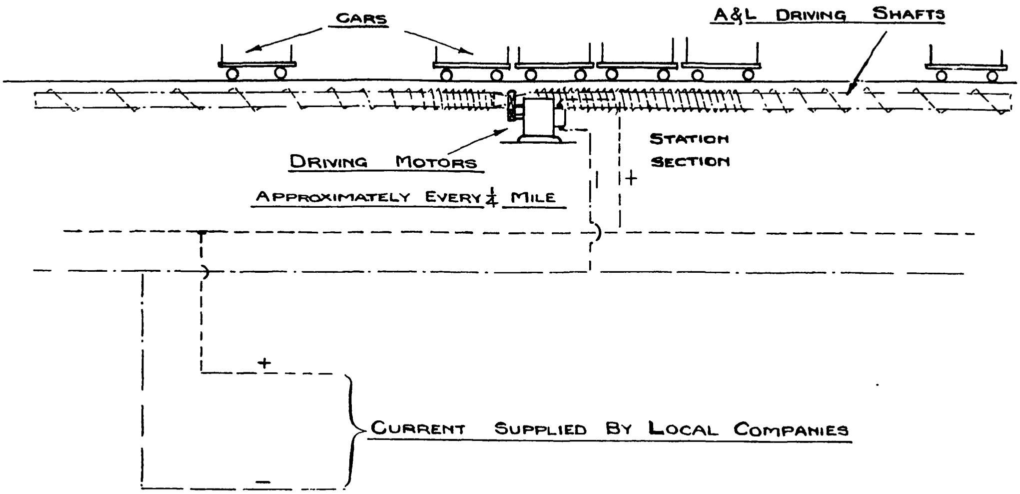

FIG. 5B.—DIAGRAM OF ADKINS-LEWIS SYSTEM—EQUIPMENT AND POWER SUPPLY.
Compare with Fig. 5A.

N.B.—The overall efficiency—power-house to car-wheels—is 70%, and the energy consumption per seat-mile is only 12 to 15 watt-hours for 16 miles per hour schedule speed, and *four* stations per mile.
The cars do not carry any driving motors and complicated control apparatus.
The spiral shafting is driven by electric motors located at quarter-mile intervals.

indicated, be entrusted to the local electricity supply companies through whose areas the route passes. The particular kind of current as regards pressure, or as regards whether it is continuous electricity or alternating electricity, is immaterial, as different kinds may be employed on different sections of the route. Thus the introduction of this system would enable those concerned in electricity supply undertakings to partake of a very acceptable load, the amount of which, though not large, would be practically constant for about eighteen hours of the day.

In order to give an idea of what the system would look like in actuality, a perspective sketch of the equipment in a tube is shown on the screen. Observe that the two tracks pass through one tube, that the cars pass back to back; and that in the station they are in close formation like a train. They are, however, whilst *en route*, widely separated from each other. Obviously, this is advantageous, and due to the original spacing of the cars an equal number of spirals apart, irrespective of the pitch, and to making the length of the cars equal to that number of times the minimum pitch—if they are required to touch each other—or slightly less in length, if they are not ever required to touch. When a car completes its progress at very slow speed through a station, it begins very gradually to increase its speed, and continues to accelerate to maximum speed with such perfect graduation that the speed change will be absolutely imperceptible to passengers.

Likewise with the deceleration on approach to the next station. The perfection of graduation attainable permits of high rates of speed change being employed. During these periods doors or gates, of the safety non-pinching type, will automatically close and open, remaining open whilst cars pass through stations and closed whilst *en route*. The station will always be full of cars, because when one is leaving, another is arriving at the other end. Notice that the track is invisible, as the cars are so close together, also that there is no room to get between them, and there is no train before which one could fall in front, even if some poor dejected passenger contemplated suicide. The side walks shown alongside the tracks between the stations are not for passengers' use, except in case of a complete stoppage, when, and only then, they would be available for exit to nearest station along the subway, which, as indicated, would be well lighted and white-tiled throughout.

The length of the station needs to be only 50 ft., or at most 75 ft. A car moving at three miles per hour would take seventeen seconds to pass through. Thus there would be eight seconds for passengers to step out of the cars during the passage of the first half of the station, and nine seconds for other passengers to step in during the passage through the other half of the platform. As a matter of fact, it does not require a

Hosted by Google

second of time for even a slow-moving person to step over a line. Now it will be noticed that the car floor is flush with the platform level. Also that practically the whole side of the car is open for ingress and egress.

Here let us recall the District Railway's aggregate of 500 seconds' stop per hour at each station, and 15,000 seats per hour maximum capacity, remembering that there are eighteen doors available on each six-car train. If, then, 4,500 passengers wanted to step in and out of the trains per hour at each station they would have to "step lively" at the rate of one door per second. Moreover, both "in" and "out" going passengers would have to use the same doors and sections of platform at the same time. It could not be done. Even the spacious platforms could not accommodate the congestion. Of course it is more than is usually demanded.

But now let us see how such a traffic flow would be handled on the Adkins-Lewis system. There would be two streams, one going on through one half-length of the station and the other coming off using the other half-length of station. Each being of 4,500 passengers per hour would mean streams of seventy-five passengers per minute. If the walking speed be the usual three miles per hour, we should have each stream a single file of passengers each over a yard apart, or two abreast $2\frac{1}{3}$ yards apart. The "oncoming" stream would always be under check at the turnstile entrances to the station at street level, and would be controlled by the collector, who would regulate the flow according to the capacity available. The "off-coming" stream would have amply spacious exits and platform space. Now the carrying capacity of the equipment shown in the picture is 9,900 seats per hour, passing any point, plus 60 per cent. standing room, which may here be neglected. Thus, if there were 4,500 passengers riding through per hour, and 4,500 getting both on and off at each station per hour, there would still be 900 empty seats per hour passing through each station, or 5,400 seats available for the 4,500 passengers getting on. Designating the broad double opening in the side of each car as one "entrance," there would be available for each of the 4,500 "on-coming" passengers four entrance-seconds or one entrance for four seconds. Each passenger would have a choice of four cars extending for about twelve yards along platform. Similarly each "off-going" passenger would have one double exit for four seconds. Thus, even this heavy flow, which we found could not be negotiated by the District Railway, even with 50 per cent. more capacious service, could be handled quite conveniently by the "A & L" system. Of course it is far greater than would be usual in the case of a route having four stations per mile. For the conditions when the traffic-flow would be either all "on-coming" or "off-coming," the entire length of the station could be utilised, and at terminal stations, of course, the length and width of the stations would be suitably proportioned.

The point that the author wishes to emphasise is that by handling the passengers in *streams* instead of in *congregations* much greater capacity and comfort can be secured, and that accompanying these advantages are others even more important.

One of them is—owing to compactness, freedom from vibration, etc.—the accommodation need not be in the nature of deep tubes. Slide F shows pictorially the Adkins-Lewis equipment installed in a shallow subway. Thus access and egress between street pavements and the cars would be within a few seconds—say twenty or at most thirty seconds—including the time for paying the fare and passing through the turnstiles.* Now let us refer back to Fig. 3, which shows that with a total time loss of one minute, and a schedule speed of sixteen miles per hour, which the system provides when there are four stops per mile, the effective "street-to-street" speed for a one-mile journey would be $12\frac{1}{2}$ miles per hour, a two-mile journey $14\frac{1}{10}$ miles per hour, a three-mile trip $14\frac{3}{4}$ miles per hour—obviously, from 100 per cent. to 50 per cent. superior to those provided by tube railways for equivalent journeys (see Fig. 3). The average "getting about speed" would be still better, because there would be twice as many stations per mile consequently the walking time between any destination and the nearest sub-surface station would be only a matter of $2\frac{1}{2}$ minutes, instead of six minutes' walk on the average. The dotted lines in Fig. 1 give "door-to-door" speeds for various length journeys, *viâ* Adkins-Lewis shallow subways.

Referring to the author's articles on the traffic problem in the *Daily Chronicle*, wherein he stated that about thirty miles of such equipment would practically solve the problem, the wall map indicates the routes proposed. They need not now be discussed, though their effect would be

* By adopting turnstiles and uniform fare of one penny, the present ticket nuisance could be eliminated.

Hosted by Google

very far-reaching.* The question is, "Does the Adkins-Lewis system render such facilities practical and possible, and if so are they desirable?" The author suggests that the Royal Commission's proposed "Traffic Authority" alone could determine the answer to the latter question, and, as to the former, he submits that not only is the continuous plan feasible for public service, but also that the Adkins-Lewis system is both mechanically and commercially sound, considered as means to attainments which cannot be reached in any other visible way. Let us consider the matter broadly.

One of the first points to consider is the possibility of tearing up the streets to construct in London, as in New York and elsewhere, shallow subways. Notwithstanding that the Royal Commission indicated affirmation, this may not be possible, but luckily such a procedure is unnecessary. The Adkins-Lewis system attains the ideal set up by that body—viz., "Stations *only* at or near the surface and the rest down low." All that it requires is a few basements under the pavements every quarter of a mile on alternate sides of the street. The rest, being at low level, could clear the obstructions, and by zigzagging diagonally across and along the streets, even easements for going under basement property can be largely avoided. This is because grades and curves can be very easily negotiated in the Adkins-Lewis system. Still the author would like to take this opportunity of urging the desirability of the Government conceding the Royal Commission's recommendation regarding procedure. It is in the interest of the community that way-leaves be granted under Royal Parks *free*, and under property upon payment for *structural damages only*. These privileges hold good already in the case of main sewers. Why not in the case of sub-surface railways? The resulting benefits would be relatively much greater.

Now consider some practical designs. First, the application to comparatively short transporters for interconnections and inclines up to about one in fifteen. The slide gives the general arrangement of such a transporter, which was prepared for, and, had there been sufficient time last spring, would have been installed at the Crystal Palace to carry passengers between the Low Level Station and the Palace Terrace. It is interesting to note that both Scotland Yard and the local authority, amongst others, approved the plans and sanctioned the equipment. The capacity of this is 4,500 standing passengers in each direction per hour, when the initial speed is only 1½ miles per hour. It should be here explained that the capacity is always proportional to the initial speed, and with a fixed ratio, the maximum and average speed is likewise governed by the speed of the driving shaft, which, of course, can be regulated by an electric motor over a very wide range. From the cross-section shown in the figure, it will be seen that the entire equipment of both tracks, including side walks, can be accommodated in a 10 ft. diameter tube. Thus ample capacity and speeds averaging about ten miles per hour can be compactly provided by the application of the system to feeders, and interconnections for existing underground railways, surface tramways, and similar services. For these purposes the equipment is very economical, both as regards initial and operating cost.

A representative design for a "tube" railway equipment is shown in the next slide, already shown pictorially. In this the cars provide five commodious seats and standing room for three extra passengers in each. Thus at the normal minimum speed of three miles per hour, the capacity is 9,900 seats per hour plus 60 per cent. standing capacity. The speed ratio is eight to one, so that the maximum speed is twenty-four miles per hour normally. Thus, if the distance between stations be one half-mile, as usual on the London tubes, the schedule speed of twenty miles per hour* would be provided. Obviously, in point of attractiveness, it is preferable to have twice as many stations per mile of route, viz., at 440 yards intervals, and in that case the schedule speed will be sixteen† miles per hour. This is at least as good, if not better, than the train system can maintain satisfactorily even with only two stops per mile.

It will be noticed that the entire equipment for this great capacity in each direction can be conveniently accommodated in a single 16 ft. diameter tube. Now bearing in mind the very much shorter stations, and the far less accommodation required at the route ends, terminal yards, cross-overs, etc., and considering the much lower capacity of a tube railway, it is obvious that the Adkins-Lewis system requires very much less constructional accommodation.

* See pamphlet containing reprint of these articles.

* This is 25 per cent. to 30 per cent. better than the train system can accomplish on routes having two stops per mile.

† The train system cannot maintain more than twelve miles per hour on a route having four stops per mile, and then only at such a high cost that such a service would be commercially impossible in London at present fare rates.

Hosted by Google

Mere capacity, however, is not the correct basis of comparison between various systems. The earning power of a transit system, or at least its attractiveness, is a function of the number of seat-stops per hour that can be made at stations along a route. Designating this factor as "X," and figuring out "X" per square foot of property required, or "X" per £1,000 of capital cost, which is the more correct basis of comparison, it will be found that the Adkins-Lewis system possesses astounding advantages over the train system. Compared with the District Railway at maximum service, in point of the intensity to which it can use its tracks or clearance width for the passage of its trains, the Adkins-Lewis system will be found to be capable of subjecting its trackway to at least four times the intensity per unit area. This is a very important point, considering that the greater part of the outlay or the train system is represented by its tunnels, tracks, stations and similar items. Obviously the greater use to which this expensive property can be put, the less may be the fares and the greater will be the returns. Time does not permit of treating this and other interesting matters as fully as the author would like, so let us pass along to the question of capacity regulation.

It is recognised that if at the time of most dense* traffic, a railway has to pass, say, 12,000 seats, or 40 six-car trains per hour, the average for 365 eighteen-hour days will only be about 5,000 seats per hour. To meet this condition, the railways either increase the number of trains per hour or vary the make-up in cars, but the best they can do necessitates their running about three seat-miles per passenger mile secured in fares, and even this involves too much "straphanging" at times.

Now, varying the number of cars in service, more or less, in accordance with the demand, means that the annual mileage per car does not usually exceed forty or fifty thousand miles, and, whilst it is better to keep them idle than running around empty, it also means the provision of huge storage sheds at the terminal yard. Were it not that a large saving in wages of train crews and power consumption is thereby effected, it might be as well to keep the full complement of rolling-stock in service, since the increase in depreciation would be largely offset by the saving in car-sheds and the expenses attending the provision of the extra train crews, etc.

Let us here revert to the continuous system. The extra cost involved by keeping the full complement of cars in service, since they do not require train crews, and since they consume but little power, also since the depreciation and maintenance charges are so comparatively insignificant, does not warrant regulation of capacity to meet the demand by varying the amount of rolling-stock run. It can be done in a very much simpler way, by merely varying the speed. Thus on Sundays and slack periods of the day, a reduction of 25 per cent. in speed would still enable a schedule speed of twelve miles per hour to be maintained on a route having four stations per mile, and even this would be considerably better than existing services in point of effective speed, as shown in Figs. 1, 2, and 3.

Thus, upon the introduction of the continuous system, the very low speed of two miles per hour could be adopted and speeded up as the public became accustomed to it. In this connection, note that the capacity increases proportionately with the speed. Consequently, a route equipped with the Adkins-Lewis system could take care of traffic growth, within very wide range, because, when the initial speed becomes too high, subsidiary platforms could be installed at the stations to enable passengers to negotiate the cars in two stages on the lines of the multiple-speed moving platform previously described. The possibilities in this direction are worthy of note, but need not now be discussed.

Although smaller capacity would probably be found sufficient in many cases, let us consider the detailed designs for the greater capacity of 12,680 seats per hour with initial speed of three miles per hour, or 8,500 seats per hour with initial speed of two miles per hour, shown in the slide. In each case, the overload is 50 per cent. standing capacity. The complete two-track equipment with side walks requires only 17 ft. width in the clear and 13 ft. depth. A 16 ft. diameter, or at most a 17 ft. diameter, tube would be sufficient for runs between stations,* which would have 10 ft. wide platforms. The next slide indicates the general arrangement of details. The cars are eight-seated, their bodies being readily removable from the trucks, which are coupled by a yoke permitting each to take any curves by the guiding action of the thrust-rollers travelling in the central chase. The forward truck carries the double-

* See footnote † on second column of p. 107.

* The tracks need not necessarily be close together and accommodated in a single tube. They can be separated to any extent, so that each track could be accommodated in a small diameter tube, and two small tubes would be cheaper to build than one large one of the same area.

engaging rollers very substantially; the running wheels, which are flangeless, are retained on their tracks by the central guide and thrust-rollers. Derailment is obviated by the provision of a tilting check operating against the edge of the guide tracks. Here it should be stated that the slightest derangement causing this check to come into action would close electric circuits, which would cut off the power supply to driving motors and quickly bring the system to a stop. One form of automatic gate is shown at the car entrances. It will be seen from the plan and elevations that this is operated, through the medium of a spring to prevent pinching, by a very simple arrangement actuated by contact with a side track.

The next slide gives the details of one form of shaft construction. The method of building this in hexagonal form with standard rolled steel trough sections is a great improvement upon the tubular core shown in Fig. 4. It will be seen that distance pieces are inserted between the sections, and the whole is heavily riveted together. One end of these distance pieces is extended to carry and secure the spiral, and where the spiral pitch is close, three such fastenings per convolution, whilst six per convolution where the pitch is spread out, are found to be amply sufficient. The shafts are built up in lengths of 44 ft., and the joints are triple-scarfed as shown, bolted up by heavy turned bolts fitting drilled holes slightly oval to permit of expansion and contraction. In this connection it should be remembered that, as the temperature of subways does not vary more than 10° to 15° all the year round, the amount of expansion and contraction is extremely small, and can be satisfactorily provided for in the manner shown. The spiral consists of a stout rail or bar-section of more than ample strength. It is easily made to great accuracy by simply winding on a mandril in convenient lengths, which are fish-jointed together after mounting. The diameter of the shafts for the speeds required is 24 ins., when the spiral pitches vary from 12 ins. to 96 ins. Thus at 264 revolutions per minute constant shaft-speed, linear speeds of three and twenty-four miles per hour are given. The weight of the shafting complete, with bearing sleeves located about every 44 ft., carried in cradle roller bearings as shown, is about 110 lbs. per foot run. The cost per ton is obviously very moderate, as also is that for the entire equipment, including erection, seeing that all parts are light and portable, and largely repetition work.

Referring now to the next slide, we see how the rather sharp curve of about 70 ft. radius is negotiated. It has already been explained that where the spiral pitch is close the cars congregate together, and, if necessary, can be made actually to touch each other. Obviously, then, the spirals can be eliminated. The car engaged with the last few close pitch spirals on the one shaft will push the cars ahead of it over the gap and into correct engagement with the first spiral convolution on the next length of shafting. It does not matter if the gap comprises a straight run or a curve. The force necessary to push even a considerable number of cars around such a curve is a mere bagatelle, the speed being low and the track level. Although quite possible, the negotiation of curves at high-speed sections is unnecessary, because wherever a curve is necessary it would not be inconvenient to locate a station. Advantage is taken at such points to introduce the driving motors as shown—*i.e.*, at stations every quarter of a mile along the route—the shafts being enormously over-strong to transmit the power required without appreciable distortion.

Similarly, as indicated in the slide, changes of grade are negotiated. The diagram shows a station located at the top of a hill with a 5 per cent. grade on each side. The arrangement will be seen to comprise the simple application of a pair of conical gears interconnecting the driving shafts through the station gap by means of a horizontal length of ordinary plain shafting taking the driving motor, thrusts, etc.

The next slide shows two arrangements for negotiating the angle at the bottom of the grade. The actual coupling of the two shafts is effected by a pair of bevel gears. The thrust is transmitted through the centre by an ordinary spherical ball and cup, which is quite satisfactory considering the very small amount of oscillating movement existing. Now a little thought will reveal that if the driving shafts are so designed as to accelerate the cars down the grade, and to retard the cars going up the grade, the thrust due to car reaction can be practically balanced out. Still, even if this feature be neglected, the total thrust due to both car reaction and weight of shaft and cars on the incline would not be greater than could be adequately provided for by the simple means above described. But there is another provision, as shown in the slide, from which it will be seen that advantage may be taken of the gaping taking place on the bottom side of the thread, due to the angularity, to insert a thrust-bearing. Another point to be noticed is that although the ends of the spirals gape open on the bottom side of the revolution, they match

Hosted by Google

up exactly on the top side where the engagement takes place. Thus, notwithstanding that at the point of change from inclined to horizontal shafts the speed will be at the maximum value, the engagement will have a continuous thread throughout. Although the joint in the spiral will not be fish-jointed at that point, the cantilever formed by the ends of the spiral will make the thread actually as strong as it is anywhere else, and the strength of the bar forming the spiral is always amply in excess of requirements.

proposition is before you, substantiate the claim that 80 per cent. of the kinetic energy would be returned to the system during deceleration on level tracks. The actual efficiencies of the driving device for various angularities are given in Fig. 6, the dotted curve giving the reversed efficiency. It will be observed that the efficiency in both directions is in the neighbourhood of 90 per cent., their product again indicating about 80 per cent. regeneration.

Now let us dip into the operating details.

Table. Efficiency of Varying Pitch Screw Driving Shafts

Position	Pitch	Angle "A"	Angle "ϕ"	Efficiency	Remarks	Formulae
Slow Speed	12″	9°·25″	1·10	89%	A = Angle of Thread	
Acceleration	12″ to 96″	9°·25″ to 52°·0″	1.10 1.10	89% to 95%	Average Efficiency 92%	$E = \frac{\tan A}{\tan(A+\phi)}$
High Speed	96″	52·0	1·10	95%	ϕ = Angle of Friction	
Retardation	96″ to 12″	52·0 to 9·25	1·10 1·10	95% to 87%	Average Efficiency 91%	$E_1 = \frac{\tan(A-\phi)}{\tan A}$
The return of Kinetic Energy to Shaft during Retardation = ·92 × ·91 = 83·75%						

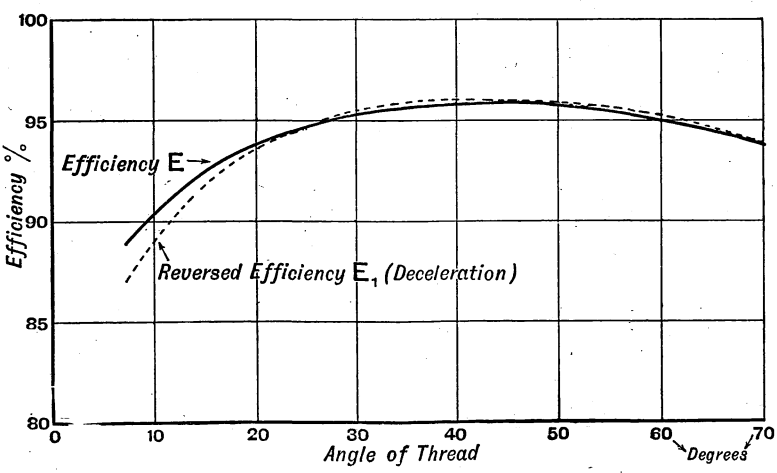

Fig. 6.—Efficiency of the Adkins-Lewis Driving System.

It is interesting to note the rather curious fact that the introduction of grades and curves on a route equipped with this system obviously tends to reduce the cost of the equipment. Grades also have the effect of minimising the forces necessary to produce acceleration and deceleration, and furthermore are clearly regenerative. Apart from the action of grades, however, the driving device is highly regenerative. Actual tests conducted at Ipswich by Mr. Hobart, whose general report* on the Adkins-Lewis

First, as to power consumption, lubrication, and maintenance of bearings. Any doubts as to the practicability of the Adkins-Lewis system on these points will be at once dispelled when the capabilities of ball and roller bearings are appreciated. These types of bearings have now reached such a stage of perfection and reliability that they can be absolutely depended upon when applied under proper conditions. It so happens that the conditions prevailing in this system are ideal for either ball or roller bearings. The loads and speeds are well within the limits. The

* See Appendix, p. 123.

Hosted by Google

leading makers assure the author that these are much below their normal standards, and further that lubrication will be only a matter of charging the bearings with grease but once in six months, and, more important still, that the bearings will not begin to show any depreciation at all for the first ten years, since they can be made absolutely dust-proof. Ample evidence in actual practice can be furnished in support of these favourable prospects, but the author in his estimates makes very much more conservative allowances, even such as are appropriate to ordinary bearings. Yet, as can be shown, the results come out so favourably that his claims are fully justified.

As regards the power consumption, a quite simple calculation upon data very conservatively applied against the system when operated at a capacity of 12,672 fully loaded seats per hour, at a schedule speed of sixteen miles per hour on a route having four stations per mile, shows that only 200 kilowatts input per mile of track is sufficient to cover the total consumption for lighting, car propulsion, shaft rotation, and thrust, and all losses including the motors. Thus the energy per seat-mile would not exceed 15 watt-hours in ordinary practice. This is only about one-third of the amount found to be necessary in train practice, when there are but half as many stations per mile. Bearing in mind the uniform nature of the load, and the consequent lower cost of power per unit (especially if Diesel engines be used in its generation), the relatively greater amount of power consumed in brilliantly lighting the route throughout as proposed, does not vitiate the claim that, compared with electric trains, the Adkins-Lewis system can provide an equivalent service for less than a quarter of the power consumption per seat-mile, neglecting lift and other incidentals to tube railways altogether.

Time does not here permit of a detailed investigation of the operating cost, but seeing that the services of train drivers, conductors, signalmen and liftmen are entirely obviated, and further that both skilled and unskilled labour, superintendence and establishment, and all charges in general, are reduced to comparative insignificance, it is obvious that the gross operating expenses will be but a small fraction of those necessitated by the train system.

It is difficult to generalise in the matter of both capital and operating cost, but the table on pages 120–121 is given as a rough indication of results in comparison with various existing systems. Carefully-prepared estimates indicate that the capitalisation ought not to exceed one-half that of the more recent tube railways, on the same basis of composition: thus in the table £300,000 per route-mile is taken.* As regards gross operating expenses, the figure of 0·04*d.* per seat-mile appears to be well on the safe side. The table, which is self-explanatory, will, it is believed, clearly show that the Adkins-Lewis system is particularly well suited for the dense traffic usual in the central area of all great cities, and that it can do in many ways more than any existing system can ever hope to do.

It only remains to consider the question of wear and tear, the safety factor in component parts of the equipment, its general behaviour when at work, and lastly the feasibility of the continuous plan for public service.

First, then, as to wear and tear. Take the cars. Their dead weight is about 350 lbs. per seat; therefore there is only about one-third the amount of rolling-stock subject to depreciation that there is in the train system for equivalent schedule speeds and capacity. The car bodies are relatively quite as strong, but there is less vibration, and the stress coming upon them is decidedly less severe. Their trucks carry no complicated electrical equipment, nor is there the usual noisy air-compressor for the brake system, because no brakes are required. Thus the running wheels, which are flangeless and carry but light loads, will have a long life and will run easily. The whole car, including the automatic gate or door operating arrangement, is of the simplest possible character, substantial in construction, and with low centre of gravity —all tending to endurance and low initial and maintenance cost.

Now as to the tracks. The rolling loads are so light and well distributed that the usual heavy rails can be substituted by either a light steel bar section, or fibre or even rubber, set upon longitudinal timbers, thus securing comparative noiselessness. The central guide and thrust tracks are subject to practically insignificant loads, so that these parts do not appear likely to give any trouble.

Now we come to the wear and tear of the edges of the spiral and its pair of engaging rollers. Here it may be pointed out that the proper working of the engagement is not affected by slackness to almost any extent between the thread and its engaging rollers, and that there

* Note that the capacity taken is far greater than that of the tubes, and that there are four stations per mile as against two.

REMARKS AN

All interested in the London traffic problem and exponen

COLUMN 3.—See London Traffic Branch Report, 1910, page 6. The coefficients adopted have been criticised as unfair to tramways.

COLUMN 5.—The vast majority of journeys about London average two miles. In the central area the average is no doubt less. Tendency is towards shorter journeys, except in the case of rush-hour journeys to suburbs—increasing length.

COLUMN 6.—See Figs. 1, 2, and 3, and note effective speeds for journeys of one mile. "A & L" speed reduced 25 per cent. on Sundays a holidays, and slack periods of week days, the running time per day being taken at eighteen hours.

COLUMN 7.—See text. All present services are overcrowded during "rush-hours," and there is too much "straphanging" on railways. There could be no overcrowding nor straphanging on continuous system, as it is so capacious.

COLUMN 9.—The tendency is towards an increase in operating cost, especially in the case of trams. If in the train system the seat milea be increased two and a half times to correspond with the "A & L" system figures, the gross cost per seat-mile would be reduced about 0·123*d*., or about 30 per cent. The figure 0·04*d*. given for the Adkins-Lewis system might be considerably reduced.

COLUMN 10.—These figures vary according to class of route. * The allowance of six seat-miles per passenger-mile for "A & L" is high.

COLUMN 12.—The tendency is towards higher fare ratings on all railways. This is not conducive to general welfare.

COLUMN 13.—The future for L.C.C. tramways is decidedly bad. The prospect for the sub-surface railways is bright, whilst that for moto buses is still better, provided that increased street congestion will be tolerated.

COLUMN 14.—There are several routes in the heart of many large cities which would support a really first-class facility with returns of twel million one-penny fares per route-mile, especially if the unit fare covers any distance. Tubes lose most of the lucrative "short hau traffic to buses. † Tube's average fare per passenger is about 1·8*d*., indicating average length of journey of three miles.

XPLANATIONS. *Attention should be confined to the dense traffic in central area.*

f the various systems are invited to criticise freely.

OLUMN 15.—Profits per route-mile may be considerably higher owing to slightly greater profits per passenger-mile than shown in Column 13.

OLUMN 16.—Figures given for trams and buses are too high for new concerns. L.C.C. and L.G.O. heavy capitalisation is due largely to previous animal-traction. The capitalisation of tubes was over-inflated, heavy parliamentary and incidental expenses for such facilities are detrimental to public benefit. Capitalisation given for continuous system should be ample on same basis as tubes. Smaller equipment would provide as good a service and be adequately capacious in many cases, so that superior returns could be made.

OLUMN 17.—Bus returns are based on L.G.O. figures for year ending September 1910. Trams on L.C.C. Report for year ending March, 1911.

OLUMN 18.—See note to Column 9. The bus companies can considerably reduce their operating cost by increasing bus mileage. The L.C.C. already work their tracks to an intensity far more severe than is usual, and apparently cannot increase mileage per track mile.

OLUMN 20.—See text. The number of seat-stops per hour per route-mile is a measure of the attractiveness of a facility.

OLUMN 21.—Values given have been assigned after consideration of following points to make a fair comparison of systems :—
Speeds=Schedule "Street to street" and "Door to door." See Figs. 1, 2, 3.
Capacity=Maximum rush-hour service, loading capacity per station, overload, average over 6,210 hours per annum and growth.
Comfort=Vibration, swaying, acceleration and deceleration, noise, ventilation, ticket troubles, protection from weather.
Reliability=Safety, freedom from delays, labour troubles.
Economy=Initial costs, operating cost, fares, return on investment.
Efficiency=Street obstructiveness, space requirements, flexibility, accessibility.

OLUMN 22.—The claim that the Adkins-Lewis system is only from two to four and a half times superior is very moderate.

Hosted by Google

can be an ample margin of stock in the width of the spiral bar to cover any amount of wear that is likely to take place in many years. Consider the pressures that the spiral exerts against its engaging rollers, and *vice versa;* for the leading roller alone is engaged during the propulsion and the trailing roller only during retardation. The pressures are extremely small. Assuming the cars weigh two tons fully loaded and that the tractive effort is assumed at the high value of 10 lbs. per ton* on the level, it will be seen that for uniform speed sections, constituting about 70 per cent. of the track length, the pressure is only about 20 lbs., whilst for the remaining 30 per cent., comprising the acceleration and deceleration sections, this pressure is gradually increased and decreased in the case of level tracks to a maximum of possibly 1,000 lbs. Even this is not serious, and would be greatly minimised by the use of grades as previously indicated. Of course, an entire route may be graded all the way,† but the pressures would still be low.

In the consideration of these various points relating to wear and tear, it should be borne in mind that all the component parts are repetitions of but a few standards, and that naturally they would be made to gauge. All parts are readily "get-at-able." Even a length of shafting could be removed and replaced within a couple of hours, and there would be six hours every night and a longer period on Sundays for inspection and rectification, lubrication and cleaning.

The second item remaining to be dealt with is that of the safety factor. In this respect the system, as a whole, lends itself remarkably well in every detail to the provision of exceptionally high factors of safety without detriment in other directions. The chances of breakages of any parts are extremely remote, possibly more remote than is usual in railway practice. Yet flaws in metal parts are recognised to be possible—indeed, even inevitable. Then let us suppose that the obviously most vital part, viz., an engaging roller spindle, gave out. What would happen? It could drop on to the shaft, and then be very promptly thrown away to the side by centrifugal force, without doing damage, whilst the car would still be controlled by one roller. The free play it would have would only be 8 ft. at maximum pitch, so that no serious consequences would result. Such a breakage could be as safely guarded against as a broken axle on a railway train, and remember that electrical means could be provided to indicate the slightest derangement of any part. Perfection is not claimed for the system, nor are the designs shown in this paper either final or even the latest.

The third point relates to the behaviour of the system in working order. Of course this, as well as the two preceding points, can only be determined by actual trials upon a full-size equipment, but as regards the question of noise, it may reasonably be expected that, with "Citréon" gears, the cradle roller bearings suitably mounted, and other precautionary measures, noise will be practically eliminated. Anyhow, it will be far less than prevails in trains and trams. The riding of the cars will undoubtedly be far more free from vibration and swaying than in those cases. Ventilation and other considerations also can obviously be dealt with in satisfactory manner.

The author will close by referring to the feasibility of continuous transit. The question is not whether people can step on and off a moving way; no one doubts that anyone who can walk at all can step on and off a glacier, for instance—truly a moving way. The question is, What is the highest speed that can be negotiated by passengers who are agile enough to escape being killed by the present street traffic? Common-sense indicates that it is at least three miles per hour. Results from actual practice prove it beyond question. Necessity demands it, because there is no alternative way through the *impasse* which has been reached. Finally, it may be asked, Is it not worth a great effort to render possible the introduction of a system having such pronounced advantages? The author respectfully submits on behalf of his friend and associate, Mr. B. R. Adkins, who is equally responsible with him for devising the Adkins-Lewis system set forth, that it is. Both feel grateful to the Royal Society of Arts and to the audience for this opportunity of submitting the proposition; and to Messrs. Ransomes & Rapier, Ltd., for valuable assistance rendered in carrying out numerous and costly experiments and building a trial transporter nearly forty yards long, having a capacity of 2,000 to 3,000 passengers per hour and speeds up to ten miles per hour, from which valuable practical results have been obtained; also to Professor Dalby, Mr. Hobart, Captain Sankey, Mr. Basil Mott, Mr. David Hay, and to others who have kindly encouraged them.

* The tractive effort, including air resistance, is not likely to exceed 6 lbs. per ton on level tracks.

† The "up" track would be largely balanced by the "down" track.

APPENDIX.

GENERAL REPORT ON THE ADKINS-LEWIS SYSTEM BY MR. H. M. HOBART, M.INST.C.E.,

Consulting Engineer to the General Electric Co. of New York.

OSWALDESTRE HOUSE,
NORFOLK STREET, STRAND, LONDON, W.C.
February 22nd, 1911.

Messrs. ADKINS AND LEWIS,
49, Queen Victoria Street, London, E.C.

DEAR SIRS,

Re THE "A & L" SYSTEM OF RAPID CONTINUOUS TRANSPORTATION.

During the last six months I have made a thorough examination of the propositions comprised in the "A & L" system of passenger transportation, and have made tests of the experimental machine at Messrs. Ransomes and Rapier's works at Ipswich. I have made investigations in which I have compared this system with the electric train system of passenger transportation as employed in tubes, subways and elevated roads in large cities.

As a consequence of my investigations, I am satisfied that the "A & L" system is based on thoroughly sound and practical principles, and that both as regards capital and operating costs, a specified result can be obtained much more cheaply than by the electric train system. While this is also the case for such long average runs as one mile between stations, the balance in favour of the "A & L" system becomes greater the more frequent the stops, until for such a case as an average distance of one-quarter of a mile between stations, while the "A & L" system can, with profit, operate such a service, providing a schedule speed of over fifteen miles per hour, this is commercially an impossibility with the electric train system, as with an average of four stops per mile, the highest practicable schedule speed which could be provided by the electric train system is twelve miles per hour, whilst the cost of providing such a service would exceed any return which could be obtained. With an average of three stops per mile, an electric train service begins to assume commercial practicability, but the capital cost is so great, and the return to the investor is so small (as also with only two stops per mile) that developments on these lines have during the last few years been practically at a standstill.

It is difficult to generalise in the matter, but the total capital investment for typical urban instances is, with the "A & L" system, very much less than the capital investment which would be required for an electric train system. The operating costs are also much lower with the "A & L" system than with the electric train system. The much lower initial and operating costs will permit of materially lower fares than are feasible by other methods of passenger transportation. This, together with immunity from delays, greater schedule speed and the features of comfort and safety attending the "A & L" system, should secure a large traffic to a route equipped on your system. The low costs and heavy traffic should yield an excellent return on the investment, notwithstanding the more moderate fares. With the electric train system, a reduction of fares below the present level would not increase the traffic sufficiently to increase the present unsatisfactory return on the investment, and higher fares would drive traffic to buses and trams in the streets.

Thus in the case of the roads already equipped with the electric train system there is no choice but to await the natural growth of the traffic. Although this natural growth is in several cases leading to a gradual slight improvement in the net earnings, there are certain cases where it is proving impossible to effect any improvement. Consequently although London's development requires an immediate large increase in rapid transit facilities, capital is not likely to be invested to any notable extent in electric train systems. There are also several large provincial cities which, whilst urgently needing rapid transit facilities, are unable to secure them owing to the enormous capital cost. My opinion is that in the "A & L" system these difficulties are very satisfactorily overcome, and although I have investigated the system very thoroughly I find no feature (other than faulty details associated with experimental machinery which are susceptible of obvious remedies) which should stand in the way of its practical and commercial success for the purpose of urban passenger transportation.

Amongst the fundamental principles contributing to the success of the "A & L" system, I attribute much importance to four valuable features, namely:—

1. The provision of a continuous succession of cars, moving slowly at stations and at high speed *en route* between stations. I am, after careful investigation, satisfied with the feasibility of the continuous principle in public service.

2. The perfection of acceleration secured owing to the graduation attainable in the driving system. This permits of attaining higher acceleration and deceleration, and with greater regard for the comfort of passengers, than is practicable with electric trains.

3. The excellent regenerative features of the system coming into operation during deceleration of the cars on approaching stations, whereby a large saving in power consumption is effected, and all braking devices with their attendant wear and tear are eliminated.

4. The elimination of the necessity for any signalling system, notwithstanding which, even greater safety is secured than is possible with the most comprehensive signalling systems yet developed for the control of electric trains.

Yours faithfully,
H. M. HOBART.

DISCUSSION.

The Chairman (Captain Campbell Swinton), in opening the discussion, said that to him there was something extraordinarily fascinating in the idea that when a passenger wanted to travel from one part of a city to another he simply had to step down under the pavement and always find a means of transit waiting for him. About three years ago he put forward a proposal in an article in the *Nineteenth Century* of a method of transportation by means of a moving platform to cope with the difficulties of the traffic in the City. The City traffic required to be treated in an entirely different way from the rest of the traffic in London, as it was practically continuous for twelve hours in the day; and he proposed that a subterranean road should be made from, for instance, the Mansion House Station to Liverpool Street Station in the form of what he called a double-gourd, with a neck at the back. He did not know at the time how such a suggestion could be carried out, but the author had now put forward a proposal by means of which it could be done. The question that always arose, however, was whether people would use such a means of conveyance. Subways had been made at a great many places in London, but people would not go down into them unless they wanted to go to a railway. Then the question arose in his mind how such an automatic moving platform could be stopped. People would commit suicide, or they would get into dangerous positions; and in view of the fact that the author had stated that one of the advantages of his system was that very few officials would be required, it would be interesting to know how the service would be stopped if somebody threw himself underneath a car. The author seemed to suggest that some electrical appliance would ring a bell and that somebody somewhere would stop the system; but it appeared to him that there would be a very small chance of picking up many bits of the unfortunate person who happened to fall on the shaft. Another question he desired to ask the author was whether anything would be done to prevent a person who chose to pay his fare staying in the car for as long as he liked, and going round and round the circle. He was also informed by an engineer that there was a possible danger of the people who rode on such a railway being deafened by the noise. He had been on the London County Council for ten years, and had obtained a good deal of knowledge of the difficulty and cost of making tramways and subways in London. For instance, it cost at the rate of £37,000 per mile to lay the four tramway rails and two conduits, which only went down 2½ feet, in Theobald's Road. The author proposed to place his system underneath the pavement; but personally he remembered that when some years ago it was suggested that shallow trams should be made along the Strand it was pointed out that most of the houses in that thoroughfare possessed cellars underneath running almost to the middle of the street; and the County Council was informed that if a tramway was put there, according to the law at the present moment, if they bought the cellars they would be compelled to buy the houses as well. The inconvenience which would be caused while the system was being constructed was another difficulty. The London tubes had been made practically without people knowing anything about them, because they were right down in the London clay, and it was possible to construct them without incommoding anybody; but those who had watched Kingsway being constructed, and had seen the numerous kinds of pipes, tubes, sewers, and various other connections which had to be supported while the road was being made, and eventually put back again on the same level, knew the enormous difficulties that had to be dealt with. He was perfectly clear in his own mind that the proper place to install such a system was in a locality where an enormous number of people wanted to travel with the least possible trouble, such as, for instance, the City of London; and if the author could induce the Corporation to take up his scheme he might be able to make some progress. But the installation of such a system meant the spending of a great deal of money. The place in which it could be most easily installed at the lowest cost, was one of the London parks, but in that case probably there would not be sufficient traffic to make the railway a paying concern. For instance, right down Park Lane going to Victoria he doubted if there was sufficient traffic to make the construction of a railway a commercial proposition. Since the previous morning a new capital city had been born in the Empire, Delhi, where a new city was to be laid down on absolutely new lines. It would be an extraordinarily easy thing to lay down a system such as the author's in a new city, while it was an extraordinarily difficult thing to lay it down in an old city like London. The question was one very much of pounds, shillings and pence, and he sincerely trusted the author would find somebody who was prepared to put down sufficient money for the purpose of erecting a specimen system.

Captain H. Riall Sankey said that he had seen at the works of Messrs. Ransomes and Rapier the model transporter referred to by the author, which was about 60 ft. long, with bends at each end, and would carry 5,000 people per hour; and one of the most remarkable points in connection with that model installation was the enormous rate of acceleration attained, namely, 4½ ft. per second per second—just about three times greater than that attained on the District Railway. Notwithstanding that enormous acceleration, it was possible to stand up in the car without holding on to anything, and the passengers were not thrown down. The reason for that result was that the screw thread was perfectly developed on a proper curve, so that the acceleration was gradually increased and decreased. He also, while at Ipswich, took a few rough measurements, which satisfied him that the figure given by Mr. Hobart with regard to the return of

Hosted by Google

energy was substantially correct; while he was also able to vouch for the accuracy of the other figures given by the author. One criticism frequently made against the use of such a transporter was that it was impossible for people to get in and out of cars moving at three miles an hour. He admitted that possibly 10 per cent. of the population could not do so; but it was not logical to argue that the remaining 90 per cent. of the population were to be debarred from using such a means of transportation for the sake of the minority. Another objection he had heard raised was that in the case of a family travelling on the author's system, the grandchildren would find themselves in one car and the grandparents in another.

Mr. Wilfred Stokes said that when the author first brought his system under his notice he treated it as a wild-cat scheme; but the more one studied the proposition the more one appreciated its charm. He did not think anybody could question that continuous transportation was much better than intermittent; and once the question was decided whether people could get in and out of a moving car, it seemed to him the system was so much better than train service that it should be given a trial. It might be said that a long, comparatively heavy screw revolving continuously was not a very fine mechanical contrivance compared with the present train service, but he thought it would be found on mature consideration that much more energy was wasted in the operation of driving an ordinary train than in keeping a screw revolving. He asked those present quietly to think over the scheme the author had brought forward, and he was sure they would come to the conclusion that there was a great deal more in it than appeared at first sight. In spite of the derogatory remarks that were made about motor-cars and flying machines in their early days they had become a great practical success, and he could not help thinking that the author's scheme would be successful in the same way. As an engineer, he expressed his great admiration for the ingenuity Mr. Lewis had displayed in solving many intricate problems.

Mr. Llewelyn B. Atkinson thought the system had now reached such a stage that nothing further could be done with it until it was given a practical trial. He had known Mr. Lewis for many years, and he felt sure that any scheme which he put forward would be worthy of the most careful consideration.

Mr. W. Mair, as an expert in connection with ball bearings and suchlike mechanism, assured those present that the author's figures with regard to the efficiency of roller bearings were absolutely correct. The manufacture of such bearings had been developed to such an extent in recent years that frictional loss was now practically a thing of the past. With a bearing made on the system designed by the author, there would be a saving of about 80 to 90 per cent. of the power used, as compared with any other kind of bearing.

Mr. R. P. Brousson said he thought, in justice to the existing methods of transport, it was not an unfair criticism to say that the author had emphasised the disadvantages of the existing systems. The author had not been quite fair in comparing his system with the present tube railways, because he assumed his system was placed in a shallow subway. There were great difficulties, however, in London in constructing such a subway, because of the pipes, wires, and cables that existed near the surface. A fairer basis of comparison would be to assume that the "A & L" system was a deep subway system. It was his own view that some form of moving platform or inclined elevator applied to the tube railways was becoming more and more essential, and it was only a question of time when the present lifts would be replaced by such contrivances; and when that day arrived a large amount of the delay which at present existed in getting in and out of the tubes would disappear. The author had assumed that the traffic stream was a uniform and a continuous one; but personally he considered that was a fundamental fallacy. The traffic in London railway stations was not continuous and uniform. For instance, at Finsbury Park, where the tube connected up with the Great Northern system, the officials were confronted with the problem of dealing, during the busy traffic hours of the morning, with batches of two hundred or three hundred passengers delivered on to the platforms in thirty seconds, and the author's system was at present incapable of dealing with such an aggregate of passengers without delay. For instance, at three miles an hour through the stations, he estimated that if the author had on his system about five seats available to every ten feet, his capacity would be about eight thousand seats per hour, and that was useless under present conditions, because one had to deal, not with an average, but with the maximum peak of traffic obtained not in an hour but in any five minutes. The maximum capacity of the electric train service on the District Railway was at present an eight-car train every 1¼ minutes, with an average speed of 16 miles per hour. It was an interesting point to compare the amount of track that was occupied in an ordinary electric train service with that occupied by the author's system. 23·7 per cent. of the track would be occupied by trains with the service he had just mentioned; whereas on the author's system, assuming the stations to be half a mile apart and the maximum speed 18 miles an hour, 27 per cent. of the track was occupied. It would therefore be seen there was not any great difference in the two capacities if his figures were fairly accurate. The author had assumed on his diagrams that he would have two seats side by side, whereas

on the present electric stock there were four seats transverse at a time, with the result that with the electric train service he had mentioned at least twice the carrying capacity could be obtained compared with that of the author's system. Immediately an attempt was made to get the same number of seats as in an ordinary train, it was necessary to have large tunnels, which meant that the cost would be very heavy if it was necessary to have a bigger capacity than at present existed. After all, the capacity of a system was the rate at which it was possible to load; and it would be found in all the London traffic systems that most of the passengers got in or out at one or two stations in the City area; and that it was necessary to provide facilities at those stations for loading or unloading almost the maximum capacity of the train: it could not be spread over a large number of stations. Turning to the question of mechanical details, while the author's system was certainly most ingenious, there was no flexibility in a moving platform beyond the question of varying speed. As the ratio of the traffic in the middle of the day compared with the morning and evening was 1 to 10, and very often 1 to 20, if the train was to be loaded to its proper capacity it would be necessary to reduce the speed ratio 1 to 20, which was impossible. Therefore there must be a large number of idle seats, because the peak load in an 18-hour traffic day was confined to 4 hours. For 14 hours the system ran at a comparatively light load, and with the present method of electric service it was possible to adapt the cars approximately to the number of passengers that had to be carried. Although he agreed that there probably would be a considerable gain in efficiency with the author's system, compared with the ordinary electric system, nevertheless, owing to the fact that the power consumption was constant through the traffic hours, the gain in power consumption would not be so great as was apparent. When a practical railway engineer first studied such a system as the author's he was alarmed at the thought of hot boxes, hot worms, car bearings, and so on; while it appeared to him there would be a tremendous rattle and din with the gears and roller clutches for propelling each car. The noise on the present tube railways was quite sufficient.

Mr. Yorath Lewis, in reply to the Chairman's criticisms, said it was practically impossible for a suicide to take place on his system of transportation, as it was impossible for anyone to get in front of a car; and there would be plenty of room in the cars for any loafers who wanted to ride round and round the circle. He was quite satisfied that the system would be practically silent. The gear, roller bearings, and ball bearings were silent; the cradle roller bearings might make a little noise, but it would be negligible. In comparison with a tube railway the noise would certainly be insignificant. With regard to the question of street obstructions, he knew "that numerous pipes, wires, and sewers" were underneath the streets of London; but, as he had shown in the plan, it was not proposed with his system to disturb the roadway. The stations could be accommodated under the pavements, which were mostly occupied by basements, and which could be bought very cheaply from property owners, because in most cases they would be only too glad, from a business point of view, to have a subway station on their premises. By grading to a lower level and curving, it would be possible easily to clear most of the obstructions. Personally, he thought there was a fine opening for the construction of the system he advocated between Piccadilly Circus and the City, and the Marble Arch and Victoria, as he was advised by well-known traffic authorities in London that there was a considerable flow of traffic between these two points. That view was supported by the fact that the London County Council had been agitating for a subway for its tramways along that route. The idea of installing the system in Delhi was a most delightful one. Mr. Brousson had stated that his comparisons were unfair to tube railways. As a matter of fact, Mr. Hobart had, over a period of six months, compared the "A & L" system with tube railways, and had reported against electric traction and in favour of the Adkins-Lewis system. With stations a quarter of a mile, half a mile, and even longer distances apart, higher schedule speeds at a very much lower cost were practicable than with the electric traction system; in fact, it was impossible for electric traction to operate a road having four stations to the mile at a schedule speed of more than 12 miles an hour, and then only at such a high operating cost that it was not a commercial proposition with present rates of fare. The new system scored very heavily over the electric train system in regard to capacity; while it was possible to work the tracks to at least four times the intensity of service on the electric system. It was only necessary also to have one-third the rolling-stock for the same schedule speeds and capacity. The system was more flexible in some respects than a train system. He disputed Mr. Brousson's contention that the District Railway were now able to run an eight-car train every 1¼ minutes. They could only do that when they adopted Arnold's suggestion of island platforms as the author explained in his British Association paper. Mr. Brousson would prefer a more direct comparison between the Adkins-Lewis and the train system, both in tubes. Well, here it was. Electric trains, two stations per mile: Schedule speed, fifteen to sixteen miles per hour; time loss as at present between street and trains, six minutes, resulting in effective street-to-street speed of about eight and a half miles per hour for two-mile journey. Adkins-Lewis system in tube of same depth, two stations per mile: Schedule speed, twenty miles per hour; time loss between street and trains, two minutes; resulting effective street-to-street speed, two-mile journey, fifteen miles per hour. As to capacity, the Great Northern and City

Railway, which Mr. Brousson managed, had two 16-feet diameter tunnels for a rush hour capacity of about 6,000 seats per hour, whilst the Adkins-Lewis system would require only one of the 16-feet tubes for both tracks to give a seating capacity of 12,680 seats per hour. Fig. 3 in the paper indicated how the tubes could benefit by using continuous elevators. Mr. Brousson was quite wrong in saying that the author assumed the traffic stream was uniform. Let him read the paper. He was thinking only of his Great Northern and City Railway, which was merely a short rush hour feeder between the City and Finsbury Park Junction. It lost the day traffic to the surface trams and buses running on top of it because they gave a superior service, though their schedule speeds were only one-half that of the tube trains. There were several routes in all large cities, however, such, for instance, as along Oxford Street and between Piccadilly Circus and the City, where the traffic stream was fairly uniform all day, and of exceptionally large volume. The streams of traffic were always continuous, and ought to be handled by continuous instead of intermittent methods. Mr. Brousson's mental estimates as to capacity of the "A & L" system were quite wrong. Five-seat cars each 8 feet long gave a capacity of 9,900 seats per hour—and 8-seat cars 10 feet long gave 12,680 seats per hour. Even the rushes of 200 or 300 passengers in thirty seconds he mentioned could be easily dealt with from an "A & L" terminal with the lower capacity equipment as shown in the paper, whilst with the train system such conditions involved very distressing results. He said, after all, the capacity of a system was the rate at which it was possible to load. Mr. Lewis quite agreed, and that was where the Adkins-Lewis system scored very heavily over the train system. As to the amount of track occupied by trains or cars, Mr. Brousson needed a little more education on this point. He seemed to overlook the fact that the higher the schedule speed, the less will be the amount of rolling-stock required, and the less will be the percentage of track occupied for the same capacity, and here again the Adkins-Lewis system scored heavily. Moreover, when the intensity to which the trackway or property can be worked by various systems was considered, it would be found that the Adkins-Lewis system can subject its property to at least four times the intensity per unit area. As to the practical details, Mr. Brousson apparently was not well experienced in mechanical engineering—at least, in respect of the capabilities of ball and roller bearings, which were capable of running continuously without any temperature rise. His fears on these points were absolutely groundless, as they also were regarding "rattle and din," for there were no clutches, whilst the gear would be absolutely silent.

On the motion of the CHAIRMAN, a vote of thanks was accorded to Mr. Yorath Lewis for his paper, and the meeting terminated.

DURBAR HONOURS.

The following members of the Royal Society of Arts are among those who have received honours from the King on the occasion of His Majesty's visit to India, and in commemoration of the Coronation:—

K.C.S.I.

Maharajadhiraja Sir Bijay Chand Mahtab Bahadur, K.C.I.E., of Burdwan, a Member of the Council of the Lieutenant-Governor of Bengal for making Laws and Regulations.

Apcar Alexander Apcar, Esq., C.S.I., Consul for Siam in Calcutta.

G.C.I.E.

His Highness Maharaja Bhupindra Singh Mahindra Bahadur, Chief of Patiala State, Punjab.

K.C.I.E.

Lieutenant-General Sir Douglas Haig, K.C.V.O., C.B., Chief of the General Staff, Indian Army.

Rajendra Nath Mukharji, Esq., C.I.E., Sheriff of Calcutta.

Lieutenant-Colonel Percy Zachariah Cox, C.S.I., C.I.E., Indian Army, Political Resident in the Persian Gulf.

Francis Edward Spring, Esq., C.I.E., Public Works Department (retired), Chairman of the Madras Port Trust Board.

William Arthur Dring, Esq., C.I.E., Agent, East Indian Railway Company.

Raja Shaban Ali Khan, Khan Bahadur, of Salempur, Lucknow District, Oudh.

C.I.E.

George Cunningham Buchanan, Esq., Chairman and Chief Engineer of the Port Trust, Rangoon.

William Rucker Stikeman, Esq., Chairman of the Burma Chamber of Commerce.

Edward Robert Kaye Blenkinsop, Esq., Indian Civil Service, Commissioner of Settlements and Director of Land Records, Central Provinces.

John Ghest Cumming, Esq., Indian Civil Service, Secretary to the Government of Bengal.

Rai Sahib Diwan Amar Nath, Chief Minister to His Highness the Maharaja of Jammu and Kashmir.

Sardar Naoroji Pudamoji, ex-President of the Poona Municipality, Bombay Presidency.

Claude Alexander Barron, Esq., Indian Civil Service, Deputy Commissioner, Delhi.

Major Percy Molesworth Sykes, C.M.G., Consul-General and Agent to the Government of India in Khorasan.

G.C.V.O.

Lieutenant-Colonel Sir Arthur Henry McMahon, K.C.I.E., C.S.I., Secretary to the Government of India, Foreign Department.

KNIGHT BACHELOR.

Shapurji Burjorji Broacha, Esq., Sheriff of Bombay.

KAISAR-I-HIND MEDAL.

James Forrest Brunton, Chief Officer and Chief Engineer of the Karachi Municipality.

OSTRICH FARMING IN GERMANY.

The Hagenbeck ostrich farm at Stellingen, near Hamburg, was founded three years ago, and is growing rapidly in importance as well as in size. It was the theory of the proprietor of this farm that the ostrich, although a native of tropical or hot countries, would thrive in colder localities, and as a result be stronger in health and grow a heavier crop of feathers. During the three years that the Stellingen farm has been in existence this theory has been proved to be correct, although, for reasons to be explained, the enterprise has not been, from a commercial point of view, particularly successful. In South Africa, and in other warm countries, feathers are plucked regularly at the end of every nine months, this being the usual time required for the bird to grow a new coat. In Hamburg, however, according to the American Consul-General there, owing to the cold weather, the feathers can be plucked only in the spring of the year, the birds being housed in the winter months except on sunshiny days, and always at night. During these housing periods the feathers become broken, and while they are still of value they are less so than feathers plucked in good condition at the right season. The Stellingen farm holds two South African (Cape) female birds, two each from Senegal and Somaliland, and eight from the Blue Nile country, the last being considered the finest birds, and a species becoming very rare. There are a hundred or more birds of ordinary qualities grown from the egg in Hamburg. It is the custom to breed a cock bird having long, narrow, and very short feathers with a hen bird whose feathers are very weak but short and wide. In addition to the farm at Stellingen, the proprietor possesses one in German West Africa, and a ground has been purchased for a large farm at Piranto, near Trieste, the climate of which is considered most favourable. It is the intention to bring feathers from these two latter farms to the one at Stellingen to be manufactured for the trade. Up to the present, were it not for the entrance fee to tho Stellingen farm as an exhibition, the venture would hardly be a paying one. The incubator is used for hatching at Stellingen, but the hen-setting method is considered by all experts to be preferable. This latter method is not practised in Hamburg owing to the climatic conditions. There is some difficulty in hatching the eggs by means of an incubator, and close attention must be paid to avoid a total loss for the shells of the eggs are so tough that the young ostrich is unable to free itself, and help must come at the right moment from without. It generally takes about nine weeks to hatch in the incubator. Another peculiarity of a baby ostrich is that it will not eat when alone, and at the Stellingen farm there is a large size ordinary duck of a common breed which acts as foster-mother to all the young birds when first hatched.

CULTIVATION OF THE TEASEL IN FRANCE.

The teasel—fuller's weed, or fuller's thistle, as it is sometimes called—is still cultivated in France, though not so largely as formerly. During the last fifty years the area cultivated in that country has diminished about one-third in extent. In 1862, 2,326 hectares (5,745 acres) were cultivated with this plant; in 1882 this was reduced to 1,887 hectares (4,660 acres), and in 1909 to only 1,529 hectares (3,776 acres).

The substitution of metallic cards in place of the "burrs" of the teasel heads formerly used in the process of "fulling," or raising the nap of cloth and other woollen material, may account in some measure for this decrease. It is found, however, that the natural "burrs" of the teasel are more suitable than their metallic substitutes for the manufacture of certain classes of goods. This tends to maintain a demand for the heads.

In France, the teasel is grown chiefly in three departments. The areas cultivated, production and values in 1909 are given in the table below.

The teasel is also cultivated, on a small scale, in the Departments of Aude, Basses-Alpes, and Eure, but the production there is too insignificant to take into account. The plant is biennial, growing very slowly the first year, and flowering the next, in May and June. It thrives best in a light, gravelly soil, with a southern aspect, and well drained. In a very rich soil, the heads are apt to grow too large, and to be not sufficiently elastic.

The seeds should be sown in the spring, and the young plants kept well thinned out. In August they should be transplanted into rows about 12 to 15 inches apart; beyond weeding they require but little attention during the first year. Sometimes they are sown, like clover, with some cereal crop, and after harvest the plants are left in place, and simply weeded and thinned out.

In the following spring, as soon as the plants show signs of vigorous growth, and attain a height of 50 or 60 centimetres (1 foot 8 inches to 2 feet), the side shoots require to be removed, and the number of flower stalks restricted to eight to twelve on each plant.

The harvesting should not commence until the leaves begin to fall, and from green turn to yellow; this generally takes place in August. As they ripen, the heads should be removed singly, leaving a stalk from 10 to 30 centimetres (4 to 12 inches) in length; they are then removed to a shed or loft for five or six days till completely dry. The heads require careful handling in order not to damage the points of the "burrs." When perfectly dry, they are carefully sorted and packed in boxes or parcels containing 25 to 100 heads of uniform size and colour, and then stacked in a dry place.

The stalks of the plants are rooted up and dried to serve as fuel, especially for heating baking ovens.

The heads of teasel are usually sent away in bales or baskets of suitable size; for export they are packed in light wooden crates, weighing from 150 to 200 kilogs each (3 to 4 cwt.).

The average yield, in soils of medium quality, is at the rate of about 10 quintals of heads per hectare (8 cwt. per acre). In the Departments of Bouches-du-Rhône and Seine-et-Oise, where the land is more fertile, a production of about 15 quintals per hectare (12 cwt. per acre), is obtained.

The teasel is subject to the attacks of various insect and fungoid enemies. Amongst the former is a caterpillar, which preys on the leaves and stalks of the plant from April till July, devouring the heads just as they appear. For this pest there appears to be no remedy. Amongst the vegetable parasites are a fungus, the *panispera diapsis*, which also attacks other plants. For this, various chemical solutions have been used with some degree of success.

THE WHEAT HARVEST IN FRANCE.

The following estimate of this year's production of wheat in France has just been published by the Minister of Agriculture. The figures are based on the official returns from the ten regions or agricultural districts into which the country is divided.

This total production of 110,722,500 hectolitres (304,486,875 bushels), or 87,128,300 quintals (171,512,400 cwt.), works out at the average rate of 19½ bushels, or about 13¾ cwt. per acre for the whole of France.

As compared with the harvest of last year (1910), which amounted to 68,806,100 quintals (135,445,078 cwt.), that of the present year shows an increase of 18,322,200 quintals (36,067,322 cwt.).

Taking into account the 1½ million of foreign wheat in stock at the end of last month, and that remaining from last year's harvest, it is estimated that the quantity now existing in France will be sufficient to meet all the requirements of the population.

HOME INDUSTRIES.

Coal-miners and the Minimum Wage. — The meeting of the Conciliation Board for the federated mining districts in England and North Wales last week, to consider the question of a minimum wage, was not able to arrive at an agreement, but other meetings are to be held shortly, which, it is to be hoped, will settle this knotty problem. The owners' representatives on the English Conciliation Board had agreed to recommend a minimum wage to their districts, but it is doubtful whether the mass of the owners are as yet prepared to support them. It is not so much the abnormal place that is the difficulty with employers as the abnormal man. The demand of a section of the men is for a minimum wage for every coal-hewer, absolutely independent of any other circumstance than his descending the pit to do a day's work. The contention of the coal owners is that there are a large number of men employed who, by reason of age, physical unfitness, or lack of skill, produce regularly less than an average day's output of coal, and that if a minimum wage were fixed on the average wage of the district, then provision would have to be made for these workmen, or the employers would have to discharge all those whose output of coal fell below the average. This was the objection raised by the Lancashire coal owners at the joint meeting held in Manchester on November 8th. They offer to set up machinery to investigate every case where a workman fails to earn the average wage, and if this failure is proved to be due to faults in the coal seam, to hard coal or stone, or to any cause for which the management is responsible, they will pay the workman the average minimum wages of the district, but the owners object to the payment of the minimum wage when the failure to earn the average wage is due to some abnormality on the part of the workman. It is also pointed out that the concession of the extreme demand of the men would mean an entirely new method of payment for coal-hewers, instead of as now by contract, the wages depending upon the quantity of coal that the workman sends to the surface. It would mean the abandonment of the whole system of payment by results, and it is only by that system, as the owners contend, that they can regulate output without excessive supervision. Moreover, some colliers, to whom the piece-work system means high wages, are also against changing it. The offer now made by the owners may be defined as willingness to pay the average day's wage where there is proof of a fair day's work, and this surely should form a basis for a working arrangement between masters and men.

Manchester and Persian Trade.—Whatever may be the merits of the dispute between Russia and Persia, there can be no doubt as to the desire of Manchester that the territorial integrity of Persia shall be maintained. The present anarchical condition of affairs in Persia is very inimical to British trade, and if it were followed by partition of the country between England and Russia, things would go from bad to worse from the British trade point of view. The north-eastern provinces of Persia, which would go to Russia, are of enormously greater industrial value than the arid districts of the south, which would fall to England, and Russia with her rigid protection might be relied upon to put all possible barriers in the way of British trade. This is a view which, in the opinion of Manchester shipping houses, has not been sufficiently considered by the British Government.

Damp in Cotton.—Spinners have been trying for a long time to secure some amendment in the clause of raw cotton contracts referring to damp in cotton, and there has been another conference in Liverpool between representatives of the Federation of Master Cotton Spinners' Associations and the directors of the Liverpool Cotton Association. The spinners suggest that some test of a scientific character should be taken before arbitration proceedings begin, and that the arbitrator should take notice of such evidence. The directors of the Liverpool Cotton Association are considering the suggestion, and it is not unlikely that they will shortly consult their members upon the point.

Italy and Cotton Yarns.—According to Mr. Clive Bailey, British Consul at Warsaw, large quantities of cotton yarns are being imported into Poland from Italy to the detriment of the interests of local and British spinners. This importation is due not to any general extension of the foreign trade of Lodz, but to the depression of the cotton industry in Italy, where the warehouses are said to be full owing to over-production. The import of cotton yarns into Lodz is restricted to the higher counts, but the weaving industry of the neighbourhood does not appear to have benefited much by the opportunity of obtaining yarn at low prices.

The Insurance Bill.—The Insurance Bill having passed the House of Commons, it is not expected that it will be rejected by the House of Lords, so that in all probability it will be the law of the land and in operation as from July 1st, 1912. At a time when most men were speaking well of it, reasons were given in these Notes for questioning many of its provisions, and as a result of critical examination there are grave doubts as to its successful working. Many who are not extremists consider it a crude, unfair, and dangerous measure, but we must all hope that it will work better than many who would like to be its friends predict. However that may be, there is much in Sir Charles Macara's contention that the composition of Parliament has rendered it necessary that no great economic measure should be introduced without previous consultation with the most experienced men, representing both capital and labour, engaged in the great industries upon which our national existence depends.

Exports and Imports.—Whether Sir C. Macara is right in his view of the Insurance Bill must be

Hosted by Google

left to time to decide, but the Board of Trade returns just published afford abundant evidence, if that were needed, of the truth of his contention that the cotton industry is of enormous importance to the country. The increase in imports for the eleven months ended November 30th is over £6,300,000, and the increase in exports over £22,500,000, in comparison with the corresponding months of 1910. In the making of this record the cotton industry has had more than a proportionate share. The imports of raw cotton increased by nearly £6,000,000, and the exports of yarns and fabrics by £14,660,000, so that nearly the whole increase in imports and two-thirds of the increase in exports are due to the cotton industry. The growth in the value of the exports of cotton during the last three years has been remarkable. Taking for each year the eleven months ended November 30th, the figures are: 1909, £85,220,000; 1910, £96,023,000; 1911, £110,683,000.

Post Office Grievances.—The rumour that a postal strike will probably take place at Christmas is hardly likely to be verified by the event. The Postmaster-General has already intimated that the desired inquiry will be held in 1913, and a parliamentary paper has just been issued which shows how greatly the position of some of the post office men, in the matter of wages, has improved during the last quarter of a century. Comparing 1885 with 1910, the official figures show that the wages of male sorters have improved from 28*s.* 5*d.* to 50*s.* 7*d.*; of C.T.O. telegraphists (male), from 28*s.* 10*d.* to 50*s.* 10*d.*; of C.T.O. telegraphists (female), from 22*s.* 10*d.* to 29*s.* 8*d.*; of counter clerks and telegraphists (male), from 34*s.* 5*d.* to 49*s.*, and of counter clerks and telegraphists (female), from 21*s.* 11*d.* to 31*s.* 9*d.* These figures represent the average payment in each class, and go far beyond any rise in the cost of living. They are not, of course, an answer to the complaints of pensioners, temporary hands, and others, who say they are sweated; but they show at any rate that a good deal has been done to improve the position of Post Office employees in recent years.

The Shop Hours Bill.—The Shop Hours Bill has passed the House of Commons, but it has been much mauled in the passage. Under pressure of time, the Government has had to drop the main provision of the Bill, which limited the weekly hours that a shop assistant might work to sixty. This provision, which many considered the most important in the Bill, was debated in the Standing Committee, and was very generally supported, not only in the House, but in the country, but on the ground that it was contentious the Government dropped it. If it had been passed it would, allowing for the weekly half-holiday, have set up something like an eleven-hour day, and left the shopkeepers free to make with the assistants any arrangements which suited them and their customers. As it is, the assistants gain: (1) a weekly half-holiday; (2) three-quarters of an hour for dinner, or an hour if they have to go outside for it; (3) half-an-hour for tea; (4) a compulsory break after six hours' work. The Home Office is also to do what it can in the way of initiating and promoting early closing arrangements.

The Prudential Assurance Company.—The death of Sir Henry Harben, at the great age of eighty-eight, recalls the history of what is perhaps the most remarkable insurance business in the world. It was Mr. Henry Harben who in 1848 founded the Prudential in Ludgate Hill, near La Belle Sauvage Yard, with a capital of £2,500, and a staff of four. Now the head offices cover the whole of the site of Old Furnival's Inn, and the vast character of the business may be gathered from the fact that the total number of policies, ordinary and industrial, is over 19,000,000. The income of the Company for the year ended December last exceeded £16,500,000, and the capital funds are now more than £80,000,000, over £90,000,000 having been paid in claims. The management of the Industrial Branch of the business has of late been subjected to sharp criticism, but it will hardly be denied by the severest critics of its management that Sir Henry Harben, who for a long period was secretary of the Company, and afterwards and until his death its chairman, was a great administrator, who did a national service in popularising industrial and other insurance.

CORRESPONDENCE.

PRIORITY IN AEROPLANE THEORY.

Mr. O'Gorman condenses into a short note his views of the priority of Mr. Green in respect of certain results.

Now, questions of priority almost always lead to very prolonged and complicated discussions, and usually years pass, sometimes generations, before the supporters of the various claims cease to cap each other's references with references of still earlier date. With Mr. O'Gorman's permission, therefore, I shall not make myself responsible for either Monsieur Soreau's absolute priority or for the hard-and-fast date 1903. But though I do not definitely claim priority for Monsieur Soreau, I have no hesitation in denying it to Mr. Green. I presume Mr. O'Gorman's exposition at the meeting on December 1st to be the date of first publication of Mr. Green's results. That being so, I would refer him to Alexandre Sée's already classical memoirs collected in his book, "Les Lois Expérimentales de l'Aviation," published in Paris in the first quarter of 1911.

He will find that Figs. 87 to 99 deal very exhaustively with the graphical presentation of the familiar relations between weight, head resistance, inclination of supporting surfaces, velocity and engine power.*

* Eiffel ("La Résistance de l'Air et l'Aviation, Paris, 1910") gives an elegant variation of the graphical method in his polar diagrams, pp. 101–131.

He will note that these equations had been already presented by Soreau in his equally classical memoir, "État Actuel et Avenir de l'Aviation," read in January, 1908, to the Civil Engineers of France. No doubt he recollects that I presented the same equations at my lectures in the beginning of this year (February, 1911), and deduced the conditions for minimum power and minimum thrust, giving references to Soreau. (I might add that I obtained them independently in March, 1910, but mere independence of results rests on the word of the claimant, and the date of publication, or at least of communication to a recognised authority, is rightly held to be the criterion of priority.)

I would add that much of Sée's work is frankly adapted from Soreau. Mr. O'Gorman must also remember that results published in book form have usually appeared long before as scattered communications.

Writing away from a library, where reference is possible to the innumerable communications and memoirs scattered up and down the proceedings of the French Scientific and Technical Societies, I am unable to carry the discussion further. But let us remember that Pénaud established the classical condition for possible flight with given power, head resistance, reaction on planes, and weight (memoir published in 1872), in the 'seventies of last century.

He was followed by Renard, who completed his analysis, still in the nineteenth century.

Ferber began his gliding experiments in 1901, and carried the mathematical analysis still further. Finally, Soreau and Sée have completed the theory in the fullest detail. I mention only a few of the men whose work I am directly familiar with, leaving a host of names unmentioned.

This very sketchy note on the historical development of aeroplane theory has already taken up too much space. Others, no doubt, will fill up the many lacunae. But I cannot close without referring to the new ground taken up by Mr. O'Gorman in his letter. These equations, he states, have been applied to actual machines to predetermine their various characteristics. If he publishes his figures, he will make a real contribution to the practical development of British aviation, but will scarcely be able on that account to claim priority of method.

To conclude with some of my own experiments, let me state that I calculated similar characteristics for a Gnome-Bristol Biplane in October, 1910, that I determined 20° as the critical climbing angle, beyond which the machine "flops," and 16° as the utmost limit of correct flying on a calm day, and that I put these figures to a partial test by holding the machine at 12° inclination for a mile and a half, during which it climbed without any sensation of "flopping."

I often verified, by observation of pupils leaving the ground at too steep angles, that 16° to 20° was really in the neighbourhood of the point at which climbing gave way to "flopping." I have seen a pupil, unable to climb by pulling back the elevator, till his machine was inclined between 16° and 20° (a horrible sight), resolve to come down, push forward the elevator, and find himself soaring off like a bird at the smaller inclination.* The inclinations are referred to the horizontal axis of the machine.

Further, with a Vickers Rep Monoplane, tested at Brooklands in July 1911, we found from hard experience that there were two possible speeds (both theoretically stable, see Sée, Fig. 90). In practice, however, the lower speed had very poor stability laterally, and led to several bad landings soon after the get-off. Our pilots were accordingly instructed to get the machine's nose well down while running along the ground, and then to bring it up till the machine left the ground in the higher and more stable speed; otherwise there was risk of getting off the ground "cabré" in the lower speed with poor lateral stability. These two speeds are well known to Continental aeroplane flyers and designers equally with the poor lateral stability of the lower speed.

A. R. LOW.

DEW-PONDS.

One account I have read goes so far as to say that dew-ponds are so called because "they are believed to be fed by dew and vapours, *and not by rain*" (the italics are mine).

But surely no theory has ever been built upon so flimsy a foundation as this dew-pond theory:—*e.g.*, whenever Thomas Elliot, shepherd, "thought that a heavy dew or fog was to be expected, he notched a stick and drove it into the pond overnight, so that the notch was level with the surface. Next morning he pulled it up, marked how high the water had risen above the notch, and nicked it again for measurement." Mr. C. J. Cornish, who tells us this ("The Naturalist on the Thames," p. 129, 1902), calls the method a "simple and ingenious way." He does not tell us how the wetting of the stick by the fog or dew was allowed for, or what precautions were taken to ensure accurate reading. Under the circumstances the values given are modest. A gain of eight inches in depth of water on five winter nights is not too ambitious in point of quantity.

As for the idea, apparently much in favour with dew-pond theorists, that the "pans" in South Africa are dew-ponds constructed by aboriginal bushmen, one has only to see them to realise how absurd the suggestion is.

J. R. SUTTON.

Kimberley, South Africa.
November 17th, 1911.

---

* Painlevé gives some very interesting notes on the characteristics of an aeroplane, but exaggerates the "acrobatism" necessary to maintain the lower speed. He deduces from purely theoretical considerations the paradox mentioned in this communication—that to climb, the pilot flying in the second speed must reverse the ordinary rules for control, *i.e.*, he must push forward the lever, depress the nose of the machine, decreasing his inclination and increasing his climbing powers. See *Technique Aéronautique*, January 1st, 1910.

GENERAL NOTES.

Coach-building Prizes.—The Worshipful Company of Coach Makers and Coach-harness Makers of London offer the following prizes for competition among British subjects engaged in coach and coach-harness making and motor-body making, and members of drawing and technical classes in connection with such trades, resident in the United Kingdom of Great Britain and Ireland:—Competition No. 1 (open to all)—The Master, Mr. Frank Lindsay Sutton, offers £10 10*s*., and the Company £5 5*s*. and their silver and bronze medals, for a set of five working drawings of a Motor Caravan—side view—view of the interior (taken from back to front)—plan—front view—and rear view; all to the scale of 3 inches to the foot, and accompanied by detail drawings of the internal fittings so far as may be necessary to explain them. The caravan body divided into a small kitchen and a room in which four men can sleep, and which may be used as a sitting-room, with table, seats, etc. A tank to hold twenty gallons of water and a wash-hand stand and lockers for bedding, clothes, and some provisions, to be provided. The body suitable for a chassis with a wheel base 12 feet long, and 4 feet 4 inches wide from centre to centre of tyres. The body may overhang the chassis; in pencil, on paper 10 feet 6 inches by 5 feet 6 inches. Original improvements will receive special consideration. 1st prize, the Company's silver medal and £10 10*s*.; 2nd prize, the Company's bronze medal and £5 5*s*. Competition No. 2 (open to all)—For a set of four scale drawings—*i.e.*, off-side (showing levers, pedals and steering-wheel), sectional, half-rear and half-plan views—of a Limousine motor carriage-body with completely enclosed front and to seat six persons. No interior upholstery to be shown; the sectional drawing to be a perpendicular section taken lengthways through the middle of the body from front to back; designed for any known type of motor chassis of not more than 10 feet 6 inches wheel base; the wheels to be indicated by circles; details of chassis other than specified not required; scale, 1½ inches to the foot; in ink, on paper 48 inches by 36 inches. Original improvements will receive special consideration. 1st prize, the Company's bronze medal and £5 5*s*.; 2nd prize, £3 3*s*. Competition No. 3 (open to journeymen harness-makers)—For a black harness crupper for a 16-hand horse, brass furniture, buckle dock and small loops; to be the work of one man. It is suggested that harness-making firms assist by allowing competitors to effect the work where employed. 1st prize, the Company's bronze medal and £3 3*s*.; 2nd prize, £2 2*s*. Competition No. 4 (open to all)—For a sheet of drawings—on paper 48 inches by 36 inches—showing not more than six, and not less than three designs—to any scale—illustrating convenient methods for disposing of all the following accessories, viz.: Spare wheel with tyre complete, extra cover, two inner tubes, jack, pump, tools, accumulator, generator, fire extinguisher, tin of petrol, passengers' and driver's luggage (occupying a minimum space of 5 cubic feet), and luncheon basket, fitted to an open car for four persons, mounted on a chassis of 8 feet 6 inches body space; the spaces under the front and rear seats are not to be available. Only such parts of the body as are necessary need be drawn. Each drawing may be accompanied by a short explanatory description. Original improvements will receive special consideration. 1st prize, £5 5*s*.; 2nd prize, £3 3*s*.; 3rd prize, £1 1*s*. Competition No. 5 (open to youths under twenty-one years)—For a side view and half plan of a cab-shaped Victoria, without upholstery or leather work, suitable for one horse; scale, 1½ inches to the foot; in pencil, on paper 27 inches by 18 inches. 1st prize, £3 3*s*.; 2nd prize, £1 1*s*. Each of the prizes will be accompanied by the certificate of the Company.

Exhibition of Autocars and Aerial Navigation, Paris, 1912. — A commission has been appointed by the French Government for the purpose of organising an exhibition of Motor-cars and Aerial Navigation in Paris next year. The exhibition, which has the support of some of the most important firms in the trade, will probably be held in the Grand-Palais.

British Silk Exhibition, 1912.—Under the auspices of the Silk Association of Great Britain and Ireland, an exhibition will be held from June 5th–19th, 1912, at Prince's Skating Club, Knightsbridge, S.W., with the object of bringing before the public the great advance that has been made in the production of home-made silk fabrics. A special committee has been formed to deal exclusively with the financial and other arrangements for the exhibition, and an ample guarantee fund has been subscribed.

Oil Mills in Palestine.—Although the old-style olive mills are fast being replaced by the modern French machines, serig or sesame-seed oil is made in the district of Jerusalem by the old and primitive methods, except in one mill. The seeds are first soaked in water and then shelled by pounding in a large stone mortar with a huge wooden mallet. They are next roasted in an oven and then ground in a stone mill turned by a camel, the result being a thin greyish paste. This is then poured into a circular vat with a concave bottom. When the vat is full, the fluid being about three feet deep, a man gets into the vat and treads the paste with his bare feet, which brings the oil-cake to the bottom, and as the oil comes to the top it is skimmed off with a brass bowl. A German at Sarona has lately begun the manufacture of this oil with a European machine, the seeds not being roasted but simply crushed and pressed. The resulting oil is much lighter in colour and commands a better price, but it is stated that by this process less oil is obtained from the same amount of seed than by the native method.

Scientific Fish Culture in Uruguay.—A work of considerable magnitude and interest is to be initiated by the new Uruguayan Minister of Industries, viz., fostering the fishing industry. He proposes to secure the services of a foreign expert in fish culture, and to establish a fisheries institute with a permanent fishing station on the east coast of Uruguay. According to the United States Consul at Montevideo, one of the professors of the agricultural college at Sayago, an authority on pisciculture, has been engaged for some time in a study of the sea and fresh-water fishes of the Republic. When his report is presented a bill will be prepared dealing with the question. The sea and rivers of Uruguay teem with edible fish, but as yet no attempt has been made to organise the fishing industry on a scientific basis, nor have any measures been adopted to protect the fish from extermination.

MEETINGS OF THE SOCIETY.

Cantor Lectures.

Monday evening, at 8 o'clock:—

Professor Vivian B. Lewes, "The Carbonisation of Coal." Four Lectures.

Syllabus.

Lecture IV. — December 18. — *The Possible Improvements in Carbonisation.*—The aims of the gas manager and coke producer—Experiments on low temperature distillation and their teaching—The rivalry existing between fully-charged retorts, vertical retorts, recovery ovens, and chamber carbonisation — The intermittent vertical retort *versus* the continuous vertical systems—The Settle-Padfield, Duckham-Woodall, and Glover-West processes—The ideals of carbonisation—The volume of gas due to primary and secondary reactions—The gasification of tar—The limitations of volume and quality of gas—The ends to keep in view in devising new processes of carbonisation.

MEETINGS FOR THE ENSUING WEEK.

Monday, December 18...Royal Society of Arts, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Professor Vivian B. Lewes, "The Carbonisation of Coal. Lecture IV.—The Possible Improvements in Carbonisation."

Bibliographical, 20, Hanover-square, W., 5 p.m. Mr. F. Madan, "The Duplicity of Duplicates, with a Note on a New Bibliography."

British Academy, in the Theatre, Burlington-gardens, W., 5 p.m. (Schweich Lectures.) Professor R. A. Stewart Macalister, "The Philistines, their History and Civilisation." (Lecture II.)

Geographical, Burlington-gardens, W., 8.30 p.m. Dr. T. McDougal, "American Deserts."

British Architects, 9, Conduit-street, W., 8 p.m. The Practice Standing Committee on "The Newer Responsibilities of Architects."

Actuaries, Staples Inn Hall, Holborn, W.C., 5 p.m. Mr. W. Palin Elderton, "Some Recent Statistical Results."

East India Association, Caxton Hall, Westminster, S.W., 4.30 p.m. Mr. J. C. White, "A Short Description of Sikhim, Lhasa, and part of Tibet."

Tuesday, December 19...Statistical, at the Royal Society of Arts, John-street, Adelphi, W.C., 5 p.m. Mr. E. Crammond, "The Economic Position of Scotland and her Financial Relations with England and Ireland."

Illuminating Engineering Society, at the Royal Society of Arts, John-street, Adelphi, W.C., 8 p.m. Mr. H. T. Harrison, "Some Aspects of Railway Station and Goods Yard Illumination."

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Discussion on paper by Dr. T. E. Stanton and Mr. J. R. Pannell, "Experiments on the Strength and Fatigue Properties of Welded Joints in Iron and Steel."

Colonial, Whitehall Rooms, Whitehall-place, S.W., 4 p.m. Sir George Scott, "Burma the Cinderella."

Wednesday, December 20...Meteorological, 25, Great George-street, S.W., 7.30 p.m. 1. Mr. W. Larden, "Solar Halos and Brocken Spectres." 2. Mr. W. H. Dines, "The Statical Changes of Pressure and Temperature in a Column of Air that accompany Changes of Pressure at the Bottom."

Geological, Burlington House, W., 8 p.m.

Microscopical, 20, Hanover-square, W., 8 p.m. 1. Mr. F. Shillington Scales, "Photomicrography of the Electrical Reactions of the Heart." 2. Rev. H. Friend, "British Tubificidæ."

Thursday, December 21...Linnean, Burlington House, W., 8 p.m. 1. Rev. H. Friend, "Some Annelids of the Thames Valley." 2. Mr. R. C. Compton, "The Seedling Structure of Leguminosæ." 3. Professor P. Groom, "The Internodes of *Calamites*." 4. Mr. W. C. Worsdell, "Some Abnormal Toadstools and their Morphology." 5. Dr. A. B. Rendle, "Dissected Leaf-form of Horse-radish."

Chemical, Burlington House, W., 8.30 p.m. 1. Messrs. R. H. Pickard and J. Kenyon, "Investigations on the Dependence of Rotatory Power on Chemical Constitution. Part II.—The Rotations of Some Secondary Alcohols containing the Iso-propyl Group." 2. Messrs. R. H. Pickard and W. O. Littlebury, "The Alcohols of the Hydroaromatic and Terpene Series. Part II.—The Menthols corresponding to Optically Inactive Menthone." 3. Messrs. J. J. Dobbie and J. J. Fox, "The Absorption Spectra of Quinine, Cupreine, 6-methoxy-quinoline and 6-hydroxy-quinoline."

Mining and Metallurgy, at the Geological Society, Burlington House, W., 8 p.m. 1. Mr. C. Olden, "Emeralds: Their Mode of Occurrence and Methods of Mining and Extraction in Colombia." 2. Mr. W. C. Walworth Pearce, "The 'Glen' Bismuth Mines, North Queensland." 3. Mr. F. A. Killik, "Notes on a Simple Method of Separating Rock from Stiff Clays." 4. Mr. H. R. Sleeman. "The Whim Well Copper Mine, West Pilbara, North-west Australia."

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Mr. H. W. Fincham, "A Ramble in Old Clerkenwell."

Historical, 7, South-square, Gray's Inn, W.C., 5 p.m. Professor A. Szelagowski and Mr. N. S. B. Gras, "The Eastland Company in Prussia."

Numismatic, 22, Albemarle-street, W., 6.30 p.m. Sir Arthur J. Evans, "The Artistic Engraver of the Terina Mint and the Signature of Evaenetos on his late Didrachm Dies."

Correction.—In a note on page 80 of the last number of the *Journal*, it is stated that the date of William Kay's birth is given in Lord's Memoir as 1765. This is a mistake. The William Kay born in 1765 was the grandson, not the son, of John Kay. The date of the birth of William Kay the elder is given, no doubt correctly, by Lord as July 14th, 1745.

Hosted by Google

Journal of the Royal Society of Arts.

No. 3,083. VOL. LX.

FRIDAY, DECEMBER 22, 1911.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

CANTOR LECTURES.

On Monday evening, December 18th, Professor VIVIAN B. LEWES delivered the fourth and final lecture of his course on "The Carbonisation of Coal."

On the motion of the CHAIRMAN a vote of thanks was accorded to Professor LEWES for his interesting course.

JUVENILE LECTURES.

The usual short course of lectures adapted for a juvenile audience will be delivered on Wednesday afternoons, January 3rd and 10th, at 5 o'clock, by CHARLES VERNON BOYS, F.R.S., on "Soap Bubbles."

Each Member is entitled to a ticket admitting two children and an adult.

A sufficient number of tickets to fill the room will be issued to Members in the order in which applications are received.

Members who require tickets for the course are requested to apply for them at once.

Syllabus.

LECTURE I.—JANUARY 3.—The surface actions of water and other liquids—Peculiar properties of solutions of soap and of saponine with which bubbles may be blown—The strength of bubbles—Soap films on frames—Froth—Composite bubbles.

LECTURE II.—JANUARY 10.—Out-of-door bubbles—Floating bubbles—Soap bubbles as an aid to experiment—Experiments with soap bubbles—The colours of soap bubbles—Permanent celluloid films showing the colours of soap bubbles.

The lectures will be illustrated by numerous experiments.

LIST OF MEMBERS.

The new edition of the List of Members of the Society is now ready, and can be obtained by Members on application to the Secretary.

COVERS FOR JOURNALS.

For the convenience of Members wishing to bind their volumes of the *Journal*, cloth covers will be supplied, post free, for 1*s.* 6*d.* each, on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

THE CARBONISATION OF COAL.

By VIVIAN B. LEWES,

Professor of Chemistry, Royal Naval College, Greenwich.

Lecture I.—Delivered November 27th, 1911.

THE COMPOSITION OF COAL.

The carbonisation or destructive distillation of coal is carried out with the object of obtaining the latent energy which it contains in such a form that when liberated it can be most easily applied to our special needs, and as coal consists of a complex mixture of carbon with compounds of carbon, hydrogen, and oxygen, which can be broken up by the action of heat into solid, gaseous, and liquid products, processes of destructive distillation have arisen in which, by varying the temperature and methods of carbonisation, it has been possible to obtain the best results either in the gaseous or solid products, according to whether the operation has been carried out at the gasworks with the object of making illuminating gas, or in the coke oven in order to make metallurgical coke.

Before it is possible to explain the highly complex actions taking place in the destructive distillation of coal, it is important to have some definite idea of the nature of the raw material with which we have to deal, and although many attempts have been made to gain an insight into the composition of coal, the wide variations in its characteristics, the difficulties attending any attempt to separate its constituents, and the

Hosted by Google

ease with which the products of its decomposition undergo secondary changes at the temperatures employed in breaking it up have prevented any very satisfactory solution of the problem being arrived at.

The one thing generally admitted is that coal is the fossil remains of a vegetation that flourished in the carboniferous period of the world's history, and that it has passed through successive stages of checked decay, the action of time, temperature, and pressure, generally out of contact with air, resulting in the conversion of these remains into the tertiary coals, such as brown coals or lignites, and probably by a continuance of the action yielding eventually the true coal.

In a previous course of Cantor Lectures I went into that wonderful cycle which, in Nature, purifies the atmosphere by utilising the waste products of life and decay—water vapour and carbon dioxide—as the food on which the vegetable kingdom is reared, and showed that, under the influence of the sun's rays, the growing plant built up its tissue from the carbon, hydrogen, and oxygen of these bodies, at the same time rendering latent and storing the solar energy in the compounds formed, and that these, converted by time, temperature, and pressure into coal, after countless ages yield back on combustion the heat that was derived from the prehistoric sun.

So far all authorities are agreed, but the changes which take place in the conversion of the plant material into the coal, and the nature of the compounds present in the various kinds of coal, which give this body its widely diverging characteristics, still remain unsolved in spite of the century of work which has been expended on the question, and the fact that it has been attacked from almost every point of view.

The chemical theories that have been brought forward nearly all start with the assumption that the original material from which the coal has been formed is $n(C_6H_{10}O_5)$, an empirical formula which represents the class of bodies known as "celluloses," and in which the ratios of the atoms lend themselves to an easy explanation of the formation of various kinds of coal by the subtraction of various proportions of the known gaseous products of the checked decay taking place in the formation of peat, lignite, and coal—*i.e.*, methane, CH_4, carbon dioxide, CO_2, and also water, H_2O.

Some theorists have held that the infiltration of water holding oxygen in solution was responsible for actions which, leading to the evolution of these compounds, have resulted in the concentration of the carbon; others have looked upon the action as one of dehydration, and both are probably right to the extent that the conditions under which coal has been formed are so various that cases could be found to support either theory.

Moreover, such theories are rendered invalid by the fundamental errors of supposing that Nature is dealing with purified cellulose, and that the various coals are definite compounds that can be represented empirically by a formula.

Our only knowledge of the coal plants is derived from their fossilised remains, and owing to the complete nature of the destruction that has taken place in structure, the evidence to be obtained is small indeed; but although of a totally different and far more simple form, it must be that the plant life of the carboniferous period which gave rise to our coal deposits varied as much in character as does the sphagnum of a peat bog from the timber of a forest.

Although the vegetable fibres of all forms produced by plant life contain cellulose, they also contain ligno-cellulose and other allied compounds, whilst they vary in the extractive matter of their sap to a very great extent, so that even supposing they all underwent the same treatment as regards time, temperature, and pressure during their conversion into coal, we should expect wide differences in composition in the coal formed, whilst as the conditions vary even more than the material dealt with, it is small wonder that great differences are found between the coals from every seam in a colliery, and even between different parts of the same seam.

Impossible as it is to give accurate explanations of changes such as those taking place under conditions of which we know only the general trend, and in material the composition of which is of the most variable character, we are met by the further difficulty that when we have the coal itself, its refractory behaviour towards solvents and any ordinary reagents prevents our learning much more about its constitution than can be given by an ultimate analysis giving its percentage composition, or a proximate analysis showing the effect upon it of heat in causing it to yield fixed carbon, volatile matter, ash, and moisture.

It is quite clear that in our present state of knowledge all that is possible is a generalisation based upon the known facts, the truth or otherwise of the theory being shown by how far it is in accord with the observations made in

Hosted by Google

practice upon the results yielded by destructive distillation.

Twenty years ago I came to the conclusion that the most satisfactory view to take of the composition of coal was that it consisted of an agglomerate of the solid degradation products of vegetable decay, together with such of the original bodies as had resisted to a greater extent the actions to which it had been subjected, and all the experience of wood, peat, and coal carbonisation which I have had since confirms me in the opinion that this is in the main correct.

All the plants of which we have fossilised record in our coal measures consisted of sedges and reeds, tree ferns, club mosses or lycopodia, and trees akin to the pine; but in those prehistoric days the conditions of growth—warmth, moisture, and carbon dioxide—were such that these plants grew with a succulent freedom and rapidity unknown in latter days, and this rendered their tissue an easy prey to decay and fermentation, actions which left only the more resistant unchanged. The work of Morris, Carruthers, Fleming, and Huxley has shown us that the bituminous matter in coal is largely derived from the spores of fossil mosses akin to the lycopodia.

If we take the club mosses of to-day, we find that their spores give us that body known as lycopodium, a substance so resinous in its nature that it resists the action of water, and is used to coat pills, whilst the same resinous characteristics render it so inflammable that a little blown through a flame provides the theatrical world with its artificial lightning. Spores of this character from the giant growths of the carboniferous period, together with the more resinous portion of plants akin to the pine, are the substances which have resisted the actions taking place during the ages that have elapsed in the formation of coal.

Our knowledge of the constituents entering into the multitude of changes taking place in the formation of coal is restricted to carbon, hydrogen, and oxygen; but it is improbable that the mineral constituents of the sap and fibre of the original vegetation play any important part in the actions that lead to the change, as although the reduction of sulphates to sulphides, and the combination of the sulphur with iron from the surrounding soil to form pyrites and organic compounds containing sulphur, and the deposition in the mass of other water-carried salts, all tend to the production of the ash of the coal, they do not affect the carbonaceous material in its main changes.

In the same way nitrogen compounds, which are found in every fuel of vegetable origin, are present in all stages of the formation from peat to coal, but it is impossible to suppose that they play any part in the change, whilst water, although it is probably an active factor and also a product in the decompositions, cannot be taken into account in considering the actual course of the changes from analyses of the body produced. Hence, in tracing the probable course of the degradation of the vegetable matter through its various stages, it is better to ignore all such factors and deal only with the variations of the carbon, hydrogen, and oxygen in the material.

Starting with the fibre of the original plants, we find two well-defined bodies—cellulose, as represented by cotton fibre, and lignose, as represented by jute fibre; in the former the percentage of carbon is 44, in the latter 47, each giving distinctive reactions with dilute acids at 70° C., with anilin sulphate, with Schultze solution, and with mixtures of sulphuric and nitric acids. In the cellular tissue we find starch, and besides these bodies there are present the extractive and mineral matters of the sap.

Amongst the extractive matter we find gums, such as those exuding from the acacia and cherry, but also present in the juice of many plants, mucilage, vegetable jelly, which gives many juices their power of gelatinising, resins, essential oils, and other well-defined bodies. With some forms of vegetation the essential oils undergo oxidation and form resins, and these, being more resistant to change, accumulate in masses of decaying vegetable matter, so that large quantities of them are found in lignite beds in a fossilised but little changed state.

The changes in the carbohydrates and extractive matters depend largely upon the conditions of decay. Given moisture and air, they become converted into carbon dioxide and water; check the decay by cutting off free access of air, the action is slowed down, and the gases evolved are carbon dioxide and methane.

It is clear that in a mass of rotting vegetation undergoing checked decay, fermentation must play an important part, and Renault* found, in an extensive series of researches upon peat, that the most important factor in the conversion of vegetable deposits into peat were fungi and

* *Bulletin de la Société de l'Industrie Minérale*, 3 Sér., XIII. 865.

bacterial ferments, which give rise to the production of ulmic compounds of the composition:—

Carbon	65·31
Hydrogen	3·85
Oxygen	30·84

Mulder* also at an earlier period found that bodies could be extracted from peat, to which he gave the name of humic and ulmic acids, and Einof, Proust, and Braconnot found that such bodies form the chief portion of peat:—

	Carbon.	Hydrogen.	Oxygen.	Nitrogen.
Humic acid	60·13	4·74	31·52	3·61
Ulmic acid	62·03	4·65	33·33	—

Whilst Herz† found bodies of the same character in lignites, which he called carbo-humic and carbo-ulmic acids, of the composition:—

	Carbon.	Hydrogen.	Oxygen.
Carbo-humic acid	64·59	5·15	30·26
Carbo-ulmic acid	62·36	4·77	32·87

Fremy‡ also found that not only lignites, but bituminous coals could be dissolved in a mixture of mono-hydrated sulphuric acid and nitric acid, giving a dark brown solution, from which an ulmic compound is entirely precipitated by water; whilst Anderson§ has shown that by similar treatment bodies of the same character can be obtained from both caking and non-caking coals.

None of these bodies are probably definite compounds, and resemble the residues obtained by the action of dilute acids on sugar and starch.

The evidence, however, seems to point to the presence in all bituminous forms of coal as degradation products of the original vegetation of a humus or ulmic character, which is probably the portion carrying the nitrogen, and in round numbers the proportions of the carbon, hydrogen, and oxygen will be not far removed from:—

Carbon	63 per cent.
Hydrogen	5 ,,
Oxygen	32 ,,

It is also well known that the tertiary coals, like the brown coal and lignite deposits, are rich in fossil gums and resins, derived from the extractive matter of the vegetation, and a number of these have been isolated and analysed, whilst Mulder has found resinous bodies of a similar character in the Friesland peat. (See table below.)

It will be noticed that the products from the lignite differ but little from Mulder's peat resins, whilst it is interesting to note that in the lignite beds of Saxony layers of opaque yellowish brown matter are found (the pyropissite of Kenngott), which yields up to 62 per cent. of paraffin on distillation, and is the body from which Wackenroder and Bruckner extracted their resins.

It is evident that in coal there are resin bodies of this character approximating to the general composition:—

Carbon	79 per cent.
Hydrogen	11 ,,
Oxygen	10 ,,

The amount of resin constituents in the original vegetation, which concentrates itself in the coal, must play an important part in chemical changes taking place during the formation and ultimate composition of the coal; and it is clear that although the vegetation that flourished in the coal age was of a very different character from that of later periods, yet in all probability the variations in the extractive

matters of the plants varied to much the same extent as in the flora of to-day, so that some deposits would be formed from vegetation containing but little of the resin-forming constituents, whilst other deposits would be rich in them. We know the wide differences there are in the physical characteristics of the lignites, sometimes more like wood than coal, at others black, shining, and with a conchoidal fracture, these variations in appearance being due to the conditions under which they have been formed and the amount of the resin constituents present.

If we start with the humus and resin constituents as they exist in the peat deposits of to-day, the latter are present only to the extent of 5 to 10 per cent., but in the decaying vegetation of the carboniferous age were probably present in much larger quantities, and the humus, unprotected by it, rapidly undergoes decomposition with concentration of carbon and evolution of methane, carbon dioxide, and water. As the layers of deposit above the carbonising mass grow thicker, so probably the temperature rises, and the ratio of resin constituents increasing in proportion binds together the mass, and so helps to protect the remaining humus, and with the lapse of centuries lignite is formed.

If the amount of resin constituents has been small or, owing to local circumstances, has not been distributed evenly throughout the mass, the lignite is loose in structure, and during the ensuing ages continues decomposing until, if the pressure has been great and the temperature high, nothing but the residual basis and trace of resin constituent are left in the form of steam-coal or anthracite, whilst under other conditions they may remain mixed with the bituminous coal in a seam and form the "Mother of Coal."

If the percentage of resin bodies has been very high, as in a drifted deposit of spores from lycopodia, and the temperature has been high, the resin bodies may become semi-liquid, and mingling with surrounding earthy deposits, will give such compounds as the Boghead cannel, the organic matter in which has the same composition as resin, whilst it yields 33 per cent. of ash. Some of the cannels, however, are simply very rich bituminous coals.

When the temperature has been high enough some of the resin constituents have practically distilled into the underlying clay, yielding some forms of shale.

Heat also may cause isomeric and other changes in the resin bodies, thus altering their behaviour towards solvents, whilst the effect of heat under pressure upon the resins is in some cases to decompose them with formation of hydrocarbons, a long series of which were isolated by Renard, amongst them being both saturated and unsaturated groups, together with hydrocarbons containing oxygen. Hydrocarbons like retene, $C_{18}H_{18}$, have frequently been isolated, and this body is found in many lignites, whilst within the last few months Pictet and Ramseyer have isolated hexahydrofluorene, $C_{13}H_{16}$, and others of the hydroaromatic hydrocarbons from coal, bodies which are resolved into aromatic hydrocarbons and hydrogen during destructive distillation. Renard long ago isolated not only saturated hydrocarbons like pentane and hexane, but also hexahydrides or naphthenes, isomeric with the ethylene series, from the resin-oil obtained by distilling wood resin at a low temperature (350° C.), amongst these hexahydrides being C_7H_{14}, C_9H_{18}, and $C_{10}H_{20}$, and the presence of bodies of this character in low temperature coal tar is a further proof of the presence of the resin bodies in coal.

All these degradation products of the original vegetation are to be found in the bituminous coals, the residual body and humus forming the basis, which is luted together by the hydrocarbons and resins, and the characteristics of the various kinds of coal are dependent upon the proportions in which the four groups of the conglomerate are present.

These constituents of the coal have their own characteristic products of decomposition when the coal is subjected to carbonisation.

The humus bodies during carbonisation yield a large proportion of the gaseous products, and under the influence of heat show no sign of melting, but begin to break up at about 300° C., the decomposition becoming more rapid as the temperature rises. Water distils over in the early stages, the tar is thin and poor in quantity, and the gases up to 600° C. consist of hydrogen, methane, and carbon dioxide, with smaller quantities of carbon monoxide and traces of other saturated hydrocarbons; the decomposition can be completed below 600° C., but if the temperature is run up to 1000° C., the carbon dioxide is reduced in quantity by the action on it of the red-hot carbon, and carbon monoxide increases correspondingly, whilst hydrogen and methane are still evolved.

The decomposition of the humus is also largely affected by the rate of heating; if slowly heated, a large proportion of the oxygen is given off in combination with hydrogen as water vapour, whilst, if quickly raised in temperature, more

Hosted by Google

combines with carbon to form carbon dioxide and monoxide.

The residue shows no sign of caking, whilst, like the naturally-formed residue—mother of coal—it requires a large proportion of cementing material to make the particles cohere.

The resin bodies and hydrocarbons which form the cementing portion in the coal melt between 300° C. and 320° C., and if a coarsely-powdered sample of the coal becomes pasty or semi-fluid at this temperature, it is a strong inference that the coal will coke on carbonisation, a fact noted by Anderson, and which I have found very useful in practice as a rough test. About these temperatures also the resin bodies and hydrocarbons begin to decompose.

The resin bodies at low temperature yield saturated hydrocarbons, unsaturated, chiefly hexahydrides or naphthenes, together with some oxygenated compounds, whilst the hydrocarbons yield paraffins and liquid products, all these primary constituents undergoing further decomposition at slightly higher temperatures. The liquids so produced begin to distil out as tar vapours and hydrocarbon gases, and leave behind with the residuum pitch, which at 500° C. forms a mass already well coked together if the residuum from the humus is not too large in quantity. The coke formed at this temperature is, however, soft, but if the heat be now raised to 1000° C., the pitch residue undergoes further decomposition, yielding gas and leaving carbon, which binds the mass into a hard coke.

It has been shown by Muck and other observers that it is not always the coal containing the largest amount of volatile matter that evolves gas most rapidly or is richest in hydrocarbons, and this naturally follows from the fact that those coals which have the highest oxygen percentage are mostly those giving high volatile matter, and as these are rich in the humus bodies which yield most of the diluting gas and but little tar or rich hydrocarbon gases, they cannot give the high result of a coal in which the oxygen content is about 10 per cent. or rather lower, and which contains a large percentage of resin bodies.

Observers have differed as to the nature of the binding material in coke, some holding that it is the residuum of the semi-fused constituents of coal, whilst others, chief amongst whom was Wedding, consider that it is carbon shed off by the decomposition of heavy hydrocarbon vapours, which is undoubtedly the cause of the carbon hairs found in coking. My own opinion is that the cementing material is due to liquid products, the most volatile of which go off as vapours leaving pitch, which carbonises and binds the mass into coke, and in considering the actions taking place during carbonisation ample proof of this will be adduced.

It is clear that the binding material is formed below 450° C., as if we take a good coking coal and carbonise it at 450° C., we obtain coke which, although not strong, is perfectly luted together; but if we now powder this low temperature coke and again carbonise it, a large yield of poor gas is evolved, but no coking of the residue takes place.

There is no doubt in my mind that it is the resin bodies and their derivatives the hydrocarbons in the coal that form the tar, which yields the pitch which lutes the coke, and also that the resin bodies play a very important if not the chief part in the weathering of coal.

Experience shows that the weathering of coal is a phenomenon which is dependent upon the absorption of oxygen from the air, and this weathering is fatal to the coking of some coals, the slacks of which are so susceptible to oxidation that a few days' or weeks' exposure destroys their coking power.

Now, the avidity of oxygen for some vegetable resins is well known—the rapidity with which copal will absorb oxygen from the air may be taken as an example, and common resin has itself been formed by the oxidation of turpentine, and countless ages under conditions tending to reduction may well have whetted anew the resinic appetite for oxygen.

In any case, the resin bodies are the compounds present in the coal most likely to possess this property, and it is the chemical actions so caused which lead to slow combustion, and, when accelerated by any rising in the surrounding temperature, are capable of generating sufficient heat to lead to the spontaneous ignition of masses of broken coal large enough to prevent the escape of the heat as it is developed.

Coal exhibits to a lesser extent the same property of absorbing gases that charcoal does, and the least absorbent will take up one and a quarter times its own volume of oxygen, whilst many bituminous coals will absorb more than three times their volume of the gas; and this action, at first largely physical, presents the oxygen in a probably active condition to the resin bodies in the coal, and leads to the rapid "weathering" and destruction of the coking properties found with some kinds of coal.

Boudouard * has shown that when coal is

* *Compt. Rend.*, 1909, 148, 284-286.

Hosted by Google

weathered, humus bodies are produced, and the coking power lessened or destroyed. In seven samples of various coals the humus constituents were increased by the oxidation, which seems to show that the action of the absorbed oxygen is to attack the resin compounds, and as we know that carbon dioxide and moisture are the chief products of the earlier stages of heating of masses of coal, it seems probable that the result is a conversion of resinic into humus bodies with evolution of these gases, and it is this change which leads to the serious deterioration in the gas and tar made from coal which has been too long in store, whilst the fact that cannel coals like Boghead or a shale do not weather is partly due to their dense structure, and also is an indication that the resin bodies of which they are chiefly composed are of a different type—a fact borne out by their resistance to certain coal solvents which freely attack the ordinary resin matter.

The lines of research intended to throw light on the composition of coal have been either to distil the coal at various temperatures and to draw inferences from the products of the nature of the original substance, or to attack the coal directly by means of solvents.

The early attempts to isolate definite bodies from coal by solvents were none of them very successful, ether, alcohol, petroleum ether and benzol proving to have but little solvent action, whilst Guignet succeeded in extracting by the use of phenol a small quantity of a brown amorphous body from a bituminous coal, but did not identify it. In 1894 Professor Bedson reported to the British Association the results of a long series of experiments, in which, besides these solvents, he also tried acetic anhydride, glacial acetic acid, turpentine and anilin, the last solvent proving the most successful, extracting from the coal a body of the same character as that obtained by Guignet, which, when treated with benzene and with ether yielded on evaporation bodies of a resinous character. He also found that when finely-divided coal is suspended in boiling water and permanganate added, oxidation of some constituents of the coal ensues, and a dark brown alkaline liquid is formed.

In a further report in 1896 he gave the results of acting upon coal with hydrochloric acid and potassium chlorate, and showed that chlorinated compounds are formed of the same character as those obtained by Cross and Bevan from jute fibre.

Bedson made a great advance in this line of research when in 1899* he pointed out the solvent power of pyridine bases extracted from coal tar, which dissolved 16 to 18 per cent. of a Durham coal, but had no action on anthracite.

In 1901 Baker † experimented upon the action of this solvent on several coals, and found that from Durham coal (Hutton seam) 20·4 per cent. could be extracted from pyridine, and that after extraction the residue had lost the coking properties of the original coal.

This observation was confirmed, in 1902, by Anderson and Henderson ‡ who tried the action of pyridine in a research upon the coals of Bengal and Japan, and also upon some Scotch coals, the coking powers of which were known, and they found that the extraction of a strongly coking coal by pyridine weakened the coke, whilst with inferior coking coal the property is entirely destroyed.

In 1908 Professor Bedson § read a paper before the Society of Chemical Industry, in which he gave the results of experiments upon six coals obtained from the Redhaugh Gasworks, which seem to show that with some gas coals an amount equal to practically the whole of the volatile matter capable of being driven off by heat can be extracted by pyridine:—

	Volatile matter per cent.	Pyridine extract per cent.	Gasworks yield per ton.	Candle-power.
I. . . .	34·10	32·36	11,381	16·63
II. . . .	33·28	35·59	11,392	16·50
III. . . .	31·91	24·58	11,646	16·40
IV. . . .	31·7	22·81	11,108	16·00
V. . . .	33·65	29·97	10,913	16·39
VI. . . .	30·87	22·53	10,730	15·76

Now, from these figures the inference is that in a coal like II. everything beside the fixed carbon and ash has been dissolved—that is, the humus, resin, and hydrocarbon bodies, and it would have been of the greatest interest had Professor Bedson made an analysis of the residue, or at any rate shown that no volatile matter was left in it.

I have never had the good fortune to obtain a coal from which the pyridine extracted a percentage equal to the volatile matter as given by analysis, even after much longer periods than those utilised by Professor Bedson, but such a coal offers a most valuable field for further examination.

The humus bodies in coal are by far the most resistant portion of the volatile matter to the solvent action of the pyridine, and are practically insoluble, but there are also undoubtedly some

* *Trans. North Eng. Min. Engineers*, 1899, 82-87.

§ *Ibid.*, 1908, 147.

Hosted by Google

forms of resin constituents in coal which are nearly insoluble.

Bedson found that the volatile matter in cannel coal varied very much in its solubility, whilst the hydrocarbons in shale were insoluble, and yet the destructive distillation of these bodies shows them to be very rich in resin constituents.

It appears probable that in a feebly coking coal the coking property is due almost entirely to the soluble form of resin constituents, and can, therefore, be entirely removed by extracting the coal with pyridine; whilst, on the other hand, in strongly coking coals the property is due partly to soluble resin bodies, but to an even greater extent to other hydrocarbons of resinic origin, which resist the solvent action of the pyridine, so that the coking property is weakened but not destroyed by extraction.

A similar conclusion was arrived at by Anderson and Roberts * in 1898 from an entirely different point of view. Dr. Percy, more than fifty years ago, pointed out the fatal effects of weathering upon certain coals and slacks, and showed that if a fairly good coking coal was kept at a temperature of 300° C. for a few hours, and is afterwards heated to redness, it does not swell and coke; and Anderson and Roberts, in trying this with various Scotch coals, found that, although it was true for a coking coal of medium power, a really strongly coking coal had the power only weakened, and they found also that the same phenomenon could be brought about by treating the two coals with sodium hydrate; and the conclusion is that although resinous bodies which can be saponified or oxidised contribute largely to the coking, yet there are also present non-saponifiable bodies, which, in breaking up under the influence of heat, yield enough luting to form coke; and I think the action of pyridine shows that this non-saponifiable body or bodies consists of substances very probably akin to those found in shale and some cannels.

Burgess and Wheeler,† in a paper read before the Chemical Society this year, took a Silkstone coal containing 33·4 per cent, of volatile matter, and succeeded in extracting 30 per cent. by means of pyridine, leaving a coke-like residue, which on distillation at 900° C. yielded hydrogen and oxides of carbon—they would have found methane as well if they had looked for it—whilst the extract on destructive distillation yielded a mixture of the paraffin hydrocarbons and hydrogen.

* *Jour. Soc. Chem. Ind.*, 1898, 1013.
† *Chem. Soc. Jour.*, 1911, 654.

At first sight this looks as if pyridine was a solvent which could be used to separate the humus and resin constituents, but Messrs. Burgess and Wheeler are careful to point out that "they hesitate to identify absolutely the paraffin-yielding constituents of coal with that portion extracted by pyridine," and they are wise in being cautious, as there are several anomalies to be cleared up. I have found several times that after extraction the residue contains as much and sometimes more volatile matter than the original coal, in spite of repeated washings with acid, drying in vacuo, and other forms of treatment intended to eliminate all pyridine; whilst the composition of the extract also shows anomalous results, and after the most careful measures have been taken to free it from pyridine, it will sometimes still contain more nitrogen than did the original coal.

It is to be noted that so far the two most successful coal solvents have been anilin and pyridine, both of them alkaline organic bases, and as we have seen that the effect of extraction by pyridine has been the same upon the coking power of the coal as treatment with sodium hydrate, which saponifies the resin constituents, it seems highly probable that the pyridine forms a compound with the resin bodies or some portion of them, and this compound is soluble in excess of pyridine, and if this is so, it should be traceable by the presence of nitrogen in the extract.

In an experiment made by Baker* he treated coal from the Hutton seam with pyridine, and after carefully freeing the residue and extract from pyridine, analysed them with the following results:—

20·4 per cent. extracted.

	Original Coal.	Residue.	Extract.
Carbon . . .	80·82	82·06	79·37
Hydrogen . .	4·66	4·85	5·79
Oxygen . . .	10·81	9·65	10·73
Nitrogen . . .	1·84	1·78	2·66 ?
Sulphur . . .	1·84	1·23	1·40

and he queries the nitrogen in the extract, evidently thinking it a mistake.

Anderson† also analysed a Bannockburn main coal and the matter extracted from it by pyridine:—

12·8 per cent. extracted.

	Original Coal.	Extract.
Carbon	86·70	83·39
Hydrogen	5·38	6·05
Oxygen	5·94	7·30
Nitrogen	1·98	2·86

* *Trans. North Eng. Min. Engineers*, 1901, 23–26.
† *Jour. Soc. Chem. Ind.*, 1898, 1013.

Hosted by Google

In each case there was a large increase in the nitrogen, and Baker's analysis of the residue shows that it did not come from the coal, and the probabilities are that the extract is a feeble compound of the resin body and pyridine. In the case of the Hutton coal, the coking power was destroyed by extraction, and in the case of the Bannockburn coal weakened.

The extracts when distilled gave very large volumes of rich gas, and left a strong but intumescent coke.

The residues after extraction show a still more remarkable anomaly. As it is manifestly the resin constituent which has been extracted, one would expect that on determining the volatile matter in the residue it would be found to be as much lower as the amount extracted, but it proves to be very nearly as high, and in many cases higher than in the original coal.

Anderson and Henderson, in their examination of coals by pyridine, give the loss of weight of the residues from the extraction on heating. which are here contrasted with the original volatile matter in the coal:—

Volatile.	I.	II.	III.	IV.	V.
In original coal .	31·98	39·89	46·59	27·4	36·78
In residue . . .	39·26	44·14	49·14	29·6	43·02
Per cent. extracted	10·8	7·0	21·7	12·8	14·5

This increase in the amount of volatile matter present in coal can mean only that the pyridine has attached itself to some constituent in the coal to form a compound insoluble in excess of pyridine, but the only analysis published of a residue with the percentage of nitrogen determined (Baker) shows no sign of this, as the nitrogen is the same as in the original coal, but the volatile matter in the residue is not given.

In an experiment upon a Durham coal (Londonderry) made in my laboratory, the following results were obtained:—

The coal lost 18 per cent. of its weight to the pyridine.

	Original ash and moisture free.	Residue from pyridine.	Pyridine extract 18 per cent.
Carbon . .	82·87	79·15	81·04
Hydrogen .	5·57	4·71	7·18
Oxygen . .	8·72	14·00+	7·98+
Nitrogen . .	1·68	2·14	3·80
Sulphur . .	1·16	not determined	not determined
Fixed carbon	63·00	64·46	,,
Volatile . .	37·00	35·54	,,

\+ oxygen plus sulphur.

In this determination, the increase in nitrogen over the amount present in the original coal in both residue and extract points to the presence of compounds of pyridine in both, whilst the increase in hydrogen in the extract, taken in conjunction with the decrease of hydrogen in the residue, points to its having been a resin body that was dissolved.

These considerations seem to make it clear that the resin constituents condition the coking of coal during destructive distillation, and that they are of at least two kinds—the one easily oxidisable, soluble in pyridine and saponifiable by alkalies, which on weathering is oxidised into a humus body with evolution of water and carbon dioxide, and is responsible for the heating of coal; the other class non-oxidisable, not saponified by alkalies, and forming with pyridine a compound insoluble in excess of the reagent, and this class may be the hydrocarbons from decomposed resins, as the residue in which they are present yields rich liquid hydrocarbons, as tar and pitch, but not rich gas.

My own opinion is that although pyridine is a better solvent for coal than any other of which we know, yet that it will never prove more than a useful first step in the separation and identification of the complex mixtures present in the coal, whilst even then pyridine has an awkward knack of attaching itself to other molecules, which makes it difficult to get rid of without using such drastic measures as are quite likely to alter the nature of the bodies dissolved in it.

Several observers are at work upon the problem, and it is to be hoped that satisfactory results will soon throw light upon this complicated subject.

Coal always contains a certain proportion of water, which appears to be held partly mechanically and partly in some form of combination, and in this it resembles wood, which after long air-drying still retains an average of 20 per cent. of moisture, which, if got rid of at an elevated temperature, is reabsorbed from the air. The mechanically held portion in coal is generally known as "pit-water," and represents ordinary wetting, which can be got rid of by air-drying; but the so-called "hygroscopic water" is driven out only by drying at 105° C., and as this heating for some hours causes oxidation of the resin bodies, it also tends to destroy the coking properties of the sample, a result which has led some observers to conclude that hygroscopic water is essential to coking, which is manifestly incorrect, as the tertiary coals, which contain the largest quantity of hygroscopic moisture, will not coke, owing to the proportion of humus derivatives being largely in excess of the resin bodies.

Hosted by Google

We have already seen that the ash of coal represents mineral constituents present in the sap of the original plants, or derived from the surrounding strata during the formation of the coal, whilst nitrogen, derived from the proteid bodies in the vegetation, is always present to the extent of 1 to 2 per cent., and is probably mostly borne by the humus bodies in the coal, which also are the most likely to be the carriers of the organic sulphur which has been clearly proved to be present, the bulk of the sulphur, however, being in the form of pyrites produced by sulphides from the reduction of mineral sulphates reacting upon iron salts infiltrating in solution into the coal measures.

Many classifications of coal have been suggested, some based on their chemical, some on their physical, and others on their coking properties, and of the latter the most generally adopted is that suggested by Gruner, in which he tabulates bituminous coals into five classes, and although Schondorff, Muck, and others have shown that it is not applicable to all kinds of coal, still this criticism applies to all classifications that have been proposed :—

In the third class the action still has continued with further concentration of the resin bodies, hydrocarbons and residuum, with the result that the former bodies are so increased in comparison to the humus and residuum that a good coke results, although, for reasons that will be discussed when speaking of coking processes, it is rather too porous and bulky.

In the fourth class the proportion of resin and hydrocarbon bodies has reached the right ratio as compared with the humus and residuum, and the best coking coal is obtained. Bituminous coals of the kind classified by Gruner may, therefore, be looked upon as an agglomerate of humus and the degradation products of these bodies down to carbon, luted and protected by resin bodies and their derivatives; steam coals and anthracite as the degradation products of humus which has nearly completed its decomposition owing to the small quantity of resin bodies in the original vegetation; cannel coal as consisting mainly of resin bodies, which, having been in a semi-fluid condition, have mingled with the earthy matter in contact with it, so obtaining the high ash found in many kinds.

			Carbon.	Hydrogen.	Oxygen.
1.	Dry coal	Long flame and non-coking	75–80	4·5–5·5	15·0–18·5
2.	Fat gas coal	Coke porous and brittle	80–85	5·0–5·8	10·0–13·2
3.	Semi-fat or furnace coal	Good coke, but porous	84–89	5·0–5·5	5·5–10·0
4.	Coking coal	Best coke	89–91	4·5–5·5	4·5– 5·5
5.	Lean coals and anthracite	Non-coking	90–93	3·0–4·5	3·0– 4·5

This arrangement shows not only the coking properties, but also the changes in composition which the coal undergoes, the concentration of carbon and reduction in highly-oxidised bodies.

In the first class we have the dry coals, yielding large volumes of gas and liquid products on distillation, and these, as might be expected, most resemble the lignites, and share with them the property of non-coking or binding together of the residue on carbonisation.

This is due to the fact that the humus-like bodies are still present in much larger quantities than the resinic compounds and hydrocarbons, and as on distillation they leave no binding material in the residue, the resinic bodies cannot supply enough to give more than a friable mass.

In the second class of coals altered conditions of temperature, pressure, and time have led to further decompositions of the humus bodies, and the resinic constituents and hydrocarbons having increased in ratio by concentration, a point is reached at which coking takes place, although not of a satisfactory character.

In putting forward this theory as to the composition of coal, I wish it to be distinctly understood that by the terms "humus" or "resin" bodies, I do not imply any one distinctive compound, but merely bodies of this character, the humus bodies all containing a percentage of hydrogen from 5 per cent. downwards, whilst the resin bodies all contain a percentage of hydrogen above 5 per cent. If it is once admitted that coal is a conglomerate of the kind I have indicated, it explains all those obscure points which no other theory touches—such as why with two coals of almost identical composition and of high oxygen content, one should be a coking and the other a non-coking coal; the reason being that in the one the high oxygen content is due to humus bodies, which will not coke owing to the low pitch-forming nature of the hydrocarbons, whilst with the other the oxygen is due to resin bodies which are essential to good coking.

In 1898 Anderson and Roberts,* as the result

* *Jour. Soc. Chem. Ind.*, 1898, 1019.

Hosted by Google

of a long research upon the chemical properties of Scotch coals, came to the conclusion that a considerable part of the organic matter in coal consists of a complex compound comparatively rich in nitrogen and also containing sulphur, and that there is also present resinous material, whilst the remaining constituents are composed of degradation products of the original carbohydrates of the coal plants—a theory which, in its essentials, agrees very well with my views on the subject.

During the present year Burgess and Wheeler* have published the results of a series of experiments upon the distillation of coals at various temperatures, which lead them to conclude that coal contains two types of compounds of different degrees of ease of decomposition. The most unstable decomposes below 750° C., and yields on distillation the paraffin hydrocarbons and no hydrogen; the other decomposes only at or above 750° C., and yields hydrogen only, or possibly hydrogen and oxides of carbon. The latter they suppose to be a degradation product of cellulose, the former to be derived from the resins and gums from the coal plants, and the authors consider that the difference between one coal and another is determined by the proportion in which these two types exist in the coal.

In 1907, whilst working on the "Coalite" process, I found that the possibility of making this smokeless fuel was dependent upon the fact that if the temperature of distillation of coal was kept at 400° C. to 500° C., all the liquid and all the heavy hydrocarbon products of its decomposition capable of forming smoke were evolved, the volume of gas amounting to from 4,000 to 5,000 cubic feet, whilst the coke still contained a residual compound that required a temperature of 700° C. to 1000° C. to decompose it, when a volume of gas nearly equal to the original yield was evolved, consisting of hydrogen and methane with small quantities of oxides of carbon, and it was this volatile compound which gave the coalite its ease of ignition and flaming combustion. This I stated in a Cantor Lecture at the Royal Society of Arts in 1908, when giving the principle of the manufacture of coalite, as follows: "Success can be achieved only by dropping the temperature to a scarcely visible heat (400° C), and when this is done the coke may be kept at it for almost any period without driving out those volatile hydrocarbons that give easy ignition and a smokeless flame."†

* *Chem. Soc. Jour.*, 1911, 649.

† *Journal of the Royal Society of Arts*, 1908, LVI. 853.

It is evident that this more resistant volatile residue is the body which Burgess and Wheeler consider a degradation product of cellulose, which on heating "yields hydrogen alone."

The error into which these observers have fallen in supposing that hydrogen alone is evolved is due to the fact that their assumptions have been based upon the composition of the gases evolved during distillation at successive stages of temperature and the use of very small quantities of material.

Had Messrs. Burgess and Wheeler used a larger quantity of coal and distilled out everything that would come over up to 600° C., and had then distilled the residue at 800° C. to 900° C., they would have found that at these temperatures the residues were still yielding a certain proportion of methane, which had been one of the most characteristic products of decomposition from the time when the vegetation first began its conversion into peat.

Another great mistake made by Burgess and Wheeler lies in supposing that of the two classes of compounds present in coal, one decomposes below 750° C., whilst the other decomposes only at or above that temperature and yields hydrogen only.

All the evidence that can be adduced shows that when a coal undergoes destructive distillation, all the hydrocarbons, together with the resin and humus constituents, undergo decomposition at a temperature certainly well below 700° C., and that, as the liquid and gaseous products distil out, they leave behind their less volatile residues as a pitch, which lutes together the carbon particles and forms soft coke, whilst as the temperature rises above 750° C., the pitch residue decomposes, yielding hydrogen, carbon monoxide, and methane as gases, whilst the carbon residue from the pitch binds the residual mass into coke, and it is this residual pitch that Burgess and Wheeler have mistaken for a primary constituent of coal.

It is clear, however, that (putting detail on one side until our knowledge has been broadened by experience) the answer to the question as to what is the composition of coal—whether the answer is derived from a consideration of the actions taking place during its formation and of the substances from which it was derived, or is obtained from analytical data, as was done by Anderson and Roberts, or from the products of distillation, as has been attempted by Burgess and Wheeler—must be that coal is a conglomerate of humus and its degradation products with the resinic bodies and their derivatives.

INDIAN SECTION.

A meeting of the Indian Section was held on Thursday, December 14th, 1911, Sir Steuart Colvin Bayley, G.C.S.I., C.I.E., Vice-President of the Society, in the chair.

The Chairman, in introducing the reader of the paper, said he had no doubt many of those present were already well acquainted with Dr. Jenkins's name and fame. The author had had a long experience in superintending the sea fisheries on the western coast of England, and a few years ago he was deputed at the instance of the Government of Bengal to advise and assist them in inquiries into the possibility of deep-sea fishing principally in the Bay of Bengal. He was therefore exceedingly well informed, and better able than most people to give information upon the subject which he was bringing to the notice of the members of the Society in his paper.

The paper read was—

THE FISHERIES OF BENGAL.

By J. Travis Jenkins, D.Sc., Ph.D.,
Superintendent of the Lancashire and Western Sea Fisheries.

Recent investigations into the fish and fisheries of the Province and Bay of Bengal date from the appointment of Sir (then Mr.) K. G. Gupta, in July, 1906, to inquire into and report on the fish resources of Bengal. Previously but little was known of the possibilities of fishing in India; its gigantic rivers and estuaries and its vast areas of potential trawling ground had never been examined from the standpoint of modern commercial fishing.

Sir K. G. Gupta, in the first place, reported on the conditions prevailing in Bengal, and afterwards visited Europe and America. The results of his tour were incorporated in a second report, which contains not only a narrative of his observations, but also a summary of his recommendations for the improvement of the fisheries of Bengal. As these reports* are available for reference, it is not proposed to discuss them in any detail here. Numerous valuable recommendations were made in the second report, and if these had been properly carried out, there can be little doubt that a permanent improvement in the fish supply of the Province would have resulted.

The four principal suggestions made by Sir K. G. Gupta were:—

1. An exploration of the deep-sea and estuarine resources of the province.

2. A study of the migrations and the spawning-grounds of the hilsa.

3. The cultivation of the species of Bengal carp (catla, rahu, etc.).

4. The establishment of a permanent organisation for the development and control of the fisheries of the Province.

Sir K. G. Gupta retired from the Indian Civil Service in February, 1908, and the control of the fishery investigations was transferred to an officer with the title of "Commissioner of Fisheries," under whose management they remained until March, 1910.

Early in 1908 I was approached by the India Office and invited to go to Bengal to act as "Adviser to Government on Fishery Matters," and in October I proceeded to Calcutta for a period of eighteen months for that purpose. Meanwhile a second-hand steam trawler (the "Golden Crown") had been purchased by the India Office for the survey of the Bay, and this vessel left England in February, 1908, with an agreement for a two years' fishing voyage in the Bay of Bengal. After sundry alterations in Calcutta, which materially affected the fishing capacity of the vessel, she started on her first fishing voyage on June 10th, and at the entrance to the Eastern Channel encountered the bad weather of the onset of the S.W. monsoon. Fishing was, however, persevered with in Balasore Bay and elsewhere. My first voyage in this trawler was in November, 1908, to the Arakan coast, and subsequently I took part in voyages to all parts of the Bay visited by the "Golden Crown," so am able to speak from personal experience of the possibilities of trawling. Steam trawling is probably the most successful modern method of fishing in temperate waters. At any rate, out of about seven and a half million pounds' worth of fish landed in England and Wales during 1909, no less than six million pounds were trawl-caught fish. A trawl is a conical or bag-shaped net, which is "shot" from the steamer's side and is towed along the bottom astern while the steamer moves ahead at a slow rate of speed (usually from three to four miles per hour). Commercial trawling is only possible up to depths of about 100 fathoms, so that our experiments in the Bay of Bengal were confined to a somewhat narrow area near the coast. In all, the "Golden Crown" made twenty-eight voyages to the Bay,* and only on one occasion was the weather so bad that fishing was impossible. This was in November, 1909, off the Arakan coast, when a cyclonic storm was encountered. During all these voyages trawling was tried in depths varying

SKETCH CHART SHOWING GROUNDS TRAWLED OVER BY THE "GOLDEN CROWN"
(June–December, 1908).

from 14 to 70 fathoms, from Calingapatam, in the Presidency of Madras, to Akyab, on the Burmese side. From time to time interim reports on the work of the trawler appeared in the *Calcutta Gazette*, and for the details of the voyages these should be consulted.* One ought, perhaps, to explain here that a steam trawler engaged in fishing for commercial purposes trawls during the whole of the twenty-four hours, and this rule was followed on the "Golden Crown." All modern trawlers are fitted up with two sets of fishing gear in readiness for immediate use, one on the port side and the other on the starboard side, so that as soon as one net is hauled, the other may be shot. As noted above, the alterations made to the "Golden Crown," on her arrival at Calcutta, made her starboard gear useless, with the consequence that when we were on the fishing grounds, frequent annoying though unavoidable delays occurred. Whilst surveying unknown grounds, it is impossible to avoid damage to the net, and all this damage had to be repaired before the net could be used again. Even a Commissioner of Fisheries could see the inutility of fishing with a net which had a large hole in it. Many hours were spent idly at sea while all hands were repairing the net, and this should be taken into account in estimating the weight of fish caught per day's trawling. Moreover, in shooting the net, account has to be taken of the direction of wind and tide, and it will be obvious even to landsmen that with a vessel only capable of using her port gear, much time would be lost in manœuvring her into position for shooting and hauling.

As a rule, the "Golden Crown" made four hauls a day—at daybreak, at noon, just before sunset, and at midnight. For the last haul the acetylene gas installation on board was used but, even so, the sorting of specimens was attended with some difficulty. The largeness and frequency of the hauls made it practically impossible for any scientific work to be done on board. Typical specimens of fish and the various groups of invertebrates were preserved, and the localities from which they were obtained were noted. On arrival at Calcutta, the collections were transferred to the Museum, where they were arranged into groups, so that each separate group might be sent to a specialist for report. Broadly speaking, the "Golden Crown" trawled over four fairly distinct areas. These are:—

1. Commencing near the Mutlah Light Vessel (off the entrance to the river of that name), and extending to the westward past the entrance to the Eastern Channel (leading to the Hooghly) down to the Pilot's Ridge Lightship.

2. Off the Arakan coast from the South Patches Lightship, at the entrance to Chittagong, to Oyster Island, in the vicinity of Akyab.

3. The coast of Orissa from the mouth of the Devi river to the entrance to Lake Chilka.

4. The coast of the Ganjam district of the Madras Presidency from Ganjam to Santapilli Lighthouse (in Vizagapatam district).

In the first area, the bottom of the sea consists of an extremely fine and soft mud. Here, in order to trawl successfully, the vessel had to be kept going at a fairly good rate of speed, as otherwise the net would have become immovably imbedded in mud. This mud is, of course, derived from the deposit of particles brought down by the rivers of the Gangetic delta. A large number of the empty shells of a species of dentalium (a scaphopod mollusc) is met with here. Peculiar round balls of mud are brought up in the trawl, and these, when opened, are found to have a species of mussel (alive) inside. Generally speaking, on these muddy grounds the invertebrate fauna is scanty, and the vertebrate fauna (fish) quite distinctive and in marked contrast to any of the other areas. Gigantic skates and rays, huge ferocious congers, enormous ground-sharks and saw-fish are the most characteristic forms. The "Bombay Duck," a few soles, and an occasional shoal of pomfrets comprise the more valuable commercial species of this area. In the second area the ground varies considerably. Near the South Patches Lightship it is muddy; further to the south this becomes replaced, in depths from 8 to 17 fathoms, by fine glittering sand with patches of shells at intervals. Off St. Martin's Reef, in from 10 to 13 fathoms, fishing was conducted on grounds consisting of shells and fine gravel. Between St. Martin's Reef and Oyster Island the trawl brought up fossiliferous rocks of Miocene Age, specimens of which were handed over to the Geological Survey of India. As the "Golden Crown" was not provided with gear suitable for trawling on rocky ground, these localities had to be abandoned before they had been properly explored, though I am fairly certain that, with proper nets, trawling could be successfully carried on in this area.

The predominant feature of the bottom in the third area was sand, which, in depths of 25 fathoms and upwards, was replaced by mud.

* *Vide Calcutta Gazette* Supplements, March 24th, June 16th, August 4th, October 13th, 1909.

Hosted by Google

Off the Black Pagoda (Konarak) there is a reef of a recent conglomerate of sand and decomposed shells, where on one occasion the trawl was lost. Off the mouth of the Devi river turtles were unusually abundant, no less than six being taken in a single haul of the trawl. This region turned out to be a better trawling ground than either of the two previous areas, the proportion of fish which would be classed by the trade as "prime" being relatively high.

Sparoid fish (bearing a superficial resemblance to the "John Dory" of home waters), mackerel and horse-mackerel were the most typical fish of this area.

In the fourth area, off the Ganjam coast, the bottom in shallow water was sand, changing into mud in greater depths. In the southern part of this area the ground became more varied. Off Gopalpur, in depths of 24 fathoms, enormous numbers of shells of a species of mollusc were found interwoven into rock-like masses with a sponge. The more solid nature of the ground here furnishes a holding place for gigantic fan-like corals (*Antipatharia*). The fish of this area were quite distinctive, and for the first time true coral reef denizens were captured.

The "Golden Crown" Fish.

The question of the kinds, quality, and quantity of trawl-caught fish in the Bay of Bengal is one of the greatest commercial importance. Obviously, the scientific names of the different species would convey little or no idea to most people of the various characteristics—appearance, flavour, and digestibility—which render fish marketable or otherwise. Consequently, it is necessary to take the names given to the fish by the European crew of the "Golden Crown," with the minimum of explanatory notes to make them intelligible.

In some cases the crew of the trawler adopted local names (not always correctly), and in other cases utilised the common names of European fish, on account of some superficial resemblance, or they even invented entirely new names for fish which were quite unlike any common European marine species.

The local names adopted for the purposes of classification were bhekti, bummaloh, topsi, and pomfret. The pomfret is a well-known species, and needs no description. The bummaloh is a kind of marine catfish, and is well known to Anglo-Indians as the "Bombay Duck." The topsi was not real "topsee much" of the estuaries (*Polynemus paradiseus*), but two allied species (*P. indicus* and *P. plebeius*). The bhekti of the "Golden Crown" was not the bhekti (*Lates calcarifer*) of Bengal, but comprised two or more forms, notably a species known locally as the datneh (*Chrysophrys datnia*), and several percoid forms. Of the names applied to fish in the Bay which have been adopted on account of the presumed similarity to European species, the chief are whiting, herring, gurnards, halibut, conger, prawns, skate, soles, lobster, rock salmon, and cod. Of these the whiting, gurnard, and rock salmon are structurally very dissimilar to the European forms of the same name. The *Gadidæ* (cod, whiting, etc.) are only represented by one minute form in Indian waters, and the so-called whiting of the "Golden Crown" included a number of different species of scienoids, a family represented occasionally in British waters by the "meagre." The cod were really large perch-like forms (*Serranidæ*). The rock salmon was *Otolithus maculatus*, a scienoid with a spotted surface, not altogether unlike a salmon in appearance; it is perhaps hardly necessary to add that there are no indigenous *Salmonidæ* in Indian waters.

The "gurnards" were siluroids (catfish), for the most part belonging to the genus *Arius*. It is not surprising that the crew of the trawler were very wide of the mark in this guess, as siluroids are quite unknown in the home markets. The name was undoubtedly given on account of the hard bony plates protecting the head, which are found in both forms.

Of the true flatfish (*Pleuronectidæ*), the "halibut" was *Psettodes erumei*, which is more like the flounder than the halibut in appearance. True soles are absent in the Bay of Bengal, though allied forms of the genera *Cynoglossus*, *Synaptura* and *Plagusia* were by no means rare. The "conger eel" was *Murænesox cinereus*, and the "skates" invariably sting-rays. The herring and mackerel were sufficiently like the home species to justify their names, as were also the prawns and lobsters. The unintelligible divisions of "red flats," "small flats," included all those numerous species of different genera which bore a superficial resemblance to the "John Dory."

The table at the end gives the details of the fish captured by the "Golden Crown" (see Appendix II.). From this summary it will be seen that the average catch for the whole period was 26·6 cwts. per day's trawling. For comparison, a statement is appended showing the average catch in cwts. per day's absence from port of first-class English steam trawlers during

Hosted by Google

1909, that being the last year for which statistics are available*:—

Region.	Cwts. of Fish per Day.
White Sea	59·88
Iceland	43·61
Rockall	39·51
Faroe	34·94
North of Scotland	26·50
West of Ireland	25·82
Southward of Ireland	25·81
Westward of Scotland	23·88
Biscay	17·28
North Sea	16·95
Bristol Channel	14·95
Irish Sea	14·38
English Channel	13·61
Portugal and Morocco	8·58

As regards weight of fish caught, Indian waters are roughly equivalent to those of the North of Scotland. In making this comparison, it must be noted that the figures given for the "Golden Crown" are cwts. per day's fishing, whereas those for the English trawlers are per day's absence from port. On the other hand, most of the English trawlers referred to, especially those visiting the more remote fishing grounds, are much larger than the "Golden Crown," are fitted with more varied and powerful gear, and are run on strictly commercial lines. On several occasions the "Golden Crown" made very large hauls, nearly, and in some cases over, a ton weight of edible fish (excluding sharks) for a haul lasting from four to five hours. For instance:—

Voyage 18.—February 11th, 1909. Off Eastern Channel entrance. Pilot ship bearing N.W. by N., about seven miles. Haul made at noon. Gurnards, 676 lb.; mackerel, 427 lb.; pomfrets, 273 lb.; whiting, 131 lb.; congers, 100 lb.; skate, 35 lb.; bhekti, 32 lb.; halibut, 12 lb.; soles, 5 lb. Total, 1,691 lb.

Voyage 24.—September 29th, 1909. Gopalpur, bearing N.W., depth 25 fathoms. Haul made at 5 p.m. Gurnards, 560 lb.; whiting, 460 lb.; small flats, 375 lb.; bhektis, 320 lb.; prawns, 260 lb.; red flats (*Pagrus spinifer*), 70 lb.; skate, 60 lb.; cod, 30 lb.; conger, 10 lb.; mixed, 10 lb. Total, 2,255 lb.

Voyage 25.—October 16th, 1909. Santapilli light bearing W.N.W. about sixteen miles away, the depth being 28 fathoms. Haul made at 5.30 p.m. Bhektis, 835 lb.; small flats, 530 lb.; whiting, 450 lb.; gurnards, 400 lb.; prawns, 240 lb.; pomfrets, 8 lb. Total, 2,463 lb.

Voyage 27.—November 27th, 1909. Black Pagoda (Konarak), bearing N.½E., depth 15 fathoms. Hauled at 11.30 p.m. Prawns and whiting, 480 lb. apiece; gurnards, 350 lb.; small flats, 340 lb.; bhektis, 65 lb.; skate, 20 lb.; pomfret, 20 lb.; soles, 12 lb. There were also two turtles taken this haul. Total weight (excluding turtles), 1,767 lb.

Practical Results of the "Golden Crown's" Investigations.

Indian officials who had experience of Indian waters previous to 1908 had emphatically pronounced in favour of the enormous wealth of fish-life to be found there. Lieutenant-Colonel Maxwell, C.I.E., who was formerly in charge of Burmese fisheries, stated that in his opinion "wealth beyond the dreams of avarice" awaited the persons who first had the courage to exploit the fisheries of India in a modern fashion. Lieutenant-Colonel Alcock, formerly Superintendent of the Indian Museum at Calcutta, and naturalist on the Royal Indian Marine Survey Ship, the "Investigator," was equally confident. He wrote: "The sea fisheries of the Bay of Bengal are of a value well-nigh incalculable. That they are unknown, uncared for, and unappreciated, is unfortunately true; but it is equally true that they will prove a mine of wealth to whoever may have the enterprise to exploit them and the tenacity of purpose to work them in the face of the apathy and incredulity that at present exist regarding them."

Before a successful trawling company can be established, there are many things to be considered. Some of the problems were solved by the "Golden Crown" investigations; others remain to be dealt with in the future.

One of the most important factors for consideration is the climate. Can fishing be carried on regularly in the Bay of Bengal by modern steam trawlers in all weathers? The experience of the "Golden Crown" enables us to answer this most important question in the affirmative, so that it is possible to secure a regular and constant supply of fish for the markets. Trawling was, as a matter of fact, carried on in every month except May, and there can be no doubt that if the "Golden Crown" had not been laid up for repairs, she would have gone out that month as well.

On reference to the table (see Appendix II.), it will be seen that only one voyage out of twenty-eight was entirely unproductive. On this voyage (No. 26) a cyclonic storm was encountered on November 14th, 1909, off the Burmese coast near Akyab. A lot of water was shipped, the provisions were spoilt,

* Annual Report of Proceedings under Acts relating to Sea Fisheries for the year 1909. Board of Agriculture and Fisheries. Cd. 5874. Price 2s. *Vide* p. lviii. Table B.

Hosted by Google

and the trawler had to return to Calcutta without any fish. Although she was by no means as seaworthy as the most modern type of trawler, the "Golden Crown" trawled right through the S.W. monsoon of 1908, and during 1909 she trawled in September, October, and November, when exceptional weather was encountered.

The climate also affects the possibility of keeping fish fresh. It was proved by the "Golden Crown" investigations that it is possible to land sea fish in a fresh condition in Calcutta from places as far distant as Akyab and Santapilli, and, moreover, this fish had undergone no deterioration in quality, appearance, or flavour. The fish, when caught, were washed in clean sea water, and then (with the exception of the soles, which were gutted) placed in the hold in ice in an ungutted condition.

As will have been gathered from the preceding remarks, the quantity of fish captured per day's trawling compares favourably with many British fishing grounds, in spite of the handicaps under which the "Golden Crown" laboured. The fish to be obtained in the Bay are, for the most part, of excellent appearance and taste, and should command a quick sale in the Calcutta and up-country markets. Even the coarsest varieties could be disposed of to the poorer classes.

The only inedible varieties are the sharks and the saw-fishes, and even in these forms the fins and livers could be utilised. In some of the larger saw-fish I dissected, the liver alone weighed over a hundredweight. The weight of sharks and saw-fish is not included in the table in the Appendix, and only on two occasions is the weight of fins given. It may not be out of place to mention here one or two other matters that would have to be considered very carefully by any company that proposed to exploit the Bay with steam trawlers. The greatest difficulty is undoubtedly pilotage. As most of you know, Calcutta is situated a considerable distance from the open sea, and is approached by a river—the Hooghly—which is one of the most difficult in the world to navigate. No vessel is allowed to move in the river after dark, and when the tide is unfavourable, the journey from Calcutta to the open sea frequently takes two days. The pilotage dues are necessarily heavy. Moreover, even when moored in the river opposite Prinsep's Ghat at Calcutta, the discharge of fish is attended with difficulties which have to be seen to be realised. For these reasons, I am inclined to recommend the claims of Diamond Harbour in preference to Calcutta as a trawling base. Diamond Harbour is merely a tidal creek, with no facilities at present for trawling, but it possesses numerous advantages over Calcutta. In the first place, it is much easier of approach from the sea, some of the most difficult shoals including the celebrated "James and Mary," being situated above it. A master of a steam trawler, after some experience of the locality, ought to be able to pilot his vessel without assistance.

Diamond Harbour is connected with Calcutta by a branch line of the Eastern Bengal State Railway, so that perishable goods could be rapidly transported there. Coal and fresh water could be brought down by launches or country boats, whichever was cheaper. Land for building purposes could be obtained at a cheaper rate than in Calcutta, and there should be no difficulty about coolie labour. Coal and water are both cheap, but ice is expensive, and it would certainly pay any trawling company to make their own ice. There is no Customs duty on fresh fish, and the harbour dues (if any) would be very moderate. There are no laws or regulations restricting trawling in any manner in the Bay of Bengal, and none will probably ever be required. There would be no opposition to trawling by native fishermen, as the natives do not fish in the open sea except to a very limited extent off the Madras coast. The fish merchants in Calcutta might, and probably would, attempt to boycott trawl-caught fish, since it would tend to interfere with the large profits they at present enjoy. Hands for deck and engine-room work can be obtained at cheap rates, but in my opinion no trawler could fish successfully in the Bay of Bengal with less than two Europeans on board.

Scientific Results of the "Golden Crown's" Investigations.

On board the trawler at sea it was impossible to do any work beyond the sorting of specimens into groups and their preservation in formalin or spirit. The collections were taken to the Indian Museum and there prepared for identification. The influx of a large number of species of fish and marine invertebrates, some of the former of huge size, threw a great deal of additional work on to the Museum staff. It is with great pleasure that I take the opportunity of recording my warmest thanks to the Museum staff, not only to Dr. Annandale, but to all his assistants for the help they afforded.

The necessity for the revision of the fishes of India is one of the points which the collection

Hosted by Google

of the "Golden Crown" (and others made in various parts of India by the Museum staff) has brought into prominence. Day's work was completed in 1878, since when large collections have been made, new species have been described, and doubts thrown on the correctness of some of Day's descriptions. As regards the "Golden Crown" fish, certain groups were worked out by Dr. Annandale. The cartilaginous families of the skates and rays, saw-fish and ground-sharks, were revised and brought up to date. Of bony fish, the flatfish (*Pleuronectidæ*) and the *Plectognathi* and *Pediculati* have been dealt with.

The cartilaginous forms (*Batoidei*), such as skates and rays, are, for the most part, species which live on the bottom of the sea, and are consequently commonly caught in the trawl. In his report Dr. Annandale* says:—

"Of the fifty-three distinct species of *Batoidei* here recognised as occurring in Indian seas, no less than thirty-three have been taken during the past year (1908–9) by the "Golden Crown." Of the remaining twenty, seven probably live only in water deeper than that in which the operations of the fishery steamer have been conducted, while at least four (the members of the family *Ceraptopteridæ*) are surface forms, and would not usually be taken in the trawl. In the list there are twenty-one specific and two varietal names not to be found in Day's volume in the "Fauna of India," or there regarded as synonyms. Of these, nine belong to species described within the last few years by Alcock or Lloyd, and, with two exceptions, taken in deep water by the "Investigator," while twelve are here recorded for the first time, or have recently been recorded for the first time in the Records of the Indian Museum. A new genus, five new species and a new variety, are described in this report."

Of the *Plectognathi*,† sixty-one species are known from Indian Seas. Of these, seventeen only were taken by the "Golden Crown." This is because the *Plectognathi* are reef-haunting species for the most part, and were only found in any variety towards the southward limits of the trawler's explorations. In this group a new species of *Triacanthus* has been described by Mr. Chaudhuri from the "Golden Crown" collections. Of the *Pediculati*, out of twenty-five species, twenty are deep-sea forms. Only three were taken on the trawler, but one of these was a new species.

* See Memoirs of the Indian Museum, Vol. II. No. 1. Report on the Fishes taken by the Bengal Fisheries' steamer "Golden Crown." Part I. Batoidei. By N. Annandale. Calcutta. Baptist Mission Press. May, 1909.

† See Memoirs of the Indian Museum, Vol. III. No. 1. Report on the Fishes taken by the Bengal Fisheries' steamer "Golden Crown." Parts II., III., and IV. By Annandale and Jenkins.

A revision of the flatfish (plaice and soles) belonging to the *Pleuronectidæ* collected in the Sunderbans on the "Ila," at sea on the "Golden Crown," and elsewhere in India by the Museum staff, revealed the existence of five new species.

For particulars of the various groups of invertebrates, the Records and Memoirs of the Indian Museum should be consulted. A bibliography of the papers dealing with the scientific work on the "Golden Crown" collections has been prepared and will be published in a paper* on the fauna of the Bay, which is at present in the press.

THE INVESTIGATIONS IN THE SUNDERBANS.

Although I repeatedly applied† to the Commissioner of Fisheries for the use of a launch for the exploration of the fisheries of the rivers and estuaries of the Sunderbans, it was not until the end of August, 1909, that a vessel was placed at my disposal. On three separate occasions in 1909—*i.e.*, in August, November, and December—the "Ila," a steam launch of the Salt Department, was employed on a fishery survey of the Sunderbans. This vessel, though well adapted for journeys in confined waters, was not built for fishery work, and the very confined deck space, the obstructions aft, as well as the absence of a steam winch, all hindered our investigations. Had a preliminary survey been possible in the cold weather of 1908–9, much valuable information as to the local conditions would have been obtained, and suitable fishing gear could have been ordered for extended operations in the following year. As it was, we had to do the best we could with a few nets which were only suitable for fishing in the open sea.

The nets used were a fish-trawl and a shrimp-trawl attached to a twenty-foot wooden beam, and herring and mackerel drift-nets. Various adaptations were tried with a view of suiting these nets to the local conditions, and although the results were not on the whole encouraging, a great deal was learnt of the peculiarities of the local fish and the possibilities of their capture on a commercial scale provided suitable gear was employed. The crew of the "Ila," who were without exception natives of India, very quickly learnt to handle the trawl and drift-nets, and I am pleased to be able to bear witness to their intelligence, adaptability, and willingness.

The first voyage was to the districts of the 24-Parganas and Khulna, and lasted from

* In the Records of the Indian Museum.

† The first occasion being on October 31st, 1908.

Hosted by Google

August 20th to 29th, 1909. Both trawl and drift-nets were tried in the creeks and the large rivers, the depths in the latter being anything from 6 to 10 fathoms. This time of the year, at the end of the rainy season, the whole country was flooded, and, owing to the currents in the rivers being at their strongest, fishing was more difficult than in the following voyages, which were carried out in the cold weather. In no instance were large hauls made, but still some interesting specimens were captured. On August 25th, when fishing with the shrimp-trawl off Morrelganj, a good haul of soles, bholas (*Sciœnoides pama*), and siluroids was obtained. These fish were taken at the bottom of the river, at a depth of 10 fathoms, a place inaccessible to the local fishermen's nets. The soles were quite unlike any previously met with in Indian waters, being much more slender than any known species. These fish were subsequently described as two new species of *Cynoglossus*.

The second voyage was confined to the district of the 24-Parganas, and lasted from November 10th to 21st, and on this occasion much better results were obtained, in spite of the obvious unsuitability of the nets for creek and channel fishing. Good hauls were made with fixed nets in a creek near Chennia, and the shrimp-trawl yielded fair quantities of shrimps, prawns, and bummaloes in 4 to 5-fathom water in this vicinity. The sea face would appear to be the most promising locality in the Sunderbans in the cold weather, and with suitable nets Fraserganj ought to be capable of commercial exploitation. The third voyage was also to the districts of 24-Parganas and Khulna, and lasted from December 5th to 16th, 1909. Similar experiments were tried, and the nets were, as far as possible, adapted to suit the local conditions. There can be no doubt that a properly-managed scheme for the development of the fisheries of the Sunderbans would be successful, the chief drawbacks at present being lack of fast transport and the fact that fishery operations are not sufficiently systematic and carried out on a large enough scale. The limited survey of the "Ila" proved that the Sunderbans are well stocked with fish of economic importance.

The estimated area of the Sunderbans in the Province of Bengal is 5,700 square miles, and obviously it was impossible to explore the fishery resources of this vast region in thirty-five days. Every variety of waterway is met with, from gigantic rivers several miles in breadth, with a fierce rush of tide, to tiny stagnant back-waters where the decaying vegetation gives off a pronounced odour of sulphuretted hydrogen and where fish life is an impossibility. The banks of rivers and creeks are alike composed of soft mud, except near the sea face, as at Fraserganj and the mouth of the Bungarah river, where a firm sandy beach is seen. In the unsettled tracts, dense impenetrable jungle grows right down to the water's edge, and in the tidal regions the stems and roots of the trees are densely encrusted with barnacles. This has probably given rise to the idea which is prevalent in Calcutta—that there are vast quantities of oysters in the Sunderbans. No edible mollusca of any kind were seen at the places visited by the "Ila." The water of the Sunderbans rivers and creeks varies from perfectly fresh through increasing degrees of salinity, till at the mouths of the larger rivers it approximates to that of sea water, though water of the salinity of the open sea was never encountered. Naturally the fish fauna varied with the salinity, depth, and other environmental conditions.

At the commencement of the rainy season the famous hilsa (the Indian shad) makes its annual journey from the sea to its spawning grounds in the higher reaches of the Ganges; and in certain parts of the Sunderbans, such as Khulna, there is an extensive fishery for this fish. Coarse fish, such as skates, rays, and sharks, did not appear to be very abundant. On the other hand, the catfish (*Siluridœ*) were very frequently taken. In fresh-water species of macrones (*Air*) and in brackish water *Osteogeniosus*, *Arius*, and *Pangasia* were caught. The development of the young in the mouth of the male parent was observed in two species of siluroids. In November, when fishing with drift-nets at Fraserganj, a number of specimens of *Osteogeniosus militaris* were captured, and in the mouths of the males a series of fertilised eggs were seen. These eggs showed the stages of development from the recently fertilised to that in which the yolk was almost completely absorbed. Apparently, even after development is complete, the young seek shelter in the mouth of the parent fish, since in the Culputooa River, on August 22nd, a specimen of *Arius jatius* was taken in the shrimp-trawl, in which three young ones were so sheltering.

Other valuable fish met with in the Sunderbans are the bummaloh, or Bombay duck, the bhekti, the datneh, the bhola (*Sciœnoides pama*), the cuja bhekti (*Sciœna cuja*), and the grey mullets, all of which would be considered prime fish in England.

A summary of the fishing "log" of the "Ila" is printed as an Appendix (No. III.). As in the case of the "Golden Crown," collections of typical fish and invertebrates were made and deposited in the Indian Museum.

The question of the development of the Sunderbans ought not to be considered apart from the other coastal fisheries of Bengal, and consequently a brief reference must here be made to the fisheries of Puri and Lake Chilka.

Puri and Lake Chilka.

At Puri the fishing is carried on by Telugus in the fine weather by means of masula boats, in the S.W. monsoon with catamarans. The masula net is really a gigantic seine. One end of the seine is attached to a rope, which is left with a party on shore. The net itself is placed in the masula boat, and paid out gradually as the boat makes a semicircular sweep beyond the surf. When the whole net is paid out, the boat comes ashore with the rope attached to the other end of the net. The net is then hauled up on the beach, the fish being captured in a pocket at the tail end. Very large hauls are frequently made by these Telugu fishermen in this manner. In rough weather the catamarans are used. One is hardly justified in applying the term "boat" to the four pieces of wood which, when lashed together, constitute the catamaran. Apparently the net used is a sort of drift-net, but I was unable to see this net at work. There is practically no attempt to preserve or cure fish for the market apart from merely drying them in the sun. This drying is customary both for small sprat-like fish (kanagurta) and for the larger mackerel (kokile). The fish are simply spread out singly on the sand and allowed to dry in the sun. Apparently no salt or other preservative is employed.

It would be difficult, if not impossible, to improve on the methods of fishing employed by these Telugus. They are admirably adapted for such a coast, where there is a heavy surf even with north-easterly winds. The absence of any suitable harbour or roadstead renders the introduction of the type of vessel used in England for inshore fishing impossible.

In Lake Chilka the methods of fishing are, briefly, two in number. Firstly, there is a seine net, the burra jal; and, secondly, there are fixed engines, stake "nets," or, rather, bamboo enclosures, in which the fish are trapped. Here, again, it is doubtful whether much, if any, improvement on the local methods of fishing can be devised. Some time previous to my visit to Chilka some European (Norwegian) fishermen attempted to exploit these fisheries, but without success.

Probably if any more efficient methods were adopted, the result would be a depletion of the fish stock in the lake and a permanent diminution of the supply. The burra jal has an enormous sweep, and must be sufficiently destructive in the confined waters of the lake. The method of fishing is, allowing for the different conditions, similar to that of the Telugus at Puri. The fish, however, instead of being landed on the shore, are driven up two narrow lanes of netting, and baled out with baskets. Of the fixed instruments there were numerous varieties, ranging from the enormous bamboo enclosures on Nalbano Island to small semicircular enclosures consisting of a number of basket-like traps.

Unlike the Telugus at Puri, the Ooriyas of Lake Chilka have a very fair idea of curing fish. The fish are split open down the middle of the back, the entrails removed and the inside is then sprinkled over with salt and placed out to dry in the sun, sometimes on bamboo stages erected on the lake, sometimes on the ground outside the fishermen's huts. Some of the larger fish were cut up into slices before salting. The question of the encouragement of a trade in salted fish is hardly one that can be entered into here. It was, however, considered carefully by the Fishery Board, but apparently the practical difficulties were insurmountable; at any rate, nothing had been done up to early in 1910. Although, in my opinion, there is a great future for what I may call the fresh fish trade in Bengal, it must not be understood that this would necessarily exclude the preservation of fish. It would be rash to generalise from the experience of a few months only, but from what was seen at Lake Chilka, it is more probable that a trade in salted fish would spring up gradually, provided the duty were remitted, than in any other way. The introduction of European methods of curing might prove of advantage in some of the larger centres, but one would prefer to see the local fishermen develop their own resources with duty-free salt.

Development of Sunderbans and other Local Fisheries.

The chief problem to be solved in the development of the fisheries of Bengal is the question of transport. There can be no doubt (1) That the supply of fresh fish in Calcutta and up-country markets within a day's journey is quite inadequate to meet the demand; and (2) That there is a large quantity of edible sea and

Hosted by Google

estuarine fish of the highest quality available within easy reach of Calcutta.

Since this fish can be purchased from the local fishermen far cheaper than it could be caught by any other means, there seems to be no reason for introducing European or any other methods of fishing, except in places like Fraserganj in the Sunderbans, where there is no community of indigenous fishermen and an abundant supply of fish.

Fresh fish always commands a quicker sale and a better price than any cured fish, and consequently I believe that any company which might be formed to develop what is only done now spasmodically—a trade in fresh fish preserved in ice for the Calcutta market—ought to be very successful, if at all reasonably managed. In my report to Government on the result of the estuarine investigations carried out on the "Ila," I pointed out the reasons why the development of the estuarine fisheries should pay, and the lines along which such development should proceed. An estuarine fishery would possess several advantages over any other:—

1. A much smaller capital would be required than in the case of a steam trawling company. To equip and maintain a small fleet of motor launches would cost far less than a corresponding number of steam trawlers. These launches would be mainly used for transport, which is the chief difficulty in the way of development of the fisheries.

2. The risk of casualties and delays in the supply to the Calcutta market consequent on the weather would be much less than in the case of deep-sea trawlers.

3. The development of the estuarine fisheries would be independent of the importation of European labour, and would consequently cost much less than steam trawling, where, in my opinion, Europeans could never be dispensed with. In an estuarine fishery it is rather by improving and modifying the local methods of fishing than by introducing foreign methods which may prove unsuitable to local conditions, that success is to be anticipated.

4. The taste and good qualities of the estuarine fish are already well known to the population of Bengal, whereas sea fish are not so well known, and are certainly less appreciated. In the estuaries there are fish suited to the taste and means of all classes of the population. The bummalohs, bhektis, cuja bhektis, mullets, shrimps, and prawns compare favourably with the best of fish anywhere, while the siluroids, gobies, and others would suit persons of moderate means. When one considers the class of fish found on the tables of well-to-do up-country residents at present, it seems almost incredible that no attempt has been made to develop on a large scale the possibilities of the Sunderbans and other coastal fisheries of Bengal.

The Spawning of the Hilsa.

It is alleged that the hilsa of Bengal (the Indian shad) is less abundant than formerly, and several efforts were made to locate its spawning grounds, presumably with a view of attempting to increase the supply by artificial propagation if that were found to be practicable. Meanwhile it should be noted that, in the neighbouring Government of Madras, the Conservator of Fisheries (Mr. H. C. Wilson) had made and published certain observations* on the spawning of the hilsa in the Coleroon and Cauvery rivers during the monsoon period of 1908. These observations were made at an anicut where the fish were "held up" on their way to the spawning grounds from the sea. These ripe fish were, therefore, not obtained on the natural spawning grounds. The diameters of the ripe eggs are not given. The spawning places and habits of the American shad (*Clupea sapidissima*) are now well known, and artificial hatching of this fish is extensively practised in the United States. Nothing is known of the details of the spawning of the European shad (*Clupea alosa* and *C. finta*). In Bengal it appears that the hilsa move up the rivers in the rainy season, and down towards the sea on their return journey from December to February. As they are full of "roe" when they move up, and are "spent" when they return, it follows they are anadromous—*i.e.*, spawn in the rivers. Wherever possible, adult hilsa were examined in 1909, and a careful search was made along the banks of the rivers with a fine-meshed net for the fry or larvæ. Specimens of the adult fish were purchased in the Calcutta markets, and subsequently visits were made to Sara Ghat, Rajmahal, Khulna, Bagherhat, Monghyr, and Kooshtea, in the order named. At each of these places adult hilsa were examined. No ripe females were discovered, but ripe males were examined at Rajmahal, Monghyr, and Kooshtea. At Monghyr a spent female was obtained on September 23rd; a single specimen of the fry of hilsa was also obtained at this locality. It was six centimetres in length. So that it appears as if the hilsa spawned at any rate above

* See Government of Madras. Revenue Department. G.O. No. 1219. May 5th, 1909. Artificial propagation of the hilsa in the Coleroon.

Monghyr. Reports of the young of hilsa should be verified by careful examination of specimens, as it is easy for an unpractised hand to mistake these for quite another species (*Clupea chapra*). Unfortunately, owing to circumstances over which I had no control, the investigation into the spawning habits of this interesting and valuable species was suspended at a time when it appeared probable, or, at any rate, possible, that its spawning grounds would be located.

The Culture of Carp.

The culture of the Indian species of carp, such as the catla and rahu, was attempted by the Fishery Department. A station was established at Barh, at a considerable distance from Calcutta, where the water-supply was obviously not as abundant as in Lower Bengal. Subsequently a station was started near Calcutta. Considerable sums were expended in excavating a tank or tanks at Barh, and pumping had also to be provided for. The net result was that no water could be supplied for the carp to live in, much less breed in.

A proposal to introduce legislation to prevent the sale or capture of the young of carp below a specified size was introduced to the Fishery Board by the Commissioner of Fisheries, but, as it was unanimously opposed, it was rejected.

The Establishment of a Permanent Department of Fisheries.

The future administration of the fisheries of Bengal was naturally one of the most important questions to which Sir Krishna Gupta's attention was directed, and in the thirteenth section of his second report to Government his recommendations are set forth. Had these recommendations been adopted, with an efficient permanent official to see them properly carried out, there can be no doubt that by now Bengal would have a Fisheries Department which would serve as a model for the rest of India. Presumably the consideration of the fisheries of India as a whole was outside Sir Krishna Gupta's terms of reference; otherwise it is certain that his scheme would have been of even greater effect if applied to India as a whole and not restricted to the Province of Bengal.

Practically every civilised country with a seaboard has a department for the organisation, development, and control of the fisheries, and some nations spend large sums annually on these matters. In the British Islands the value of the fish when first landed cannot be less than eleven million pounds sterling per annum.* and by the time it has reached the inland markets its value is considerably enhanced. As a matter of fact, fish is practically the only foodstuff now exported from these islands. We find in England, Scotland, and Ireland permanent central organisations with large powers entrusted with the duty of supervising both sea and inland fisheries. The organisation in Scotland, the Scottish Fishery Board, seems to have appealed to Sir Krishna Gupta, and he advised a board on similar lines for Bengal. With the sole substitution of India for Bengal, I am heartily in agreement with this recommendation. What is wanted is a central organisation similar in plan, but naturally on a smaller scale, to the Geological Survey of India. In the case of the fisheries, this department should be placed in charge of a permanent official, who should have an expert knowledge of fish and fisheries, and who should report to a small central board. Such a board should consist of five members representing the maritime provinces—Madras, Bombay, Bengal, Eastern Bengal and Assam, and Burma—one representative of the remaining provincial governments, and should meet under the chairmanship of an official representing the supreme Government. The duties of the board would consist mainly in the preparation of annual budgets and in the receiving and discussing, and, where advisable, the adopting of suggestions made by their expert official. The official—who might rank as an inspector-general—should be allowed a wide margin of freedom of action. It is only reasonable that Government, through their Board, should decide as to how much money they can devote from year to year for the improvement of the fisheries, but it is unreasonable to bring out to India an expert, and then hinder him at every turn.

It would be the duty of the Fishery Department, in the first place, to collect and publish statistical and other information relative to the present position of the fisheries of India, on the lines of the admirable reports which already exist for the Province of Bengal * and Eastern Bengal and Assam.†

Where it can be clearly shown that local fisheries have declined in recent years, the cause of the decline should be investigated and remedial measures proposed, and, if found practicable, put into operation.

A revision of the volumes on "Fish" in the

* In 1909, the last year for which official statistics are available, it was £11,012,568.

† Report on the Fisheries of Eastern Bengal and Assam. By K. C. De. Shillong. 1910.

Hosted by Google

"Fauna of India," prepared by the late Dr. Francis Day, is urgently needed, and this work could only be properly undertaken by such a department as I have indicated, working in conjunction with the staff of the Indian Museum at Calcutta. No single individual could now perform this work unassisted; it is rather a matter for a small group of expert systematists.

The training of his subordinate staff should also be one of the first duties of the permanent head of the department. As Sir K. G. Gupta says: "It would also be desirable to send young men to Europe and America to study fishery matters under competent teachers." A very commendable object, but only after a fairly comprehensive preliminary training in India, and always provided the students set out with a definite programme of work, to which they should be expected strictly to adhere. It is useless to send students abroad unless they are fully conversant with the local conditions in India, with the families of fish and their European or American relatives. Otherwise, how is the student to devote his attention to those subjects which are likely to be of practical assistance to him when he returns to India to take up his vocation? The overlapping that must ensue if any extended scheme of investigation is undertaken by a provincial Government is well illustrated by what happened in the case of Bengal. The marine investigations—which were financed by Bengal—were carried on quite as much off the coasts of the three neighbouring provinces of Madras, Eastern Bengal and Assam, and Burma, as they were off the coasts of Bengal and Orissa. Similarly, the solution of the problem of the spawning grounds of the hilsa is as important to Eastern Bengal and Assam, Madras and the United Provinces, as it is to Bengal. At the present moment you have isolated investigations proceeding in various provinces, and apparently without any attempt at co-ordination. It would be as reasonable for each province to have its own Geological Survey. The collection of statistical information relating to Indian fisheries is also a desideratum.

In conclusion, one can only say that it must be obvious even to any one who has lived a very short time in India that the fisheries of India are neglected, and it is the duty of the Government to take stock of an asset of considerable value, and further to encourage in every way in its power the development of a natural source of food supply, the potentialities of which are enormous.

APPENDIX I.

The dates of the "Golden Crown's" voyages and the localities visited are summarised below:—

No. of Voyage.	Date.	Locality.
1.	June 13th to 23rd, 1908	Pilot's Ridge and Balasore Roads.
2.	July 6th to 13th, 1908	Near Elephant Point, Arakan Coast.
3.	July 31st to August 5th, 1908	Off False Point, Orissa Coast.
4.	August 19th to 22nd, 1908	Off Pilot's Ridge Light Vessel.
5.	August 24th to September 3rd, 1908	Arakan Coast.
6.	September 13th to 19th, 1908	Arakan and Orissa Coasts.
7.	September 24th to 27th, 1908	Orissa Coast.
8.	October 1st to 5th, 1908	Orissa Coast, between Konarak and Puri.
9.	October 11th to 15th, 1908	Orissa Coast, between False Point and Konarak.
10.	October 22nd to 29th, 1908	Orissa Coast, between False Point and Konarak.
11.	November 11th to 18th, 1908	Arakan Coast.
12.	November 21st to December 1st, 1908	Orissa Coast, off Konarak.
13.	December 4th to 13th, 1908	Orissa Coast, between Konarak and Puri.
14.	December 17th to 22nd, 1908	Near Mutlah Light Vessel.
15.	December 30th, 1908, to January 7th, 1909	Arakan and Orissa Coasts.
16.	January 11th to 19th, 1909	Off Eastern Channel, entrance to River Hooghly.
17.	January 23rd to 29th, 1909	Off Eastern Channel, entrance to River Hooghly.
18.	February 9th to 15th, 1909	Off Eastern Channel, entrance to River Hooghly.
19.	February 19th to 27th, 1909	Orissa and Madras Coasts, Konarak to Gopalpur.
20.	March 5th to 15th, 1909	Orissa and Madras Coasts, down to Baruva.
21.	March 30th to April 7th, 1909	Ganjam Coast.
22.	April 15th to 24th, 1909	Orissa Coast.
23.	September 6th to 16th, 1909	Orissa and Ganjam Coasts.
24.	September 20th to October 2nd, 1909	Mainly off Ganjam Coast.
25.	October 13th to 25th, 1909	Ganjam Coast, down to Calingapatam.
26.	November 10th to 18th, 1909	Arakan Coast.
27.	November 24th to December 3rd, 1909	Off Konarak. Pilot's Ridge and Eastern Channel.
28.	December 9th to 17th, 1909	Off Puri. Ganjam Coast and Eastern Channel.

APPENDIX III.

Fishing "Log" of Launch "Ila."

The route taken by the "Ila" is, as briefly as possible, recorded below, together with the places at which fishing operations were carried out, the nature of the net used, and the kind of fish caught, if any:—

Date.	Route.	Fishing at	By	Fish caught.
	First voyage, 24-Parganas and Khulna Districts.			
August 20th	Prinsep's Ghat to Mud Point.			
,, 21st	Mud Point to Bosondheer abad.	Bosondheer abad	Drift-nets	Nil.
,, 22nd	Bosondheer abad *viâ* Kaliganj to Chandkhali.	Burra Kaligatchia.	Shrimp-trawl	Topsee, bummaloes, shrimps and prawns.
		Nubaspore near Kaliganj.	Ditto	Ditto.
		Culpoottooa River.	Ditto	Prawns, few small fish.
		Ditto, second haul.	Ditto	Bholas, siluroids, bummaloes, gobies.
,, 23rd	Chandkhali to Khulna	Seepsah River	Ditto	Few shrimps.
		Khulna	Drift-nets	Nil. Had to haul immediately to avoid fouling native nets.
,, 24th	Khulna to Creek near Rupsah River.	Rupsah River	Shrimp-trawl	Nil. Net got foul with propeller and badly torn.
,, 25th	Above Creek to Morrelganj and then to Bagherhat.	Morrelganj	Ditto	Soles (cynoglossus), bholas and siluroids.
		Bagerhat	Drift-nets	Bholas.
,, 26th	Bagherhat to Pussur River (Creek near Chandpai).	Ditto	Ditto	Bhekti.
		Creek near Chandpai.	Ditto	Nil; net badly torn.
,, 27th	Chandpai to Khulna	Chandpai	Ditto	Fensa.
,, 28th	Khulna to Botiaghatta	. . . .	. . . . . .	No fishing. Coaling.
,, 29th	Botiaghatta to Bosondheer abad. Bosondheer to Calcutta *viâ* Mutlah and Canal.	Bosondheer abad	Drift-nets	Siluroids.
	Second voyage, entirely in 24-Parganas District.			
November 10th	Prinsep's Ghat to Chennia	Chennia	Drift-nets	Bhekti.
,, 11th	Remained at Chennia	Ditto	Ditto	Good haul. Siluroids, bhekti, sele, cuja bhekti, with *Chirocentrus dorab*, and *Scatophagus argus*.
,, 12th	Chennia to Fraserganj	Ditto	Shrimp-trawl	Good haul of shrimps, prawns, and bummaloes.
		Fraserganj	Drift-net	Large mullets, siluroids.
,, 13th	Fraserganj	Ditto	Shrimp-trawl	Few shrimps and small fish. Had to haul soon owing to strong wind and tide.
	Ditto	Ditto	Drift-net	In creek. Siluroids.

APPENDIX III.—*continued.*

Date.	Route.	Fishing at	By	Fish caught.
		Second voyage, entirely in 24-Parganas District—continued.		
November 14th . .	Fraserganj to Kankondighee (for coal).	Jhobar Deol (near Kankondighee).	Shrimp-trawl	Shrimps and small fish; moderate haul.
		Kankondighee .	Drift-nets .	Sole, bhekti, clupeoids, sharks.
„ 15th .	Kankondighee to Matla	Matla . . .	Drift-nets .	Nil. Very strong current.
„ 16th .	Matla to Basanti F. S. .	Matla River . .	Shrimp-trawl	Good haul. Shrimps, bummaloes, pangash.
		Hooghly nullah	Ditto . .	Moderate. Shrimps, bummaloes, pangash.
		Basanti . . .	Drift-nets .	Sole (2 feet 2 inches), goby (1 foot 5 inches).
„ 17th .	Basanti F. S. to Guasuba River (Creek below Lot. 156).	Matla River . .	Shrimp-trawl	Moderate haul. Shrimps and bummaloes.
		Guasuba River .	Ditto . .	Moderate haul. Shrimps and bummaloes.
		Ditto . . .	Drift-nets .	Sole, cuja bhekti.
„ 18th .	Guasuba River to Kankondighee (for coal).	Kaikal Maree .	Shrimp-trawl	A few shrimps and bummaloes.
		Kankondighee .	Drift-nets .	No fish.
„ 19th .	Kankondighee to Ellplot	Ditto . . .	Ditto . .	Do.
		Creek near Ellplot.	Shrimp-trawl	Moderate haul of shrimps and bummaloes, etc.
		Ditto . . .	Drift-nets .	Siluroids and one cuja bhetki.
„ 20th .	Ellplot to Fulta . . .	Creek near Ellplot.	Drift-nets	Bhekti, cuja bhekti and
	Ditto	Ditto . .	Ditto .	*Lutjanus johnii* and *Toxotes jaculator.*
„ 21st .	Fulta to Calcutta . .	Channel Creek .	Shrimp-trawl	Few shrimps and bummaloes.
		Third voyage, 24-Parganas and Khulna Districts.		
December 5th .	Prinsep's Ghat to Mud Point.	. . . . . .	. . . . .	Unsettled weather, heavy rain, disturbed sea.
„ 6th .	Mud Point to Sonadigheee.	Sattermukhee River.	Fish-trawl .	One large sole and a few *Trygon* and *Scatophagus.*
		Sonadighee . .	Drift-nets .	Siluroids.
„ 7th .	Sonadighee to Basanti F. S.	Khultollee Creek	Fish-trawl .	Net badly torn. Foot-rope fouled with anchor; no fish.
		Basanti F. S. .	Drift-nets .	Only one globe fish (*Tetrodon fluviatilis*).
„ 8th .	Basanti F. S. to Seepsah River (Khulna district).	Kaliganj . . .	Fish-trawl .	Net badly torn; no fish.
		Near Kaliganj .	Shrimp-trawl	Towed at surface. Shrimps, small fish, such as *Barbus* and *Engraulis.*
		Menus River .	Ditto . .	Towed at surface. Shrimps, fensa, pangash, *Ambasis*, *Tetrodon.*
		Seepsah River .	Ditto . .	Few shrimps and small fish.
„ 9th .	Seepsah River to Khulna for coal, and then to Shelah F. S.	Creek near Shelah.	Ditto . .	Good catch of shrimps, also bholas, soles, *Scatophagus* and *Tetrodon.*

Hosted by Google

APPENDIX III.—*continued.*

Date.	Route.	Fishing at	By	Fish caught.
Third voyage, 24-Parganas and Khulna Districts—continued.				
December 10th .	Shelah F. S. to Mirgamari River (*viâ* Pussur River).	In Mirgamari River (below plot 248).	Shrimp-trawl	Few shrimps, prawns and small fish, *Chorinemus*, pangash, *Gobius sadanundis*.
			Drift-nets .	Bummaloes, bhola, and *Trichiurus*.
„ 11th .	Mirgamari River to mouth of Bungarah River.	Bungarah River	Shrimp-trawl	Shrimps and bummaloes Moderate haul.
		Ditto . .	Fish-trawl.	Nil.
		Mouth of Bungarah River.	Shrimp-trawl	Good haul. Shrimps, prawns and bummaloes.
„ 12th .	Mouth of Bungarah River to Shelah F. S.	Shelah F. S. . .	Ditto . .	Few shrimps.
„ 13th .	Shelah F. S. to Khulna (for coal).	. . . . . .	Drift-nets .	Nil.
„ 14th .	Khulna *viâ* Kaliganj to Sorabkatti.	Sorabkatti (24-Parganas).	Ditto . .	Nil.
„ 15th .	Sorabkatti to Surajbuggi	Near Sorabkatti, 24-Parganas.	Shrimp-trawl	Net badly torn; a large tree in it. Strain caused beam to break. A few bholas, bummaloes, pangash, and other siluroids in cod end.
		Surajbuggi . .	Drift-nets .	Sole, mullet, cuja bhekti.
„ 16th .	Surajbuggi to Calcutta (*viâ* Matla).	Ditto . . .	Fish-trawl .	Nil.

DISCUSSION.

Sir K. G. Gupta, K.C.S.I., in opening the discussion, said that those who had listened to the paper need not be told that he felt very much interested in the fisheries of Bengal. He was very glad to take part in the discussion, because while he was wandering about Great Britain for the purpose of obtaining information with regard to fisheries, he came across many competent experts, amongst them the author. He then made a mental note that if an opportunity occurred he would like Dr. Jenkins to be sent out to Bengal. That opportunity was subsequently given him, and to the great benefit of the new Fishery Department of Bengal Dr. Jenkins's services were utilised, although, he was sorry to say, only for a very short time. Those who had not studied fish could have no idea of the fascination which the subject exercised over those who took an interest in it. Personally, he took to the fisheries question rather late in life. It was not until within two or three years of his retirement from the Indian Civil Service that he was called upon to take up the inquiry to which reference had been made. When the offer was made he was utterly amazed, because he knew nothing of fish. He had not even done anything with the rod and line. However, as those who had been in India knew very well, the civilians were supposed to know everything, from administering a district, dispensing justice, collecting revenue, looking after sanitation, to inspecting schools. He therefore thought it was his duty not to refuse, and thereupon he took leave and began studying the very elements of the subject. Having acquired a sort of elementary knowledge, he started on his inquiry, and having done with Bengal he was allowed an opportunity of visiting the great fishery departments of this country, the Continent, the United States, and Canada. It was surprising what a large amount of useful information could be gathered within a short time; and with the generous help of various officials in all the countries he visited he was able to get a fair insight into the working of their fishery departments. He did not pretend to have any scientific knowledge at all; his business was with the administration, to see how the fisheries in Bengal could be conserved and developed. Many false ideas were held in regard to the matter. It was very often said that Indian fishermen knew their business very well, and it was impossible to teach them anything.

Hosted by Google

The same remark used to be made with regard to the Indian peasant. When agricultural improvements were mooted, it was at once stated that the Indian peasant knew everything, and being poor he could not adopt Western or improved methods. But all those ideas had changed. There was now in India a great central Agricultural College; the Provinces had their separate colleges, and the old exploded idea that the Indian peasant could not be taught had disappeared altogether. He was in hopes that the same thing would happen with regard to the fisheries. To his mind, land and water were equally productive of human food. When he was in Bohemia he visited a very big estate of one of the princes of Hungary, and there, along with the cultivation of crops and the rearing of cattle, he found immense tanks devoted to the culture of that valuable fish, carp. The manager of the estate told him that from an acre of fish two or three times more profit was obtained than from the same amount of land grown with crops. The author had confined his paper more to the sea and estuary resources of Bengal, but in addition to these there were immense water surfaces in the rivers of lower Bengal, which could be utilised more largely for the cultivation of fish. As an example of the scientific methods of cultivation, he was told, when visiting the United States, that before 1877 carp was an unknown fish in America. About 1877 or 1878 the Fishery Department introduced a few dozen carp, and within a few years, with proper care and cultivation, they spread all over the country, so that that particular species of fish did not now require any further cultivation. In the City of New York alone, more than a million pounds of carp were now consumed every year. What was particularly required in Bengal was conservation and development. The present methods of catching were too destructive, and both the fishermen and the owners of private waters had yet to learn that, in order to get the full benefit of an abundant fish supply, it was necessary to conserve and develop their resources. Every civilised country had been obliged, for the sake of maintaining a proper and adequate supply, to establish close seasons, and to open hatcheries, and so on. Those were methods of very great importance, and if the fresh waters of India were not to be denuded of fish, recourse must be had to those measures. It was easy to imagine what would have become of the salmon supply in this country if a closed season had not been inaugurated, and strict regulations promulgated prohibiting capture at certain seasons of the year. There was no such regulation as yet in India. In times gone by when the population was smaller, the natural supply was, perhaps, sufficient, but now the population was increasing while the area of fresh-water fish supply was gradually diminishing. If the fresh-water fish resources of India were to be fully utilised, recourse must be had to measures that had been found so very useful and productive in other countries. So far, both the landlords and fishermen of India had not realised that point. All fishery legislation was very much resented by fishermen all over the world, because they did not know their own interests. They had to be educated; and that was one of the principal duties of a Fishery Department. He was glad to say the Fishery Department in Bengal had been put on a permanent footing, although on a very limited scale. It was to be hoped, however, that as soon as public opinion began to recognise the great importance of the subject, the activities of the department would be gradually amplified, and that full results would be obtained. With regard to sea fisheries, the author had naturally confined his paper to the results he obtained from trawling, but the sea yielded its wealth not merely by trawling but by other means of capture. The surface fish was not caught by trawls; the herrings and mackerel were caught in different ways by drift-nets. The possibilities of Indian sea fisheries with regard to surface fish had not yet been exploited. There were only two points in the paper he wished to criticise. In the first place the author stated that before his (the speaker's) report nothing had been done in regard to fishery matters in India. He did not think that was quite correct, because, apart from the labours of men like Day, Thomas, and others, within recent years his friend, Sir Frederick Nicholson, had done a great deal in Madras to develop the fisheries of that Province. It was due to Sir Frederick to say that in his quiet way he had been steadily working to develop the fisheries of Madras, and had succeeded in a large measure. In the second place, he did not agree with the author that one fishery board should be established for the whole of India. India was a very vast country, and if a central board were established, how would it be possible to get the representatives of the different Provinces together? In the present days of decentralisation one must not talk of a central board at all. Many of the Inspector-Generalships that were created not many years ago were disappearing. Some had already gone, others were trembling in the balance; so that if anyone suggested a central board of the kind mentioned, the idea would be entirely discounted. Personally, he thought that, after all, it would be best to have provincial boards. The circumstances of each Province were so different, especially with regard to fishery matters, that it would not be of any advantage to have one board controlling the whole country. Of course the time would come, as it had in the United States, when there would be a central office regulating fishery matters all over the country, while each of the several Provinces had their separate Fishery Department, but that day was far distant. In the meantime they ought to be satisfied if each Province which had large fresh-water fisheries as well as sea fisheries had a separate department working properly and adequately. He desired, in conclusion, to express his high appreciation of the work done by the author, and of his very excellent paper, which had been illustrated by such beautiful slides.

Hosted by Google

SIR JAMES BOURDILLON, K.C.S.I., said that many of those present who lived in Calcutta some years ago would remember the energetic gentleman who edited the *Planters' Gazette*, Mr. Harry Abbott, and it might be within their recollection that he started a company for supplying Calcutta with fresh fish, and to search after the mine of treasure to which the author had referred. It would be of great interest if Dr. Jenkins could state what the result of that venture was.

THE CHAIRMAN, in proposing a cordial vote of thanks to the author for his exceedingly interesting and valuable paper, said he was sure everyone recognised the fact that Dr. Jenkins's work was neither easy nor light. Anyone who had travelled through the Bay of Bengal during a north-east monsoon would know that a voyage in a trawler at such a time was anything but a pleasant experience. He was also sure that those present sympathised with the author in the difficulties he experienced in obtaining a proper vessel in which to conduct his experiments. Personally, he was ignorant of the reasons which led to the alterations in the trawler which was eventually placed at his disposal, but he could quite understand that they might not have been intentional or even carelessly caused, but that they were the result of want of means and ability. Such things did interfere seriously with the desire of experts to get on with their work. He made that plea because, being an old official, he knew that one was sometimes accused of obstruction when there was no such feeling in one's mind. He fully agreed with the author's statement that the whole subject of deep-sea and estuarial fishing turned on the question of transport. From that point of view Dr. Jenkins made the very valuable suggestion that if anything was to be done in the way of establishing a deep-sea fishing company, Diamond Harbour and not Calcutta must be the central point for the work. The reasons the author gave for that opinion appealed very strongly indeed to anyone who knew the geography and the local circumstances. The author had given a great amount of valuable information with regard to the method of fishing adopted, and the amount of fish which might be obtained out of the sea and also out of the Sunderbans, but he had not said anything about the inland fishing. Anybody who had been on the Megna and Pudda in the rains knew that an enormous number of boats fished daily, and caught fish by the ton. He thought he was also right in saying that for several months of the year the Eastern Bengal Railway ran a daily fish-train from Goalundo down to Calcutta, and that Calcutta was very largely supplied with fish, during the hilsa season at all events, from the rivers to the north of it. Fishing went on all the way up to Monghyr, and further up still, the Ganges being covered with little fishing-boats at night. That was a source of supply to the country, and how far that would come into competition with the larger sources of supply to which the author had referred was a point which ought to be considered. Another point touched upon by the author was the salting of the fish. Dr. Jenkins spoke of the necessity of salt free of duty being supplied for the fish industry, a point which, personally, he quite understood and appreciated. As Dr. Jenkins stated, the whole question of fresh-water fish supply depended upon transport, and the difficulty was overcome if the fish could be preserved. Some years ago, just before he left India, an experiment was tried, on the Madras side, of giving a fish company salt free of duty in order to try to preserve fish. It would be of great interest if the author could state how that project eventuated. He knew a great deal of difficulty was experienced in ensuring that the salt which was given for those fish purposes should not be used in ordinary business transactions. He did not see how it was possible to overcome that difficulty, but even if that was the case it mattered very little. It was perfectly possible to arrange that the loss would be small, and it was a subject that need not be considered in comparison with the additional food supply which would thereby be obtained. Sir Krishna Gupta had touched upon the possibility of carrying out the author's suggestion for a co-ordinated authority all over India to control, teach, and exploit fisheries. Personally, he thought it might be possible to combine the author's and Sir Krishna Gupta's points together, namely, to have provincial control with provincial superintendents for each Province, who might be brought together to sit as a board two or three times a year. That would probably to a certain extent meet the objection that had been raised. He admitted, however, that the financial difficulties which Sir Krishna referred to were paramount at a time when some of the Inspectors-General were being abolished and some of them were hanging by the hairs of their heads. On the one side scientific and even army work was being cut down for the sake of economy, while on the other side they were threatened with an enormous expenditure on new capitals and new provinces; and it was not very likely that a small thing of the kind referred to, although it did add largely to the food supply of the million, and made two blades of grass grow where one grew before, would be very easily granted.

SIR GEORGE BIRDWOOD, K.C.I.E., C.S.I., in seconding the vote of thanks, said:—His title to take a part in the discussion on the most instructive and most attractive paper with which Dr. Travis Jenkins had favoured them was,—that while in Bombay he had taken a great interest in the fisher-folk, Christians and Hindus, about Bombay, and along the coast of the Concans down to Savantvari, and the River Rachol in the Goa territory; that while serving for over thirty years in the India Office he had kept in touch with questions relating to the Indian fisheries, "the most fishful of all in the world" [as Solinus says of those (sardines, etc.) of Sicily], so far as they came

Hosted by Google

before him officially; and that directly he left the India Office he was asked to advise some gentlemen who were contemplating the formation of a syndicate for the express purpose of organising a company for the development of the miraculously prolific fisheries of the Bay of Bengal and the Sunderbans, which alone are capable of supplying cured fish of over one hundred edible, and of these from ten to twelve greedily comestible, species. He wished that his son, Mr. Frank Birdwood, when invited by the Chairman to speak on Dr. Travis Jenkins's paper, had done so, for what he would have had to say of the projected syndicate and company would have been most suggestive, and, in spite of the abandonment of their tentative adventure, most inspiring. The Government of India, both in London and at Calcutta, were most considerate, and indeed helpful; but the difficulties then presented by the Salt Tax, which may be said to have now practically disappeared, and by the land regulations, prevented his friends proceeding further with their enterprise. It was some time subsequent to this period that he became acquainted with Sir Krishna Govinda Gupta's masterly report, of which they had now all heard so much for themselves from Dr. Travis Jenkins; and began to hear of Dr. Travis Jenkins's own good and truly redoubtable researches, with the "Golden Crown," in the Bay of Bengal, which were sure to bear the very best good fruit, and that in the immediate future. The Government of India were to-day more ready than ever to meet stable and honest adventurers with regard to modifications of the Salt Tax for the single-eyed purposes of fish-curing; and they might well remove it altogether, for from the physiological and medical points of view, it was a sheer iniquity; and they might readily lift off the burden of it from the shoulders of the people of India if they would but hold on to the opium tax; this tax being wholly paid by the people of China, and opium, from a physiological and medical point of view, being an essential dietary "adjuvant" to the due nourishment and health of all hard-working vegetarians, like the 200,000,000 agriculturists of India and Farther India. In any case, either the Salt Tax should be modified, and to abolition, at least for the fisher-folk of India, or the Government should be prepared and eager to assist alike Indian and English capitalists who might be found willing to reorganise the fisheries of India on a wider, and more thorough, and more productive basis; which could not be attempted by conscientious private capitalists without State aid, in some shape or other, at the start. Give them this assistance, and the harvest of the Indian Ocean would embrace the whole wide world for its market—its "Forum piscarium." These were the conclusions he (Sir George) had come to after his small, but well-manifest experience as an interloping "City man," and all that he had heard that evening from Dr. Travis Jenkins, and Sir Krishna Govinda Gupta confirmed him in them.

But a further "stone of stumbling" in the adventure was the way in which the English fisheries' experts, and his own adventuring friends, industrial and commercial, and the State officials in London and in Calcutta, would persist in looking at the problem before them from the English point of view, and not only the English officials, but the very Indian ones, as in the instance here, and this instant evening, of Sir Krishna Govinda Gupta. This was the very "rock of offence," this incorrigible English egotistry of ours, that had prevented the "Burma Ruby Mines" from ever paying an adequate dividend on their capital; as he (Sir George) had said would be the case some fifteen years ago in that very room. English experts were sent out, and English machinery, and the whole adventure was schemed on the basis of English experience: whereas the working of the rich ruby mines of Burma by the Burmese themselves ought first to have been studied by our experts on the spot, and the confidence of the native miners in the Company thus secured; when at once we would have been able to introduce improved methods, if required, for increasing the output of rubies, and to-day be reaping the rich reward of our sagacity, and superior [scientific] skill. But how should Englishmen be blamed for their industrial egotism when we found an Indian official, of the highest ability, and who had attained to the highest positions in the service of the Imperial Government of India, telling us here that on being appointed to the sphere of duties, detailed in his notable report, which marked the opening of a new and most hopeful era in the history of the Indian fisheries,—telling us that instead of first studying them all round the coasts of India, he at once went off to study the fisheries of England, and Scotland, and Wales, and Canada, and the United States,—anywhere, wherever we are all English, and Sir Krishna Govinda Gupta the most English of us all! It made him (Sir George Birdwood) feel as if he was the only pristine Hindu left, all marooned in a bitterly cold world! It was, indeed, all a-piece with the attitude taken up by us toward Indian literature and art until about thirty years ago, and still continued toward Indian education, and agriculture, and sociology, and religion. Steam trawlers were hopeless in the present circumstances of the Indian fisheries, and when they were introduced, they must be worked by the native fisher-folk themselves; the finest, healthiest, heartiest, and most industrious and strenuous in the world. About Bombay they were hard drinkers, but always overflowing with happiness while at their ceaseless labours. In their long, narrow "dug-outs," with bare room in them for four of these "wave-wandering rowers and riflers of the deep"—[*Fluctivagos nautas scrutatoresque profundi*]—the fire in the prow was always alight; and the curry pot was never off it; and for every long-handled ladle of fish eaten out of it, another of fresh fish, with a pinch of cayenne pepper, was stirred into it, and no daintier dish was ever devised to tempt the appetite, and support the strength of hard-working men. With Dr. Bhau-

Hosted by Google

Daji, he (Sir George) had spent days and nights with these stalwart, merry-hearted men in Bombay Harbour, and off Goa; and when at night the moon rose over the sea, they would ever begin some antiphonal chaunt, each boat of the tossing flotilla answering to, and being answered by, every other. It was most romantic, and devotionally soothing, and most delectable. Nearly always the words of the songs were sacred; but once, on a memorable occasion, which must be another story, though the name of almost every Saint in our Christian Calendar was borne to his ears, they were most profanely used, in what proved to be a recitation of "The Temptations of St. Anthony," on the model of the operatic list of Don Juan's misdeeds. Sir Krishna Govinda Gupta said that to improve the condition of these people, or rather to exploit their lives and labours more profitably to the country, we must add English Schools, and Colleges, and Universities, to English Schools and Colleges, and Universities, over all India. And what would be the effect of that, but at the last to ruin the lives, through ruining the livelihood, of this happy industrial Indian community, in exactly the same way as we had already destroyed the labours and the happiness of the indigenous literary and professional classes in India; and to extend the "unrest in India," which now infected only a decimal point of the population, throughout the whole of that vast extended tropical and sub-tropical peninsula, with its teeming population of over 300,000,000, the most patient, the most industrious, the most religious, and the most joyous in the world, if but left restfully and peacefully to work out their own material, and moral, and spiritual prosperity, and happiness, and salvation.

There was no limit to the potential wealth of India in fish—in the pools and ponds, in the rivers, and in the sea. The sacred fish [*cf.* Derceto, and κῆτος, "cetus," and (?) Cette, Cettinge] in the temple tanks of the Concans were packed as close as herrings in a barrel, but all alive, and ceaselessly tumbling over one another, the patriarch of them all being at times distinguished by some ornament fastened to his head or tail; their sacredness being due to the hierophallic Hindu conceptions of their superabounding fecundity; which was indeed the ultimate explanation of the early symbolisation of the Saviour by a fish, although the proximate explanation given at the time when such prehistoric conceptions had been forgotten, was that the Greek word Ἰχθύς was composed of the initial letters of the Greek for:—"Jesus the Christ, God's Son, (our) Saviour." Even in the Victoria Garden which he had laid out in Bombay, at once, as the south-west monsoon burst over them, the deeper gutters became alive with small fish (and frogs), and he used to sweep them up with a winnowing fan, and curry them, whenever required for that purpose, from June to September. All adown the coast of the Concans to Goa, the limit of his voyages, the Hindus eat fish—even the Brahmans, such as Dr. Bhau-Daji—and it was only congers, and other scaleless fish, nor Muslims, nor Hindus [*cf.* Levit. xi. 9–12, and Deut. xiv. 9–10] would eat. But it was equally to the export of cured fish that those who would adventure on the commercial development of the fisheries of India should fixedly look for profitable returns, and in the end the most profitable. It was all nonsense discriminating between cold-water fisheries, as of the North Sea, and the North Atlantic, and warm-water fisheries, as of the Indian Ocean. From the earliest history of the East and of the commerce of the West with the East, India was included among the countries of "the Ichthyophagi,"—Farther India, and India, and Gedrosia [Mekran], and the whole coast of Arabia Felix,—an illuminating fact that should never be forgotten by anyone practically and responsibly interested in this inquiry. Again, the commerce of Europe with the East Indies began in consequence of the pepper, and other spices of India, and the Indian Archipelago, being required for the curing of fish, first of the Mediterranean, and later on of the Atlantic and North Sea; and the whole of our Indian Empire —the most glorious jewel of the Imperial Crown of Great Britain and Ireland—was from the very first latent in these pepper grains, and other spices. It was because the competing Dutch of that day, who connote the competing Germans of this day, raised the price of pepper, by a fraction, against us, that we fitted out "The First Voyage" of our first East India Company, to import pepper, and every other Indian spice, on our own behalf: the "Red Dragon," and her companion ships, starting from the Thames the very week that Akbar, the greatest of "the Great Mogols," lay sick in India, and further sickened by the gloomiest forebodings of evils to come on what was to prove his death-bed. Well, if India only once succeeded in developing her fisheries, she would be found in due time exporting cured fish, as well as pepper and her other spices, into Europe and America; when much of the rivalry between England and Germany in the North Sea, and of England with France, and the United States of America, over the Newfoundland Cod Fishery, would at once begin to lower in temperature,—to something near freezing-point, a consummation devoutly to be hoped for, and obviously latent in the solution of this stirring problem of the development of our Indian fisheries; and from such ports as Kurrachee, and Bombay, and Madras and Singapore. Whenever the solution came, it would largely be due to the good work done by Sir Krishna Govinda Gupta and Dr. Travis Jenkins; and he most cordially seconded the vote of thanks to Dr. Travis Jenkins moved by the Chairman.

The resolution of thanks was then put, and carried unanimously.

Dr. Travis Jenkins, in reply, said he was sorry that he had omitted any reference to Sir Frederick Nicholson, but, as a matter of fact, his paper was entitled "The Fisheries of Bengal," and with the

Hosted by Google

limited space at his disposal he purposely omitted referring to other parts of India. He did not see anything of Sir Frederick's work, but he read his reports, and considered they were very excellent ones. In reply to Sir Krishna Gupta, he dated his observations from the time when Sir Krishna started his work. He purposely omitted any reference to Dr. Day, because he had been dealing with recent investigations into fishery questions. In reply to Sir James Bourdillon, a company was started in Calcutta some years ago to exploit the Sunderbans and the Bay, but they went about their work in the wrong way, and the company failed. The same thing happened just before he arrived at Lake Chilka, some Norwegian fishermen having been there and tried to fish without success. His own opinion was that the solution of the difficulty lay in the transport of fresh fish in ice from those localities to Calcutta. If the fish could be bought from the local fishermen cheaper than it could be caught in any other way, what was the use of introducing European methods of fishing? With regard to the question of preserving the fish, he thought, personally, that transport in ice was far better than any other method of preserving. He was sorry the Chairman had taken such pessimistic views of the suggestions made for the development of the fisheries of India, and he trusted he might be pardoned for hoping that they would turn out to be falsified by events.

THE MINING INDUSTRIES OF TURKEY.

Although in the absence of railways it is impossible to take proper advantage of Turkey's mineral wealth except on the sea coast, the mining industry is by no means a negligible factor in the economic life of the country. Salt is a State monopoly, the receipts from the internal trade in the fiscal year 1909–10 aggregating over a million sterling. The export trade amounted to £88,000. While the bulk of the salt produced is consumed at home, some of it is exported to India and Bulgaria. In the Jordan Valley, a French company is beginning to exploit the phosphate of lime deposits, having obtained a concession for that purpose from the Turkish Government, involving a loan to the latter for railway extensions and for the construction of a harbour at Haifa. The minimum annual output is placed at 100,000 tons. The Syrian bitumen beds in the Dead Sea region, at the headwaters of the Jordan, and in the vicinity of Antioch, are not being worked regularly, but these, in the opinion of the American Consul-General at Constantinople, may create a flourishing industry. The mines of an Anglo-French concern operating in the Mersine district in 1910 produced 24,000 tons of iron ore. The same company has opened a zinc mine in the neighbourhood, which in 1910 produced 400 tons of ore, and was expected to yield about 2,000 tons in 1911. Among mines in Turkey which have already reached a certain stage of development, may be mentioned the chrome mines near Alexandretta (output unknown); Mersine, 1,800 tons in 1910; Smyrna, 14,000 tons; and Salonica, 380 tons. The State works certain mines throughout the country, among which are the copper mines at Arghani near Biarbekir. The latter are likely to be leased to a private company for exploitation on a large scale. Coal is already being mined somewhat extensively at Heraclea by French concessionaires, whose contract expires in 1946. The output in 1909 was 654,118 tons, an increase over the previous year of about 100,000 tons. Official permits have been granted for 215 mines, sixty-nine of which are being worked. It may be said, generally, that Turkey is exceedingly rich in minerals, and that its mineral wealth has hardly yet been touched. The mining law of 1906 grants facilities which should act as an incentive to the development of new mining enterprises.

THE ALMOND TRADE IN PROVENCE.

Almonds are grown in many parts of the south of France, but those of Provence are amongst the best, and are considered superior to those of Spain, Turkey and other countries. They are gathered as soon as the outer shell is sufficiently dry to be removed easily. They are then placed on trays, and exposed to dry in the sun for about ten days; they are taken in at night. As soon as the shells appear to be sufficiently dry and the almonds become lighter, they are removed to the warehouse, and packed in boxes rather than in sacks. The shells are bleached by placing the almonds on trays in hermetically-closed rooms and exposing them to the fumes of burning sulphur.

Almonds are usually classed, as those with hard shells (*amandes ordinaires*); those with less hard shells (*amandes demi-fines*), and the soft-shelled varieties (*amandes fines*), the shells of which are easily broken with the fingers.

The shells of the *demi-fine* quality are sometimes softened, by steaming, in order to remove the outer layer of the shell, and then they are sold as the best quality.

Shelled almonds (*amandes cassées*) are chiefly in demand by confectioners (650 to 700 almonds to the kilogram = 290 to 315 to the pound). The principal market for this fruit is the town of Aix, near Marseilles; about 2,000 tons, to the value of eight million francs (£320,000), being exported annually from the south of France, principally to Paris, England, Germany, Austria and Russia.

The soft-skinned kinds are liable to attacks from a small moth, the *Paralipsa gulasis*, which causes considerable damage when the almonds are stored for any length of time. For this reason, the walls and woodwork of the warehouses should be carefully whitewashed, and kept at a low temperature.

ARTS AND CRAFTS.

Silversmiths' Work.—There is, perhaps, no craft on which the Arts and Crafts movement has had so great and, in the main, so satisfactory an influence as that of silversmithing. Of course, there was a time when every little exhibition of Arts and Crafts was flooded with immature and amateurish work in silver, and there is still a good deal of jewellery and even of larger silverwork to be seen which makes one feel inclined to wish, for the moment at least, that craftwork did not exist, and long for a well, if somewhat mechanically, finished piece of work. Again, as regards jewellery, a conventional craft style has arisen which is quite as marked as, and not much more original than, that of the machine-made work. Not only is it quite possible to go round some exhibitions and tell almost at a glance under what master, or at what school the exhibitors have studied, but it is easy to go further and trace a very strong family likeness in nine-tenths of the objects on view. But, when all this has been admitted, the fact remains that at the present time there are quite a number of silversmiths who are also artists — perhaps it would be more accurate to say artists who are also craftsmen, for in England there is a tendency to begin from the side of art, just as in France the starting point is generally technique. Since silverwork and jewellery are, for those who can afford them, the most fitting kind of presents, it is by no means surprising that some at least of the artistic silversmiths make an effort to have a good supply of work at Christmas time, and to show it either in their own studios or in one of the smaller galleries.

Messrs. Ramsden and Carr and Mr. Alexander Fisher.—There have been two noteworthy shows of metalwork this season—that of Messrs. Ramsden and Carr, at St. Dunstan's Studio, Seymour Place, South Kensington, S.W., and that of Mr. Alexander Fisher, at the Leicester Galleries. Messrs. Ramsden and Carr's show was somewhat different from their usual winter exhibitions, as much of their larger work this year has been commissioned for the colonies and other places abroad, and they found themselves, therefore, more dependent than usual on smaller things. In one way this was no drawback, for it left their visitors more leisure to see how successful they are in making ordinary objects of common use, such as toast-racks, table-napkin rings, silver cups, boxes, forks and spoons, and the like—real works of art. However, the interest of large work was not lacking, as there was a tall two-handled cup and cover ornamented with bas-reliefs to be presented to a mining engineer, and also several large caskets and a very elaborate tobacco-box with decorations illustrating Chaucer's "Man of Law's Tale," whilst photographs of other works were on view. The reproduction of the brass lectern, formed by a bold and severe heraldic eagle, was perhaps the most noteworthy; but that of the large boat-shaped centrepiece and candelabra, made for the Jockey Club of Mexico, was full of vigour and by no means wanting in interest. The impressions of the episcopal seals of the Bishops of Winchester and Oxford were up to their makers' usual high standard in this kind of work. There was a much more attractive show of jewellery than usual: the small chains were dainty and ingenious in the extreme, and several of the pendants and other more important pieces were really beautiful.

Messrs. Ramsden and Carr's individuality is always very marked, but, like most of the best craftsmen, they are the product of the past. Their work is modern in the best sense of the term, but it is most happy, mostly truly and evidently their own, and generally most satisfactory, when it is distinctly Gothic in feeling. Mr. Fisher, on the other hand, is a modern of moderns. The expression *art nouveau* has become so much a term of opprobrium that it seems almost unkind to apply it to really good work like that shown at the Leicester Galleries, and yet it is the new art which has influenced Mr. Fisher far more profoundly than the ancient styles. We find here and there in his work, lines and curves which were considered the height of modernity some years ago; but the artist is no follower of any set style, not even the most modern, and his work as shown in Leicester Square reveals a quite unusual combination of individuality and versatility. Perhaps the most interesting piece of work is the cup, partly of silver, with a broad band of decoration in *plique à jour* enamel round the top, a carved ivory bowl and a stem built up of carefully chosen bits of *lapis lazuli* arranged facet-wise. The quality of the enamel is unusual for work of this kind, as it is semi-opaque instead of brilliantly translucent. This detracts somewhat from the beauty of the enamel itself, but is far more in harmony with the ivory bowl below it than the brighter material would have been. Of the enamel panels exhibited, the most striking is the one entitled "Until the Day Break," in which the flaming red of the angel's wings is a truly gorgeous piece of colour. The colour-scheme of the enamel decoration of the small electric bell, on the other hand, is quite beautifully delicate and tender. Amongst the larger pieces of work on view, the massive silver wine-flagon is perhaps the most satisfactory, as well as the most attractive, but the steel casket and the bronze mirror are also well worthy of notice. The jewellery is for the most part rather large and massive. This is no drawback in the case of the two morses, one of which, representing the Adoration of the Magi, is a very happy piece of work. The silver setting, again, of one of the enamel clasps, simple as it is, demonstrates that the man who made it knew what he wanted to do and did it. But, on the whole, the jewellery was the least satisfactory part of the exhibition, not so much because the things themselves were not beautiful as because they were less eminently fit for their purpose than they might have been.

Hosted by Google

Home Arts and Industries.—The winter exhibition of the Home Arts and Industries Association is always a less serious affair than their summer show, but the association is careful not to let it degenerate into a glorified bazaar. And this year one felt no desire to judge it from a lower standpoint than usual. There was, indeed, one stall which might with advantage have been omitted, but for the most part the exhibition justified itself as a legitimate collection of artistic craftwork of varying degrees of excellence. The show of metalwork was rather smaller than it has sometimes been, but the simple hammered work from Keswick was satisfactory, even when such important work as a silver altar cross was attempted. A good deal of lace was shown; Honiton, guipure and filet were all well represented, but there was little or no Buckingham lace. The Kingston-Bagpuize metal lace was for the first time applied to velvet and other materials to ornament collars, belts, and the like, and showed to much better advantage than usual. All lace is difficult to display successfully on a stall, but gold and silver lace takes even more careful arrangement than the ordinary white and cream varieties. From Langdale came some beautiful Greek lace and drawn thread work—the prettiest perhaps, that in which the stitchery was in white on a sort of unbleached coloured ground. The embroidery and appliqué work sent by the Wilton Industries was, as usual, bold and attractive—the very kind of thing which can be best executed by a village class if, and it is a very big if, the classholder has sufficient knowledge, ability and initiative to carry it through. An attractive little group of Mrs. Watts' pottery was on view, and some dainty inlaid wooden boxes and the like were shown by the Hanwell class. The best leatherwork was from Chiswick, and included bookbinding and lacquering. The hearthrugs, etc., from Birmingham, made by feeble-minded girls, were, as a rule, very warm and pleasing in colour, and much of the weaving, too, was remarkably satisfactory in this respect, whilst the simple pattern weaving shown was, as on previous occasions, all that could be desired. The work attempted, was, as a whole, unpretentious enough, and it was probably for this very reason that so much of it was really good of its kind. The increasing popularity of home art work is not always a good thing, but there is a great deal of hope for the future in an exhibition like this.

EMPIRE NOTES.

The New Commonwealth Office in London.—It is about four years ago since negotiations were first opened with the London County Council to acquire a suitable site for the Australian Commonwealth offices in London. Australian public opinion has held it essential that not only a good but a freehold site should be selected. It was thought, at one time, that the buildings facing Trafalgar Square, where the Strand and Northumberland Avenue converge, might be chosen, but this proposal was subsequently abandoned. The Strand-Aldwych site has now been secured by the Australian Commonwealth from the London County Council. This, without doubt, is one of the finest sites for the purpose in London. The scheme of building will involve an expenditure of over £200,000, and, together with the purchase price, will reach nearly £600,000. The interest on a considerable part of this amount will doubtless be provided by sub-letting offices, on the various floors, to the different State Governments, and possibly to some private firms. It has been suggested that if the whole of the island site in Aldwych could be acquired, Canada, New Zealand, and South Africa might erect buildings upon it, and so an Imperial centre be secured, which would be architecturally and commercially an adornment and an advantage to London, and to the Government Agencies of our Dominions.

Australian Emigration and Immigration.—The Department for External Affairs has recently issued a report, giving interesting figures as to immigration and emigration in connection with the Australian Commonwealth for last year. The statistics of emigration show that during the year the following coloured people left Australia:—Chinese, 2,310; Papuans, 548; Japanese, 462; Malays, 261; Hindoos and Cingalese, 229; Filippinos, 67; Pacific Islanders, 54; Afghans, 25; Syrians, 27; Javanese, 19; and others, 80. The total of immigrants in the twelve months, to whom the dictation test was not applied, was over 90,000, made up of:—Europeans: British, 81,457; Austrians, 816; Belgians, 50; Danes, 269; Dutch, 175; Frenchmen, 116; Germans, 2,449; Greeks, 380; Italians, 383; Poles, 11; Portuguese, 3; Russians, 35; Scandinavians, 1,210; Spaniards, 49; Swiss, 109; Turks, 10; others not specified, 25; Americans (including 27 negroes and West Indians), 786; Asiatics, 3,083; Maoris, 62; and other coloured races 821. It was not intended that Asiatics and other coloured races (excluding Maoris), which made up a total of 3,931, should have unrestricted entry into the Commonwealth. No fewer than 1,955, however, most of whom were Chinese, were able to show to the satisfaction of the officers that they had been formerly domiciled in the Commonwealth. Sixty-nine were deserters, whose traces were soon lost in the population of the Commonwealth, 627 were admitted temporarily under certificates of exemption, nine were allowed to land accredited as Government representatives on special missions, 1,525 were pearlers, 39 (mostly Syrians) came in under special Ministerial authority, 25 had passports, and 36 gained admission in connection with police-court proceedings. Of the total, 3,931, it is likely that about half would, after specific terms, leave the Commonwealth again. About 2,000 would be absorbed in the Commonwealth population, but nearly all of these would be coloured persons who were formerly domiciled in Australia. Only forty-two persons were refused admission to the

Hosted by Google

Commonwealth. The total was made up of thirty-two Chinese, five Britishers, two Japanese, one Hindoo, one Malay, and one Syrian. Two Britishers were rejected, on the ground that they were likely to become a charge upon the public, or public or charitable institutions. One of the others was considered to be insane, and the remaining two were adjudged to be disqualified, under the section of the Act dealing with persons suffering from an infectious or contagious disease of a loathsome or dangerous character. In view of the often alleged difficulties placed in the way of intending emigrants to Australia, it is certainly interesting to know that out of over 90,000 persons, only forty-two were refused admission to the Commonwealth last year, and of these only five were Britishers.

Wireless Telegraphy in Australia.—Protracted disputes have taken place in Australia between the various parties concerned in wireless telegraph systems. To these the Postmaster-General referred in the Federal House of Representatives on December 8th, and at the same time announced the Government's intention of erecting wireless stations round Australia on a system invented by the Government's wireless expert. In regard to these disputes an interesting and perhaps unique incident occurred in the great Australian Bight, when three steamers came into wireless connection. One steamer, to which a message was addressed, could not receive and reply on account of its being bound to adhere to one code. The message, however, was taken up by the third steamer, which was independent. It was eventually decided that the steamer called upon could receive a message but could not reply to it. It would be interesting to know, in the case of distress signals issued in diverse codes, whether steamers having different systems can receive messages and render aid.

New Zealand and Prohibition.—The question of the prohibition of the sale of spirituous and other liquors in New Zealand has for some time been exciting much public attention, and recently a referendum was taken on the question. The reports received as to the result of the referendum show that 255,864 votes were given in favour of the measure and 202,608 against it. The votes in favour of national prohibition thus amount to 53·93 per cent. of the total votes polled. As the proportion required to carry the proposal through is 60 per cent. the matter has fallen through despite the large majority in its favour. In many districts in New Zealand local option obtains, and, where this is so, the local vote has been three-fifths of the whole in favour.

British Columbia Fruit Lands.—Considerable interest is being evinced in the Watshan Valley orchards of British Columbia. The Valley is situated on Arrow Lake, and is reached by the Canadian Pacific Railway train to Arrowhead, and from thence by C.P.R. steamer to Needles. Some remarkable land-clearing machinery has been introduced into the district, and upwards of two acres a day can be cleared by one gang of men. Watshan Valley is being developed on entirely new lines, as settlers, when they arrive, find their selections already cleared and planted, and are thus spared a long and arduous struggle with nature before they start to make a living. According to reports, Needles is likely in the near future to develop into a large apple-growing exporting district. Experts all over Canada are watching with interest this method of clearing and settlement, and, if it proves a success, other districts will instal similar machinery for removing trees, and so greatly expedite the transition of forests into orchards and gardens suitable for immediate settlement. Blocks of land are now being offered, as an investment, to residents in the United Kingdom, and an effort is being made by the vendors to secure a Government report on each separate holding. By this means, an investor, without seeing his property, would be assured that his land is all that is claimed for it. For a small annual payment the vendors undertake to supervise and cultivate the holding, until the trees are in bearing. Until this year, no British Columbian apples have been offered for sale in England, but a few days ago a sample shipment of 600 cases was received at Covent Garden Market. The shipment was in splendid condition, and good prices were obtained. The English market is rarely glutted with a good class of apple, and there appears to be an excellent opening for British Columbian fruit.

A Floating Dock for Vancouver.—For some time past, prominent citizens of Vancouver have been promoting a dry-dock scheme for Vancouver Harbour. It is proposed to construct a dock of such dimensions that any large steamship likely to enter the port for many years to come may be able to be accommodated. It has been realised that the tonnage of vessels plying on the Pacific has been increasing so rapidly that if Vancouver is to move with the times some such scheme must be adopted, and that speedily. The proposed dock is to be 600 feet long, 55 feet deep, and 80 feet broad, and is to have a lifting capacity of 15,000 tons dead weight. Such a dock, it is considered, will be sufficiently large for the purpose, but the promoters, being aware that at the present time the bulk of the shipping entering their port is of the medium type, have arranged that the dock should be designed in two sections, which gives them practically a double plant for use, in the case of ordinary shipping. When necessary, the two sections can be joined together and thus make one huge dock. Capital for the scheme has been subscribed both in London and Paris, and joint boards have been established in those cities.

The Development of the Windward Islands.—The Governor of the Windward Islands was recently in this country, and, whilst here, made some interesting statements with regard to the developments of these islands. Before resuming his residence at Grenada he is to make a tour of the islands of St.

Hosted by Google

Vincent and St. Lucia. The islands are gradually recovering from the bad times they have been undergoing, and are now in a more prosperous condition. The cacao industry is flourishing, and St. Vincent cotton has fetched the highest prices in the world. A scheme of peasant proprietary has been inaugurated to assist small growers in the islands of Grenada. The scheme has proved a satisfactory one, and of great value to the settlers in the neighbouring islands. With a view to attracting visitors to the islands, which offer a delightful winter resort, arrangements are being made to start a large hotel at Grenada. The greater part of the trade of the islands is with the United Kingdom, but in Grenada, which has no sugar export, there is considerable commerce with the United States.

Vanilla-growing in the Seychelles.—The Administrator of the Seychelles has issued an interesting report with regard to vanilla crops harvested during the last year. The report states that vanilla plants are being gradually restricted to the higher zones of the mountains, owing to the successive dry seasons. With the legislation in France and the United States restricting artificial substitutes of this product, there has been a growing reluctance on the part of the manufacturers to use them, and this appears to be a very good reason why vanilla cultivation should be brought into greater prominence and become eventually one of the principal industries of the colony. It is true that the yield fluctuates considerably, but even the famine harvest of 1909 realised over 200,000 rupees, and was third in value in the exports for that year.

GENERAL NOTES.

International Society for the Promotion of Commercial Education.—The sixth international course of lectures on "Commercial Expansion" will be given at the Commercial High School, Antwerp, from July 22nd to August 10th, 1912. It will be organised, like previous courses, by the International Society for the Promotion of Commercial Education, with the aid of a patronage committee composed of a certain number of persons well known in the industrial and commercial circles of Belgium, and presided over by several Ministers. An executive committee, having for its president M. E. Dubois, Director of the Commercial High School of Antwerp, will undertake all details of organisation. In accordance with the main object aimed at by the various international courses of lectures on Commercial Expansion which have been given, since 1907, in Lausanne, Mannheim, Havre, Vienna, and London, it is proposed in the sixth course to study as fully as possible the economic state of Belgium, its industrial and commercial development, its political institutions, its artistic treasures, the port of Antwerp and its installations, and the colony of the Belgian Congo. The provisional programme puts forward the following sections:—(1) General survey of the geography of Belgium (one lecture); (2) Belgian agriculture (one lecture); (3) industrial Belgium (8 lectures); (4) Antwerp, port and commercial centre (five lectures); (5) other ports and means of communication (two lectures); (6) the foreign trade of Belgium (three lectures); (7) the money system, credit, and banks (two lectures); (8) political and administrative organisation (two lectures); (9) the Belgian Congo (four lectures); (10) Picturesque and historical Belgium, ancient and modern paintings; sculpture (6 lectures). For all information, apply to M. E. Dubois, Directeur de l'Institut supérieur de commerce d'Anvers; 41, rue des Peintres, Anvers, Belgium.

International Congress of Americanists.—The International Congress of Americanists have accepted the invitation, issued by the Royal Anthropological Institute, to hold their eighteenth session in London in 1912. This congress, which meets every two years, is devoted to the historical and scientific study of the two Americas and their inhabitants, and the papers read and the questions discussed during the session relate to the following subjects:—(A) Native American races, their origin, their geographical distribution, their history, their physical characteristics, languages, civilisation, mythology, religion, habits and customs; (B) Native monuments and the archæology of the Americas; (C) History of the discovery and European occupation of the New World. The congress has already met three times in France (Nancy and Paris), twice in Germany (Berlin and Stuttgart), once in Austria (Vienna), twice in Spain (Madrid and Huelva), once in Italy (Turin), once in Belgium (Brussels), once in Luxemburg, once in Denmark (Copenhagen), once in Sweden (Stockholm), and three times in America (Mexico, New York, and Quebec). In the list of countries which have extended hospitality to the congress, the name of Great Britain has hitherto been absent, although this country has taken so large a share in the exploration and colonisation of America, and is the only European Power still holding large possessions in that continent. Arrangements are being made for the session of the congress to be held at the University of London, during the week commencing May 27th, 1912.

Imports of Cheese to Belgium.—The *Bulletin* of the French Chamber of Commerce of Charleroi states that the total quantity of cheese imported by Belgium during 1910 amounted to 11,852,927 kilograms (equal to 233,331 cwts.). Of this the greater part was imported from Holland, viz., 10,123,806 kilograms; 802,104 kilograms from France, 625,671 kilograms from Switzerland, 209,153 kilograms from England, 58,591 kilograms from Germany, whilst the remaining 33,602 kilograms were supplied by other countries

Hosted by Google

Journal of the Royal Society of Arts.

No. 3,084. VOL. LX.

FRIDAY, DECEMBER 29, 1911.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

WEDNESDAY, JANUARY 3rd, 5 p.m. (Juvenile Lecture.) CHARLES VERNON BOYS, F.R.S., "Soap Bubbles." (Lecture I.)

The lecture will be illustrated by numerous experiments.

Most of the tickets have now been issued, but some still remain, which will be supplied to Members who apply for them at once.

Further particulars of the Society's meetings will be found at the end of this number.

EXAMINATIONS, 1912.

The Examinations will be held from March 25th to 29th inclusive.

The last day for receiving applications will be February 20th.

The following are the subjects:—Book-keeping, Accounting and Banking, Shorthand, Typewriting, Economics, Précis-writing, Commercial Law, Commercial History and Geography, Arithmetic, Business Training, and Modern Languages.

The Examinations will be held at any place in the United Kingdom where an Examination Committee is willing to undertake the necessary arrangements. Applications for new centres should be submitted for approval at once.

The Examination Programme for 1912, containing the regulations for the formation of new centres, syllabuses of all subjects, and the papers set in 1911, may be obtained from the Secretary of the Royal Society of Arts, John Street, Adelphi, London, W.C. (price 3*d.*, post-free 4½*d.*).

LIST OF MEMBERS.

The new edition of the List of Members of the Society is now ready, and can be obtained by Members on application to the Secretary.

COVERS FOR JOURNALS.

For the convenience of Members wishing to bind their volumes of the *Journal*, cloth covers will be supplied, post free, for 1*s.* 6*d.* each, on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

THE CARBONISATION OF COAL.

By VIVIAN B. LEWES,

Professor of Chemistry, Royal Naval College, Greenwich.

Lecture II.—Delivered December 4th, 1911.

THE METHODS EMPLOYED IN THE DESTRUCTIVE DISTILLATION OF COAL.

In the destructive distillation of coal both for gas and coke production the coals dealt with are bituminous in their character, and are comprised in classes 2, 3, and 4 of Gruner's classification—that is, they all contain enough resin constituents to yield a gas of good illuminating value and a high percentage of hard coke, but the quality and quantity of both gas and coke will depend upon the conditions under which the distillation is carried out, and these have been gradually evolved during a century of practical experience to the point which gives the results attainable at the present time. Before discussing the process of carbonisation from the scientific side of the question, it will be well to review the changes which have taken place in the methods employed; as, although they have been based largely on economic considerations, they show also the conditions which influence the yield, composition and characteristics of the various products.

When Murdoch first made coal gas at Redruth, the retort which he employed was simply a cylindrical iron pot, set in the same way that a scullery copper is over an open fire. It held a

Hosted by Google

charge of 15 lbs. of coal, was closed at the top by an iron lid, and the gas was led off 3 ins. or 4 ins. below the lid by a horizontal iron pipe. The trouble, however, of removing the coke after the carbonisation of the charge was so manifest and serious a drawback that as early as 1802 he had adopted a horizontal cylindrical vessel, from which the charge could be more easily raked out, whilst the flue was so constructed that the flame surrounded the retort and then made its escape direct into the chimney. He seems to have tried several settings of this character with retorts varying in size from 1 ft. to 20 ins. in diameter, and from 3 ft. to 7 ft. in length.

At this period also he seems to have tried a cylindrical retort placed at an angle of about 45°, with a mouthpiece at each end to aid in charging and discharging. None of these earlier forms of retort were of any great size, the usual charge he employed being about 15 lbs.; but soon after he reverted to the pot form, and, in order to facilitate the discharging of the coal, fitted into it an iron cage, which was put in before the coal charge, and which could be lifted out bodily by means of a small crane. In this he carbonised 15 cwt. of coal at a time, and in this experiment came upon a trouble which is common to every process of carbonisation in bulk, and that is that the process of carbonisation proceeds rapidly at first, producing a layer of coke next to the heated surface; and this, being a bad conductor of heat, retards the process of carbonisation owing to the slowness with which the heat is transmitted to the inner portion of the charge, whilst the gas evolved in the interior portion of the charge, having to pass through the heated coke, loses a large proportion of its illuminating power in consequence of the breaking down of the rich hydrocarbons with liberation of oxygen.

Before 1810 Murdoch had also discovered that in order to get the best gas yield a high temperature was necessary, and that if carbonised at too low a temperature the volume of tar produced was greatly increased, and the yield of gas reduced in a corresponding ratio. He also made a certain amount of progress in the setting of the retorts in the furnace by making flues around the horizontal retorts, which would ensure as much as possible of the heat being utilised.

At this period the evils arising from submitting the gas to too long a travel through the incandescent coke seem to have been generally realised by other observers, and attempts began to be made to carbonise the coal in thin layers, so that the gas should escape more freely and would not have to pass over any very great surface of heated carbonised material. A retort was patented by Clegg in 1815, which he termed a rotary retort, and which consisted of shallow boxes attached to radial arms rotating on a central shaft; the coal gas was charged in at the cool side of the shallow circular retort into the trays, and in this place also the tray of coke could be removed. Carbonisation took place on the heated side of the retort, into which the radial arms carried the tray containing the new charge. Although several installations were erected, as might be expected, they proved a failure, a fate which also befell his web retort, in which an endless chain carried the coal to be carbonised in a thin layer through the carbonisation chamber.

The advantages of a thin stratum of coal, however, having been fully recognised, Malam introduced wide oval retorts set in a horizontal position, the bottom only of which was charged with the coal, and he further made an advance in the setting by placing five and six retorts in a bench heated by three fires.

By 1841 the form of retort used seems to have settled down to an oval D-shape or circular retort, five of which were placed horizontally in the same bed or setting, and these retorts, being rapidly deteriorated by direct contact with the fire, were protected by fireclay shields or tiles.

In none of these early retorts, however, could any temperature beyond 800° C. be employed, as otherwise the exterior became so acted upon that they had a life of only a few months, whilst with the greatest care their life was seldom more than eight or nine months. Even when working at lower temperatures than those usually employed, it is found that great trouble is caused by what is known as the "growing" of iron, which takes place unless the greatest possible care is taken in the selection of the metal. This phenomenon is caused by the hydrocarbon gases permeating the metal and becoming decomposed there, so leaving a deposit of carbon, which gradually forms a spongy mass, and it is not an unusual thing for a 10 ft. retort to increase two or three inches in length after a few months' working.

This trouble with the metal retorts led to attempts being made to introduce fireclay retorts, but these met with such opposition that it was not until nearly the middle of the century that they became generally adopted. Before fireclay retorts became general, however, brick ovens were used at many places; the early ones were square and capable of containing about

Hosted by Google

4 cwt. to 5 cwt. of coal per charge, but later were altered to a flattened D-shape and increased in size, so as to be capable of receiving a charge of 10 cwt. to 12 cwt. of coal. In these carbonisation seems to have been very rapid, as five hours is given as the time taken to carbonise the charge, but the consumption of fuel was excessive, sometimes rising to 70 per cent. of the coke produced. This, however, was probably largely due to faulty construction of bad settings and furnace and general flue arrangements. Their life, however, was four or five years, and they produced coke of a very good quality.

In the early fifties fireclay retorts almost entirely displaced these ovens, and have ever since been adopted, their section being made much the same as with the old iron retorts.

As can easily be imagined, the fifty years that saw the inception of the gas industry also saw great advances in the retort settings, and these resulted in considerable fuel economy, so that by the early sixties the fuel consumption had settled down to about 20 per cent. of the coke produced. Up to this time most of the retorts had been what is termed "single-ended"—that is, closed at one end—and had only one mouthpiece; but in the larger works double-ended retorts, with a mouthpiece at each extremity, soon began to displace these.

The advances which had been taking place both in the material of the retorts and in the settings had led to a general increase in the temperature of carbonisation employed, but even in the days of the iron retorts it was found that considerable trouble arose from a crust of dense carbon deposited on the inner surface of the crown of the retort, due to the effect of heat upon the escaping hydrocarbons, and when with the introduction of fireclay retorts the temperatures were raised, this became a very serious trouble, as it led to the retort having to be scurfed at frequent intervals, and if this was done mechanically, as it generally was, great damage to the retort resulted. A slight improvement took place with the discovery that the deposit could easily be burnt off by causing a flow of air over the surface of the retort when heated and empty, which burnt off the carbon, and that a mixed steam and air blast could be used with even greater advantage for this purpose. The trouble, however, was at one time so great that it appeared as if the limit of temperature had been reached, but the discovery of the fact that pressure had an enormous influence in causing this deposit led to the introduction of the exhauster to suck the gas away from the retort, and this giving the possibility of working with little or no pressure in the retort, led to a great improvement in the amount of deposit formed, and also in the quality and quantity of the gas produced.

About 1885 Coze introduced the idea of placing the retort just at the angle of slip of the coal, so as to utilise gravity to aid in the charging and discharging, the former being done from a hopper through the mouthpiece at the upper end of the retort, whilst after the charge had been carbonised the removal of a stop and the "tickling" of the charge caused it to slide out, and this idea being gradually adopted the inclined retort has played a very important part in gas manufacture during the past twenty years, and by the application of gas-firing, and regenerative settings, very high efficiency has been obtained from them.

The idea of regeneration, which was adopted for all forms of settings, enabled heats to be attained which before had not been possible, and this, coupled with gaseous firing, gave a control of temperature the importance of which cannot be over-rated.

Since 1893, when the advent of the incandescent mantle as a practical method of developing light began to do away with the necessity for gas of high illuminating value, so general became the adoption of the mantle that in 1900 applications began to be made in Parliament in various gas bills to reduce the standard of light for those companies whose previous average had been about sixteen candles, it being felt that a fourteen-candle gas was better fitted for yielding light with the incandescent mantle, power in the gas engine, and for heating in gas stoves, than higher qualities; and it also gave the possibility of economies in manufacture, which it was hoped might lead to lowering of the price of gas to a point at which it would better compete with fuel gas for power purposes.

During the last ten years there has been an amount of activity in attempts to alter the process of gas manufacture which has exceeded any that has taken place since the first few years of its inception, and this new era may be considered to have started with the inauguration of the vertical retort, in which, by utilising a large oval fireclay retort set on end, and with a slight taper from bottom to top, much larger charges could be used than had been possible with the horizontal or inclined retorts, and in which also gravity was utilised to the full for charging and discharging.

The vertical retort dates back to 1828, when

Hosted by Google

it was first introduced by John Brunton, who, finding that the gas could not escape freely from the lowest portions of the charge, and so created considerable pressure, put a perforated pipe in the centre of the charge to afford an easy way of escape. Nothing more was heard of the process, so I presume it failed, but at later dates attempts of the same kind were made by Lowe and Kirkham, and also by Scott.

After these early experiments nothing seems to have been done for sixty years, until the summer of 1903, when Settle and Padfield put up a vertical retort at Exeter, and Dr. Bueb started experimenting on the subject in Germany.

In Bueb's patent, which is dated July 7th, 1902, he sets forth the trouble in the early forms of retort from the gas in the lower part of the charge having to traverse the column of incandescent coke above it, and proposes to overcome this by heating the retort only on three sides, and having a series of nostrils on the cool side through which the gas could escape from all parts of the charge. The fallacy of such an arrangement must soon have become manifest, as by July, 1904, an experimental setting of ordinary verticals was at work at Mariendorff. In July, 1904, also, Duckham and Woodall brought out their first patent, and with the Settle and Padfield process still being experimented with, the new era of vertical carbonisation was well started.

Vertical retorts during the last few years have met with great success on the Continent, and their use has spread with the greatest rapidity.

In England it has been felt that, good as are the results obtained with the vertical retort working intermittently—*i.e.*, by putting in a full charge of coal, carbonising and drawing, and then recharging in the same way as with the old form of retorts—great improvements could be effected by making the process continuous, as was first attempted by Settle, so approaching more nearly to uniform conditions of carbonisation. Vertical retorts on this principle have been devised by Messrs. Duckham and Woodall, and by Messrs. Glover and West, and they certainly show results which will lead to continuous carbonisation being one of the most important factors in the future of gas manufacture.

The economies to be derived from carbonisation in bulk have, on the Continent, led to still further advances in the size of the charge; and little more than three years ago chamber carbonisation was introduced at Munich, in which charges of three to eight tons of coal can be dealt with at a time, and this method also has met with a large amount of success, a number of installations having been erected on the principles laid down by Ries, Koppers, and others.

Many observers felt that the old horizontal retort could be made to yield better results than had hitherto been obtained, and Mr. C. Carpenter, at the South Metropolitan Gas Company's works, found that great advantages may be obtained by packing the old horizontal retorts full of coal, as had been suggested by Kunath in 1885, instead of only partly filling them. This does away with the large space that had always been left above the charge of carbonising coal, and so eliminates to a great extent the baking of the gases and contact with the heated crown of the retort, thus giving a distinct advance in make and quality, not only in the gas but in the tar.

At Norwich, Mr. Glover has installed a form of retort which is a compromise between chamber carbonisation and a full charge in the horizontal retort, and which has been giving a marked advance in the products obtained by the carbonisation.

As before pointed out, whilst these changes in form have been taking place, improvements in the settings, gas fuel and regenerative firing, have made such strides, that the temperatures employed are limited only by the nature of the refractory material used, and the result of these higher temperatures with light charges is to increase largely the volume of the gas obtainable per ton of coal, but at the same time its illuminating value is reduced and the tar is deteriorated, and it also gives rise to stoppage of ascension pipes and an increase in naphthalene troubles in the service.

When iron retorts were used the heats that could be employed were limited by the softening point of the iron, and rarely rose above 800° C., and although only 9,000 cubic feet of gas were made per ton of coal, the gas was rich in heating and lighting value, and the tar excellent in quality. The advent of the fireclay retort, as has been seen, enabled temperatures to be increased, and 10,000 cubic feet of gas was the general yield. With the introduction of regenerative firing the volume of gas obtained rose to 11,000 cubic feet, whilst the more modern developments approach a yield of 13,000 cubic feet.

In all these changes the gas-manager has been actuated by the desire to get the greatest volume of gas possible per ton of coal, and at the same time to do it with the greatest economy, and but

Hosted by Google

little attention has been paid to the quality of the tar and coke, which have been looked upon as by-products. In point of fact, the tar, when heats were pressed to their highest in lightly-charged horizontal retorts, became so poor and choked with naphthalene and free carbon as to be almost valueless.

The introduction of large masses of coal in carbonisation, for reasons which will be discussed fully later, has led to distinct improvements in this respect, and although there is no modern tar which approaches in value the product of the old iron retort, the improvement in many places of late has been most marked.

The idea of converting coal into coke first arose from the desire to supplement charcoal for metallurgical work by some other form of fuel which would have much the same characteristics, this being necessitated by the fact that the timber on which the charcoal supply was dependent was rapidly becoming depleted. The characteristics desired were—local intensity on combustion, strength of structure, smokeless burning and infusibility, together with as small a proportion of sulphur as possible, and the only raw coal which could have been employed to fulfil these requirements at all was anthracite, which has always been comparatively high in price and somewhat difficult to deal with in practice.

The bituminous coals, which were the ones generally available, could not, for instance, have been used in the blast furnace, on account of their swelling, softening, and forming arches, which would have interfered with the descent of the charge in the furnace and passage of the hot gases, whilst the intensity of the heat would have been low, owing to the amount withdrawn by the gases and vapours, and rendered latent in distilling off these volatile products, and also because of the oxygen present in the coal. When, however, bituminous coal is converted into coke the residue is infusible, its friability is decreased, and with the concentration of the carbon—although the total increase in calorific value is small, no heat being withdrawn by the distillation—the local temperature is very largely augmented.

With the increase in coal mining which took place in the first half of the last century, another important reason for the coking of coal presented itself. In all collieries raising bituminous coal the percentage of slack and small was high, and where any of the coal is of younger formation, the smalls will sometimes amount to 40 or 50 per cent., and as before the introduction of automatic stoking machinery the demand for this was very limited, all the screenings and smalls of a colliery had to be sold at a very low and unremunerative rate. With a comparatively small amount of labour, however, these screenings could be converted, in the old coke meilers and beehive ovens, into larger masses of hard coke exactly suited for metallurgical and furnace work.

Another reason, which was not at first recognised but has now assumed great importance, is that the sulphur present as pyrites and other sulphur compounds in all coal can be substantially reduced at a very low cost in properly made coke; this being due to the fact that the larger pieces of pyrites having been hand-picked, a considerable proportion of the impurities, including residual pyrites, can be got rid of by crushing the coal and washing it, when, being heavier than coal, it can to a great extent be separated by gravity in the trough and jigger washers. On coking the washed coal the heat expels a considerable proportion of the remaining sulphur which comes off with the gases as sulphuretted hydrogen, carbon disulphide, and other organic compounds of sulphur, whilst quenching the red-hot coke on its removal from the oven eliminates another small percentage, so that a very substantial decrease in this deleterious constituent of coke for metallurgical work can be obtained.

With the introduction and general adoption of coal gas in the early years of the last century, coke was yielded as a by-product of the destructive distillation, but the gas manufacturers, looking upon it as a by-product, have from that day down to the past few years paid little or no attention to modifying the process of gas manufacture with a view to improving the quality of the coke produced, with the result that gas coke has always been looked upon as an inferior product, and the market which it commanded has been of a limited character. It has never achieved much success as a domestic fuel, and its chief output has been due to its use by small manufacturers, for horticultural work, heat production in the gasworks, and the generation of water gas and producer gas.

Coke may be divided into two main classes:—

1. Metallurgical and furnace coke, made by processes in which everything has been done to obtain the largest yield of coke having definite characteristics, and in which the by-products, gas and tar, are either disregarded or considered of secondary importance.

2. Gas coke, made by processes designed to

Hosted by Google

give the largest yield of gas, in which as much of the carbon as possible shall be in gaseous combination, the coke residue and tar being looked upon as of secondary importance.

In making the first class of cokes the factors which are desired in the process are—using coal only rich enough in resinic volatile matter to give the necessary coking or binding properties to the mass, to crush the coal to uniform size, to use large charges, densely packed, and to carbonise for long periods, raising the outer crust of coke first formed to as high a temperature as possible, so that, as the heat penetrates into the mass, the hydrocarbon gases and tar vapours being evolved shall be decomposed by contact in their passage through the envelope of red-hot carbon, depositing as much of the gasified carbon as possible, so that it is only the more stable hydrocarbon gases and most volatile vapours that escape; the ideal carbonisation from the coke-maker's point of view being the retention of the whole of the carbon in the mass.

In gas manufacture, on the other hand, in the ordinary process employed at over 90 per cent. of gasworks, the coal used is as rich in resinic volatile matter as can be obtained without going to undue expense. Small charges are used in order to reduce the time needed for carbonisation, and also to reduce the contact with too large a surface of hot coke, and the temperature employed is limited only by its effect on the life of the refractory material used, and to avoid stopped ascension pipes and other troubles inseparable from overheating, and to continue the carbonisation only long enough to drive out all volatile matter. Under these conditions the gas yield is increased to the highest limits compatible with leaving in it enough hydrocarbon gases to comply with parliamentary requirements as to illuminating and heating value, and the coke is looked upon as a by-product that will pay a share of the coal bill; the ideal condition of carbonisation from the gas-manager's point of view being the conversion of the whole of the coal into gas, an ideal within measurable distance when using high heats obtained by employing 15 per cent. of the coke for heating the settings and converting the remainder into water gas.

It is clear that two ideals so fundamentally opposed to each other must be hard to reconcile, and in its broadest sense the question is simply—Given a definite weight of coal, how can it best be used to avoid waste and secure the highest monetary return, whilst at the same time satisfying the requirements of the various classes of consumers? Simple as the query seems at first sight, it is one that demands a consideration of the whole of the procedure in the various methods of carbonisation practised.

The classes of coals used for making metallurgical and furnace coke are those which on heating fuse to a sufficient extent to convert the mass of powdered coal into a pasty mass, from which on slow heating the volatile matters distil out, leaving a fixed carbonaceous residue which binds the free carbon into a hard mass.

It seems probable that the nature of the luting material between the particles when a coking coal is carbonised, is entirely dependent upon the temperature attained and the length of time for which it acts. It is, in fact, the residuum of the least volatile portion of the coal, and if the action has not been carried on for a sufficient length of time at a high enough temperature, hydrogen and oxygen will be found in it, and the last traces of these are very difficult to eliminate.

It is only coal that contains a certain quantity of bituminous matter that will yield a well-caked coke. If we take coals containing a very high percentage of carbon, like anthracite or steam coal, they will not coke; and in the same way tertiary coals, like lignite, containing a large proportion of humus, will not coke, so that the largest proportion of coking coals come in the true bituminous class. Thus, the coals used for gas making are nearly all coking coals, with the exception of cannel, which is now very little employed, and in which the high ash content is a drawback.

The coking coals themselves, however, may be divided into two classes—(1) the most bituminous, which give the largest percentage of gas, and are so chosen for gas making, and (2) the less bituminous, which are the best for cokeworks; the reason being that high gas yield means a high proportion of carbon lost as hydrocarbon gases, whilst this loss is less as the volatile matter decreases, enough, however, remaining to yield the pitch for binding purposes.

The degree of heat and rapidity with which the maximum temperature of the outer layer is attained affects the coking properties of some kinds of coal, and some of the South Staffordshire coals, which when slowly heated yield a friable mass useless as coke, will, when heated rapidly to a high temperature out of contact with air, yield a hard coke. This is due to the hydrocarbons all escaping as gases and vapours when slowly heated, whilst they are largely decomposed to pitch when they have to pass through an exterior mass of coke at a high temperature, and so yield the necessary binding

Hosted by Google

material. Indeed, it is generally found that the coals showing the least caking power must be carbonised quickly at high temperatures if successful results are to be obtained.

With highly bituminous coals like the Durham and Yorkshire, on the other hand, quick heating would lead to such frothing and swelling of the mass, owing to the large volume of the gases liberated, that it is difficult to carbonise them in any of the narrow-chamber ovens, and when we are blaming the North Country coke-makers for not adopting the more modern forms of oven and by-product recovery plant, we should bear in mind that it is because they find the beehive oven far superior for the class of coal on which they have to work.

When the idea of coking coal first arose, as might be expected, the same methods as in charcoal burning were employed, and heaps of coal were ignited on the ground and the combustion checked by coating with damp coal-dust. A small advance was soon made by building a brick shaft or chimney with openings in the side to allow the passage into the shaft of the gases and volatile vapours issuing from the heap of coal piled around it, and so arranged that the largest coal was nearest the middle. The mass was ignited by burning coal introduced into the shaft, and air inlets were made along the ground into the heap, the combustion being afterwards checked by coal-dust, ashes, etc., spread over the outside. Such a method of carbonising was most wasteful, but produced a good coke where a certain quantity of volatile matter was not a drawback, and "meiler coke," as it was called, is still made on a small scale.

In these processes the heat was given partly by the combustion of some of the coal, and partly by the gases and vapours, and the meiler heaps soon began to be displaced by "oven" coking, which gave a more uniform product and a larger yield of coke.

The early ovens were heated entirely by the combustion of the vapours and gases, together with a small proportion of the coal within the oven, no external heat being employed. These ovens, called "beehive ovens," on account of their domed tops, were 12 ft. wide by 10 ft. deep, and held a charge 10 ft. in depth; the walls were 2 ft. thick, and the ovens were built in groups to retain heat and minimise brickwork. They had a hole in the top of the dome $2\frac{1}{2}$ ft. in diameter, which could be closed by a plate, and an opening in front for charging or drawing, fitted with a sliding door in an iron frame, the door being provided generally with air inlets adjustable at will. The charge could be introduced either through the hole at the top or by the door, but it was found that the coke was of more even density if charged by the door, as when shot in from the top a dense mass of smalls was formed under the hole, which carbonised more slowly than the rest, and so gave a less uniform quality of coke.

In Silesia ovens of much the same kind were employed, but the top was kept closed, a little air was admitted at the bottom and sides, and the gases and vapours were led by a side tube into a tank of water, where the tar condensed and the gas escaped.

In both these forms of oven the new charge introduced fired from the bottom if the structure remained hot enough from the last charge, but as soon as the gas began to be evolved it burnt above the charge, and the heat spreading downwards through the mass continued the carbonisation, the completion of the action taking eighty-four to ninety-six hours per charge of seven tons; at the end of this period the top cover is put on and the oven is allowed to cool down for twelve hours; the coke is then drawn by rakes and quenched with water.

The beehive oven still rules supreme in Durham, Scotland, and America, and the latest form utilises a portion of the waste heat, to do which the ovens are built back to back with a flue between them, the suck of a chimney drawing the hot products of combustion and incompletely-burnt gases through the furnace space of a Lancashire boiler, and so utilising them for raising steam.

Many more alterations have taken place in coke ovens than with gas retorts, and in dealing with the earlier forms I can only glance at those that have proved most successful and were the forerunners of the present systems, which have now settled down to the beehive as the survival of the internally-fired oven, the only remaining rival to the externally-fired by-product recovery systems.

Many forms of coke oven were introduced in the sixties and seventies, the two most interesting being the Coppée and the Appolt, the former being the forerunner of the present recovery plant, and the latter of the modern vertical retort.

In the Coppée ovens the carbonising chambers were long and narrow, with sides slightly tapering from back to front, and about 3 ft. 6 ins. high. Crushed coal was fed into them from the top, and was carbonised by the combustion of the gases evolved from the coal, which escaped

Hosted by Google

through openings in the side into flues between the chambers, where it met an air supply and burnt, heating the sides of the chamber. The ovens were built in batches and were charged in rotation, so as to equalise as far as possible the heating value of the escaping gas, which is large in volume and high in calorific value during the first half of the carbonising period, and rapidly falls during the second, and when the action was completed the coke was pushed out from the oven by a ram, both ends of the oven being closed by doors.

These ovens were introduced at Chapeltown, near Sheffield, in the early seventies, and about the same time at Ebbw Vale, and contain many of the characteristics found in the modern recovery plant ovens.

The Appolt oven consisted of a rectangular structure containing twelve coking chambers or built-up rectangular retorts, having a top section of 3 ft. 8 ins. by 13 ins., and a bottom section 4 ft. by 1 ft. 6 ins., and between the chambers flues varying with the taper of the retorts. Vents in the side walls of the retorts allow the gases and vapours to pass into the flues, where, meeting the air supply, they burn and yield the necessary temperature.

The retorts were fitted with doors at top and bottom, so that they could be fed and discharged by gravity. These ovens were used as early as 1857 in the collieries of the Pas de Calais, and the large heating surface constituted a great advance on any previous form of oven.

About the sixties various attempts were made to introduce ovens, from which it would be possible to collect some of the by-products, but no very successful result was obtained until about 1879, when Simon and Carves introduced a recovery plant in which, taking the Coppée form of oven, they closed the side exits for the gas into the flues, and led it off by a dip pipe and hydraulic main to condensers and scrubbers, which extracted the tar and ammonia, the gas being led back to the ovens and burnt in the flues to heat the chambers.

Soon after this, ovens of the same character were introduced by Dr. Otto, which differ from the Simon-Carves plant chiefly in the arrangement of the combustion and heating flues, and in making up for the loss of heat due to removing, cooling and scrubbing the gas before combustion, by using Siemens regenerators to extract the heat from the flue gases and highly preheat the air used in the combustion.

During the past thirty years many improvements have been made in the earlier forms of recovery plant coke ovens, and at the present time only half the gas produced in the carbonisation is needed for firing the ovens. This has led to attempts being made so to arrange the working of the plants as to fit them for the production of the gas supply for large towns, the economies incidental to working with large charges offering an important reduction in the cost of coal gas, and as soon as legislature abolishes the absurd trammels that bind the English gas-maker to a standard of illuminating value, which means nothing, and adopts a standard of heating power, which means everything, some advance may be made in this direction in localities where there is a good market for metallurgical coke.

In spite, however, of the enormous economies in coal, ammonia and tar products, and improvement in atmospheric conditions brought about by the recovery plant, less than one-third of the coal used for coking is carbonised in such ovens the old beehive oven still holding its own in the north of England, polluting the air and wasting the commercial assets of the country to an even greater extent than it did in the first half of the last century, when it had the field to itself—and to explain this extraordinary state of things we must look beyond our insular prejudice and inertia.

The real cause is, as we have seen, that the very "fat" gas coals of the northern fields do not lend themselves to carbonisation in narrow chambers or vertical retorts filled to the utmost by ram or gravity. The great rapidity of evolution of the gas during early periods of the carbonisation leads to such frothing up and swelling of the semi-fused mass on the exterior of the charge that trouble ensues.

Coke varies very much, not only in its chemical and physical characteristics, but also in external appearance. It may generally be accepted that with the same kind of coal the higher the temperature, and the longer the exposure of the coke to it, the harder, more dense and less easily combustible will it be, whilst the appearance is largely conditioned by the method of carbonisation.

In the beehive oven, where most of the heating of the mass is from the top, the escaping gases from the carbonising coal have to pass upwards through the whole mass of red-hot coke above, contact with which decomposes the hydrocarbons and deposits the carbon in almost metallic-looking films throughout the mass, and this gives the bright light grey surface that used to be so highly prized in the beehive coke. On

Hosted by Google

the other hand, if the gases are drawn away so as to prevent as far as possible excess of surface contact and pressure, this silvery appearance is not produced, and the coke looks black and dead, as is seen in gas coke and also to a less extent in recovery oven coke.

Some observers claim that this deposition in bright films is characteristic of the decomposition of methane, and is given only by this particular gas, but the difference in the form of the deposited carbon is due to whether it has been decomposed by radiant heat or contact heat. If an easily decomposed hydrocarbon like acetylene is heated by passing between the walls of a very highly-heated tube placed vertically to lessen contact as far as possible, the radiant heat is sufficient to decompose it, and the carbon is deposited as a cloud, but where the hydrocarbon is more resistent and comes in actual contact with the heated surface, then the carbon is deposited in a dense form as a film of great density, which in time builds up masses of retort carbon, and it is only when the film is very thin that the bright appearance is produced. The duller surface of recovery oven coke gave rise to great prejudice against it in the minds of the iron smelters when recovery plant was first introduced, but this was probably caused by the fact that until the recovery plant was perfected—the heat being applied from the outside of the oven instead of the inside, as with beehive ovens—the coke was not so thoroughly carbonised, was softer, and too easily attacked by the carbon dioxide in the blast furnace, and so not so strong or so economical in practice.

In most oven carbonisation the face of the coke nearest the hot wall of the furnace shows a curious undulated surface, consisting of discs 6 ins. to 8 ins. in diameter, and higher at the centre than at the periphery—these are generally known as "cauliflower heads" by the coke burners, and crevices of cleavage run into the mass from the lowest point to the area which was last heated to the fuel temperature in the carbonising process. So regular are these appearances, and so like the columnar structure found in some formations, that they have sometimes been spoken of as if they represented a form of crystallisation, which is, of course, wrong, and they appear to be formed from the escape of gases, which causes the whole mass to swell; after the first few hours this ceases, and a general contraction of the whole body takes place, which being fairly even in every direction fissures the coke in circular masses. If the coke is drawn when the volatile matter just ceases to come off, the heads are not found, but the crevices are there. The coke, however, is left heated to its highest temperature for a considerable period to harden it, and this causes further shrinkage, which, taking place mostly where the crevices have been formed, owing to the heat entering the mass most easily at these points, leaves the central portion between the cracks standing up a fraction of an inch above the densest parts.

Near the doors of the oven, black, dull-looking masses of coke are often found, resembling gas coke, and known as "black heads"; these are formed by the coke at this point not being sufficiently heated to complete properly the carbonisation.

As a rule it is found that the higher the temperature at which the oven has been worked, the more thorough has been the decomposition of the hydrocarbon gases and vapours passing through the red-hot coke, and the carbon so deposited increases the yield. High temperature and long exposure to the heat after carbonisation is finished also render the coke harder, denser, and less easily ignited.

The composition of the coal has so great an influence on the yield of coke, that any comparisons of the percentage yield by the various forms of oven are bound to be misleading, but the alterations from the earlier forms of oven to the modern oven may be taken as representing a 10 to 12 per cent. greater yield of coke.

Taking it very roughly, a good caking coal containing 87 per cent. of carbon would yield:—

Carbonised in heaps	61 per cent.
,, ,, beehive ovens . .	64 ,,
,, ,, Appolt and Coppée	68 ,,
,, ,, modern recovery ovens	68–77 ,,

whilst the by-products, tar and sulphate of ammonia, also form an important asset.

The improvements in the recovery ovens since their first inception have been largely in the arrangement of the flues for heating the sides of the chambers, the superiority of vertical over horizontal flues being now generally admitted, and allowing the necessary temperature to be attained with a consumption of less than half the gas produced by the carbonisation.

A great difficulty that was found was to get even and continuous heating of the chamber walls, as when in the early Hoffman ovens the Siemens regenerative principle was adopted, the alternate application of heat to only one-half

Hosted by Google

the chamber wall, the heating being alternated every half-hour, gave fluctuations in temperature which affected the carbonisation and strained the brickwork; and this same trouble was found in the United Otto and Koppers ovens.

In his later oven, introduced in 1905, Dr. Otto doubled the number of regenerators, so as to reverse alternately in four sections, whilst Coppée in his newest type makes the reversal in five sets out of ten sets of flues, and Collin extends the reversal to alternate flues, thus ensuring the most even temperature.

Other alterations have been made in the handling arrangements and in the plant for the recovery of the by-products, which are now nearly equal in quantity to those obtained in gas manufacture, so that, as far as the products of the carbonisation go, we may state the approximate performances of the two methods as being:—

	Coke.	Gas.	
Gas making .	13 cwt. inferior coke, less 2·6 for heating.	12,500 cubic feet, 15 candle-power	Tar, sulphate of ammonia, cyanogen—about equal.
Coke making .	14·2 cwt. superior coke .	9,500 cubic feet, 10 candle-power, less 4,500 for heating.	

EXPERIMENTS ON THE STRENGTH AND FATIGUE PROPERTIES OF WELDED JOINTS IN IRON AND STEEL.*

These experiments were undertaken at the suggestion of Sir John Wolfe Barry in 1908, the object being to obtain a comparison of certain properties of welded joints—made by different processes and by different makers—with the corresponding properties of the unwelded material from which the joints were made. It was hoped that by this means some estimate of the general reliability and efficiency of modern welding processes might be arrived at. In order to obtain material for the work, a circular letter was sent from the National Physical Laboratory to various engineers, inviting them to submit specimens of welded joints for testing. Sixteen firms responded to this invitation, and the total number of welded joints received was 167. The method of welding and treatment of the joints was left entirely to the makers, the only condition being that all specimens should be made from bars 1¼ inch in diameter. The tests to which the joints were subjected were: first, a tensile test, and secondly, a fatigue test by the Wöhler method. The former included determinations of the elastic limit, the yield point, the maximum stress, the total elongation, and the general and local elongations.

For the rapid carrying out of the fatigue tests a machine was constructed in which the specimen was rotated at a speed of 2,200 revolutions per minute. Owing to the results of a previous investigator with another type of machine having shown a decided reduction of fatigue strength with increased rapidity of stress alternation, preliminary experiments were carried out to determine the amount of this effect for the particular type of machine used. The results showed that for speeds of 200 and 2,200 reversals per minute there was practically no difference in the fatigue strength. The assumption was therefore made that the apparent reduction of fatigue strength with rapidity of alternation in the case referred to was a characteristic of the machine used.

The mean results of the tensile tests on the welded joints, expressed as a percentage of the strength of the original material from which the joints were made, were:—

Hand-welded iron	89·3 per cent.
Hand-welded steel	81·6 ,,
Electrically-welded iron . .	89·2 ,,
Electrically-welded steel . .	93·4 ,,

Joints made by the oxy-acetylene process were also submitted by two makers, but the results were not comparable with those obtained by the hand or electric processes.

The various determinations made in the tensile tests showed a distinct want of uniformity in the material in the region of a weld, but the results of the fatigue tests proved that this does not materially affect its resistance to reversals of stress. When failure under alternating stresses of low value takes place, it is invariably due to a defect in the actual weld itself. The number of defective joints which were discovered in the whole investigation, however, leads to the broad conclusion that in important work, where the failure of any particular welded joint may involve serious damage to the structure, the subjection of each joint to a proof load is still desirable.

* Abstract of a paper read by T. E. Stanton, D.Sc., M.Inst.C.E., and J. R. Pannell, at the Institution of Civil Engineers.

HOME INDUSTRIES.

The Industrial Unrest.—The year goes out with general unrest in the labour world. The Master Cotton Spinners and Weavers of North and North-East Lancashire have met the demand of the weavers' trade union for the employment of only trade unionists, by deciding on a lock-out. The members of the association own 420,000 looms, and employ about 160,000 workpeople, of whom some 140,000 are weavers. The cotton waste manufacturers, who have decided to join hands in the dispute with the master weavers, control 300,000

Hosted by Google

spindles and over 10,000 looms, and employ about 6,000 workers. Although the lock-out does not directly affect the spinning mills of South and South-East Lancashire, they cannot go on working for an indefinite time if the weaving sheds are not absorbing their output. It is earnestly to be hoped that the threatened lock-out may be short, but at the moment the outlook is not promising, the trade union weavers believing that in the present profitable state of the trade the employers will not hold out very long. On the other hand, the employers are said to be determined not to be coerced, and to insist upon their right to engage those who are honest, diligent, and skilled, without imposing upon them any such test as that involved in the present action of the operatives' unions. The crisis in the coal trade is not over, and little progress seems to have been made in the fixing of a minimum wage, and in the payment for abnormal places. In Dundee, the stoppage due to the carters' and dockers' strike, which made 30,000 workers idle, is over, but the dispute has been bitter and prolonged. In other industries there is discontent, which may at any moment become acute, and though these trade difficulties have a way of settling themselves unexpectedly, the outlook for the New Year, as bearing upon the relations of masters and men, cannot, as matters stand, be said to be other than very disturbing.

Cotton Spinning Profits.—Mr. William Tattersall has just published his annual analysis of trading results of Lancashire cotton spinning companies. The figures cover the twelve months ended November 30th last, and relate to seventy-six mills with a share capital of £2,806,798, and loans of £1,394,792, and show that, though the results are better than they were in the preceding twelve months, they are anything but satisfactory. The value of the machinery, including plant, of the seventy-six mills amounts to £3,288,317, and the total spindleage is 6,570,532, there being 2,687,348 twist and 3,883,184 weft spindles. Of the seventy-six companies, forty-five made a total profit of £79,724, and thirty-one report a total loss of £48,711. The profit on share capital works out at a little more than one per cent. per annum, while the gain on share and loan capital combined is three-quarters per cent. per annum. The result is very poor, but in the previous year the loss on share capital was over 10 per cent. per annum, and on share and loan capital combined over 7 per cent. per annum. Given the avoidance of labour troubles, the current year promises much better. For the last three months spinners have been doing a remunerative trade, and satisfactory profits may be anticipated.

A Great Shipping Combination.—A few weeks ago the shares of the Union-Castle Mail Steamship Company might have been bought at about £13, at the end of last week they stood at £28. This immense advance in price is of course due to the official announcement that the Royal Mail Company and the Elder Dempster Company have purchased the assets of the company, thereby putting a total of about 1,300,000 tons of shipping more or less under the control of the Royal Mail Company, and making it the largest shipping company in the world, its tonnage exceeding by about 150,000 tons that of the International Mercantile Marine Company. The terms upon which the Union-Castle shareholders are to part with their shares will seem strangely generous to those who did not know that the shares have been in the past considerably undervalued, the balance-sheet and profit and loss account not disclosing the real position, which would have allowed much larger dividends. And so it comes to pass that the Union-Castle shares of £10 each are to be taken over on the basis of £32 10*s*. per share, while in respect of the year ended December 31st last a dividend of 4¾ per cent. is to be paid. A condition of the purchase is that Messrs. Donald Currie and Co. resign the managership, and undertake not to be interested as owners, directors, or managers in any competing line of steamers. As compensation they are to receive £700,000, out of which they will pay the vendors' costs in relation to the sale of the shares, and contribute £50,000 to the pension fund of the company. The Royal Mail Company and Elder Dempster and Co. will have to find £4,781,653 in cash to carry out the purchase, and it is not known as yet how it is proposed to raise this sum, but in one way or another the capital of the Royal Mail Company, which now, including debenture stock, stands at £3,700,000 will have to be increased to £6,250,000, assuming it has only to provide one-half of the purchase price; but it is believed that whilst the present prosperous condition of the shipping trade lasts the net profits on the share capital of the combination will be very substantial, even if the company loses the South African Government's mail contract, which means £135,000 per annum.

Cement Combination.—It is long since the cement industry was in a satisfactory condition. There are too many companies engaged in the trade, and an attempt is being made to consolidate the industry in a few hands, with the object of putting an end to the reckless cutting and violent fluctuations in price which have done so much to injure the business in the past. For this purpose, the British Portland Cement Manufacturers (Limited) has been formed, with a share capital that now stands at nearly £3,000,000, and with power to issue debenture stock dependent upon the amount of the issued share capital. The company will take over and amalgamate a large number of cement works and businesses, including the largest undertakings outside the Associated Company, with which it will have a working agreement. The consolidation of competing interests is expected to result in more efficient organisation and increased economy of working. Existing works will be improved, in some cases more up-to-date plant will be put in, and much money will be saved in

Hosted by Google

transport charges. For example, the Thames and Medway works have been in the habit of sending large quantities of cement into districts which can be much more easily supplied direct from one of the local works, and these works will be included in the new organisation. It is believed that those who have the project in hand can command the financial resources necessary to carry it to a successful issue.

A Cotton-Picking Machine.—Dr. Fischer has just given the Technical Commission of the German Colonial Agricultural Committee reasons for the conclusion that the Campbell cotton-picking machine has great commercial value. He states that one machine can easily pick 5,000 lbs. of cotton per day, and under favourable conditions as much as 10,000 lbs., whilst the machine only requires a man and a youth to work it. After estimating all working costs, and allowing for depreciation, Dr. Fischer estimates that the picking cost is about 1*s.* 5*d.* per cwt. as against 4*s.* 2*d.* per cwt. for hand labour. Dr. Fischer suggests making large-scale experiments with the machine in the German African colonial cotton-fields, but he admits that it may not prove so suitable for the class of cotton grown there as in America. The price of the machine f.o.b. New York is put at £1,000, whilst the weight is about 4½ tons. The makers are the Price-Campbell Cotton-Pickers Corporation, and they expect to produce 12,000 machines during the next four years. If the machine can really do what is claimed for it, its importance to the cotton industry is demonstrable.

Flannelette.—Makers of flannelette were considerably perturbed by the announcement that a Bill before the Commonwealth Parliament proposed to subject the ordinary kinds of flannelette to a duty of 20 per cent. *ad valorem*, whilst allowing flannelette rendered non-inflammable by some chemical process to come in free. The manufacturers understood that the test for inflammability was one that no cotton cloth could have successfully withstood, and the consequent alarm of makers is intelligible. There is quite a large trade with Australia in these goods, and the introduction of the Bill was followed by many "stop" orders. Fortunately, the proposal has been dropped, doubtless owing to the representations of the Australian importing houses to the Commonwealth Government.

Malleable Iron.—It is expected that the protracted negotiations among the Scottish malleable iron makers for the amalgamation of their businesses will be brought to a finish at a meeting to be held in Glasgow this week. One of the difficulties in the way of the combination is the question of the valuation of the works of the respective makers, who number seventeen, and whose interests are not all the same. Some of them produce other classes of material, and they have raised many difficulties. It was only in April last that the Association of Scottish Malleable Iron Makers came to an end, and it was understood that the rupture of the combination was due to illicit undercutting of prices by members of the association.

Improvements in Laundry Processes.—For some years the leading German passenger-carrying ships have been provided with the electrolytic system for disinfecting linen, and a year ago the Cunard Steamship Company fitted up their laundry at Liverpool with two "Manchester" electrolysers. The White Star line has now decided to instal a similar plant, and it may be expected that the electrolytic sterilisation of linen in public laundries will soon be general.

CORRESPONDENCE.

THE FISHERIES OF BENGAL.

As an old resident of Calcutta I listened to Dr. Jenkins's interesting paper on the Fisheries of Bengal (reported in the *Journal* of December 22nd) with the deepest interest. He is to be congratulated upon placing on record a valuable account of the scientific results of the many voyages of the "Golden Crown." These voyages were discontinued, however, not from any inability to obtain a large and varied supply of fish from parts of the Bay often far distant from the city, and bringing it safely and in good condition to land, but from the fact that after it left the steam-trawler the storage and disposal of the haul were dealt with by the authorities concerned upon unbusinesslike lines. The ventures so ably conducted by Dr. Jenkins and his staff of practical men were rendered largely abortive for practical purposes by reason of the delay in getting the fish on to the market. I believe a substantial portion of each supply was carted to a place called Balliaghatta, for cold storage on the premises there of a local ice manufacturing concern, who happen to possess the necessary refrigerating plant. Balliaghatta is a considerable distance beyond Scaldah, which again is well removed from the great market centres. By the time the fish had travelled miles and miles from the Hooghly to the ice factory, and thence back to the markets for the consumer at the breakfast-tables of hotels, steamers, and private residences, under the fierce climatic conditions of a tropical district, it had often ceased to be palatable, and wise men took to avoiding it with a unanimity born of unpleasant experience. I once saw a small mountain of it being carted away for manure. No doubt the native fishing industry, considering their craft more or less in danger, succeeded in persuading the khausamahs, bobachees, khitmutghurs, and others, who had the ultimate handling of the fish for the table, to find it worth their while to accentuate the difficulties

Hosted by Google

of land transport and distribution, and thus to render the wares of the "Golden Crown" unpopular; but apart from this, the absence of sensible arrangements for the disposal for practical use of the costly hauls was widely commented on. The ship may be said to have been lost for the sake of the proverbial "ha'p'orth of tar." The fish were not primarily wanted for the show-cases of the India Museum, they were wanted for breakfast, and the failure to realise this accounts for the relegation of the activities of the "Golden Crown" to fresh shoals and channels new, to the vast delight and profit of the native fishing fraternity, who deserve all they get, for they work hard for it.

Dr. Jenkins's efforts were eminently successful so long as his control over the catch held. Their apparent failure in the end arose from the lack of foresight essential to the putting through of so bold an experiment by the Department he served.

WILMOT CORFIELD.

OBITUARY.

SIR FRANCIS SHARP POWELL, BART.—Sir Francis Sharp Powell died at his residence, Horton Hall, Bradford, on the 24th inst., at the age of eighty-four. After attending the Grammar Schools of his native town, Wigan, and Sedbergh, he proceeded to St. John's College, Cambridge, of which he was elected a Fellow in 1851. He was then called to the Bar, and practised on the Northern Circuit for a few years. In 1857 he was returned as M.P. for Wigan, which he represented till 1859, when he was defeated. During the next twenty-five years, Sir Francis fought a great many elections—during his whole career it is believed that he fought more elections than any other Member of Parliament. For a time he represented the borough of Cambridge; on losing this seat he stood unsuccessfully for Stalybridge. In 1872 he was elected for the North-West Riding of Yorkshire—a seat which he only retained for two years. He also stood for one of the divisions of Manchester, but was again defeated. In 1881 he returned to Wigan and won the seat, but the election was declared void on petition, and the writ was suspended for a time. In 1885, however, his fortune turned; he was again elected for his native town, and he continued to represent it—though not without contested elections in 1886, 1892, 1895, 1900, and 1906—until his retirement from public life in 1909.

A staunch Conservative, Sir Francis was a keen supporter of denominational education; he contributed liberally to the cause of Church extension, and he built All Saints' Church, Bradford, and its school, at a cost of some £30,000. He was for many years Chairman of Governors of Sedbergh School. A baronetcy was conferred on him in 1892, and ten years later he was elected an honorary Freeman of Bradford. He was among the oldest members of the Royal Society of Arts, having been elected in 1854.

JAMES AITCHISON.—Mr. James Aitchison, the founder of the well-known firm of Messrs. Aitchison and Co., opticians, died on the 22nd inst., in his fifty-second year. A liveryman of the Spectacle Makers' Company, he was keenly interested in encouraging study and research among members of the optical trade; he was one of the founders of the Optical Society, and it was largely through his exertions that technical classes for opticians were established at the Northampton Institute, Clerkenwell. He also took a prominent part in calling the Optical Convention in 1905, and he was treasurer of the guarantee fund for the Optical Convention to be held in 1912. Mr. Aitchison joined the Royal Society of Arts in 1902.

GENERAL NOTES.

METALWORK AT THE VICTORIA AND ALBERT MUSEUM.—The Department of Metalwork has recently made several important acquisitions. Chief among them is a serpentine tankard with silver mounts, dating from the reign of James I. It has a peculiar interest, from the fact that its form is transitional between the slender domed-lid tankard of the previous century and the stouter form of a later period. The decoration shows no traces of German influence such as would be found on silversmiths' work of Tudor times, but the engraving on the lid recalls the designs of Michel le Blon. The workmanship is of the highest quality, and suggests that the silversmith was one of the foremost craftsmen of his day. The tankard is exhibited in the case of new acquisitions in Room 26.

A pre-Reformation English chalice and paten, also acquired recently, are exhibited in the same case; they date from the fifteenth century, and are of silver parcel-gilt. The centre of the paten is engraved with the face of Christ, and the foot of the chalice with the Crucifixion. The number of existing pre-Reformation chalices is small, and the one acquired by the museum is valuable, not only for its rarity, but also for its excellence of design.

A silver sweetmeat dish, with hall-mark for 1633, in the same case, affords a good example of a type of work produced in England in the time of Charles I. and the Commonwealth; similar pieces are to be found in use as alms dishes in churches, but as the period of their production lasted only some thirty years, they are naturally rare. A circular silver dish, with escalloped border, illustrates the earlier style of the French silversmiths, who left their country on account of the revocation of the Edict of Nantes and settled in England. The bowl is the work of Isaac Liger, and bears the London hall-mark for 1719. It is delicately engraved with ornament in Louis XIV. style. There is also exhibited in this case a Spanish casket, the panels of which are decorated in repoussé with bold strapwork, and framed

Hosted by Google

in richly gilded bronze—a characteristic example of the vigorous work of the first half of the seventeenth century. In Room 39 several cases are devoted to the exhibition of a collection of over two hundred pieces of Sheffield plate. With the exception of a few pieces of late date, illustrating the development of the manufacture, and two or three pieces of foreign make, valuable for comparison, they represent the finest period of the manufacture—the second half of the eighteenth century. The collection includes a large number of examples of the pierced work for which the Sheffield makers were celebrated. The perfection of form and decoration shown in these productions almost surpasses what is found in solid silver of the period, and can only be explained by the collaboration of designers of first-rate ability with very highly skilled craftsmen. The department has also acquired a small, but very choice, collection of Japanese swords, formerly in the collection of Mr. Alfred Dobrée. It is temporarily shown in the second sword-case in Room 16, and includes unmounted blades by perhaps the most famous of Japanese swordsmiths, Masamune (died 1344), as well as by Umetada Hiōju (about 1650), and other smiths of hardly less note. There is also a superb set of fittings for a blade, including a scabbard of the rare green lacquer; the metal mounts, decorated each with a tiger, are in the finest eighteenth century style. In the same room is exhibited a series of over 300 Japanese sword-guards (*tsuba*), acquired from the Hawkshaw Collection. It illustrates the varieties of material and methods of workmanship, and of design and style, characteristic of the sixty or more distinct schools of craftsmen who were engaged over a period of nearly four centuries in making sword-furniture. Several ancient Chinese bronzes have been added lately to the collection, including a wine-bottle, intended to be carried on campaign, the lid forming a cup; it dates, probably from the Shang Dynasty (1766 to 1122 B.C.). Together with a tripod sacrificial bowl with thick green patina and archaic relief designs, dating probably from the same period, it is shown in Room 12. Two pieces of later date, perhaps of the Han Dynasty (206 B.C. to 221 A.D.), recall the shapes and style of an earlier time. One is a ladle for hand-washing at sacrifices, of very graceful shape, the other a large offering-bowl on three feet, with monster handles, and containing a dedicatory inscription of the usual type. These are also shown in Room 12.

THE GOLDSMITHS', SILVERSMITHS' AND JEWELLERS' ART COUNCIL.—Over sixty prizes, varying in value from £10 10*s*. to 10*s*. 6*d*., are offered by the Goldsmiths', Silversmiths' and Jewellers' Art Council for competition in 1912. First, second and third prizes, of the respective values of £10 10*s*., £5 5*s*. and £2 2*s*., are offered to designers of (1) goldsmiths' work, (2) silversmiths' work, and (3) jewellery. Other prizes, of £5 5*s*., £4 4*s*., £3 3*s*., £2 2*s*. and £1 1*s*., for worked objects are offered to goldsmiths, silversmiths, small workers, jewellers, chasers, engravers (heraldic), ring makers and modellers, and prizes of smaller amounts to apprentices in most of these branches. The funds for the prizes have, in nearly all cases, been provided by the Worshipful Company of Goldsmiths. A travelling scholarship, open to students in the technical schools, will also be offered shortly. Further particulars may be obtained from the Secretary of the Council, 30, Theobald's Road, W.C.

POPULATION OF ITALY.—The results of the last census of Italy have just been published by the Minister of Agriculture, Industry and Commerce. From this, it results that the total population of the kingdom last June amounted to 34,686,653, as compared with 32,475,233 in 1901. This shows an increase of 2,211,420 persons in ten years and four months.

THE EGG TRADE IN GERMANY.—The consumption of eggs in Germany has increased considerably during the last ten years. The number of boxes imported to that country from Austria-Hungary during 1910 amounted to 539,242 as compared with 531,740 of the previous year. From Russia, the number of boxes imported last year was 624,470, against 503,197 in 1909.

THE COMMERCIAL RESOURCES OF TRIPOLI.—Signor Vigoni, a member of the Italian Senate, in a recent conference held at Milan at the Circolo Filologico, gave some interesting particulars respecting the actual condition and resources of Tripoli and Cyrenaica. These provinces—he stated—are not the barren and arid lands they are commonly supposed to be by the general public here (Milan), neither is the climate unsuitable for a European population. On the contrary, natural springs and watercourses are abundant, but no attempt is made by the people to utilise them. Artesian wells, tanks, storage reservoirs and irrigation canals are urgently required. In the rainy season the numerous torrents discharge their floods direct into the sea or into the marshes bordering on the coast, uncared for and uncontrolled. By the construction of well-designed hydraulic works, the whole country might be transformed and large areas of land, now unproductive, rendered fertile and productive. The flora in the numerous oases with which the desert is studded is most luxuriant. Many of these like islands in a sea of sand are of considerable extent, and measure several miles across. The value of an oasis is reckoned in Tripoli by the number of its palm trees. Some oases contain as many as 100,000. The roads are merely caravan tracks, which have existed from time immemorial, unkept and uncared for. Works for the improvement of the ports of Tripoli and Benghazi are required urgently. Considerable quantities of dates and olives are exported from the port of Tripoli, chiefly to Malta, Tunis and England. The cultivation of tobacco, under proper fiscal supervision might become a source of considerable

Hosted by Google

revenue to the colony. Tripoli produces oxen, camels and asses, fowls, wool, butter and milk. Game of every description—hares, partridges, quails are plentiful. The tunny and sponge fisheries have also a certain importance. The industries of the country, principally hand-weaving and mat-making are carried on in a very primitive manner. The trade with the interior, across the desert, is declining, although a certain quantity of hides, ivory and ostrich feathers are still brought to the coast by caravans. In Tripoli there are important deposits of sulphur and phosphates. Barley is grown in Cyrenaica, considerable quantities of which are exported to England. At Benghazi, cattle is shipped to Malta and Syracuse, wool to Genoa and Marseilles, and butter to Constantinople. Tripoli and Cyrenaica are sparsely inhabited, and could easily support a population ten times greater than is the case at present.

An Edible Chrysanthemum.—Amongst the numerous varieties of the chrysanthemum cultivated in Japan, there is one which is grown specially for the table. The name of this plant in the language of the country is *Riyori Giku*. The flowers, which are of medium size, yellow or white in colour, are eaten as salad. They require to be boiled, and are said to be much appreciated by the Japanese.

Parcels for Persia.—Attention is directed in Mr. L. Oliphant's report on the trade of Persia, just issued (No. 4796 Annual Series), to the parcel post as a means of extending British trade with Persia. Its advantages are rapidity of arrival in Persia (twenty-one to thirty days from the United Kingdom), and the exemption which it enjoys from Russian customs duties. All other means of communication between Europe and northern and central Persia *via* Russia are handicapped by the fact that no through bill of lading can be obtained for goods passing through Russia, and everything is subject to the ordinary import duty for goods entering Russia, and in addition the Persian customs duties have also to be paid. The parcel post enjoys special treatment in Russia. Parcels for Persia from the United Kingdom cost 3*s.* 9*d.* per 11 lbs. to the Persian frontier, and from there to their destination a charge (fixed by tariff) is levied by the Persian postal administration. Parcels, says Mr. Oliphant, who is Acting Third Secretary to his Majesty's Legation at Teheran, should be packed —on account of the length of the journey and numerous changes of transport—in cases preferably of wood, or wrapped in solid leather (if packed in cloth or similar material the Russian authorities return them to the office of despatch), or they may be packed in zinc or tin hermetically sealed. The latest returns show that the United Kingdom sent 5,296 ordinary parcels and 4,086 registered packets, of the value of £11,099, in 1909; Germany in the same period sending eight times as many ordinary parcels and £11,700 worth of registered goods.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings, at 8 o'clock:—

January 17. — Cyril Davenport, F.S.A., "Illuminated MSS." Sir Walter Armstrong will preside.

January 24.—William J. Gee, "Hydraulic Separating and Grading."

January 31. — Professor G. W. Osborn Howe, "Recent Progress in Radio-Telegraphy."

February 7.—Leonard Hill, M.B., F.R.S., and Martin Flack, M.A., M.B., B.Ch., "The Influence of Ozone in Ventilation."

Indian Section.

Thursday afternoons, at 4.30 o'clock:—

January 18.—The Rev. Walter K. Firminger, B.D., Senior Chaplain, Bengal Establishment, "The Old District Records of Bengal."

February 8. — Colonel Sir Thomas H. Holdich, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc., "The North-East Frontier of India."

March 14.—E. A. Gait, I.C.S., C.I.E., Census Commissioner for India, "The Indian Census of 1911."

April 25.—Walter Saise, D.Sc., M.Inst.C.E., Hon. Member Institute of Mining and Geology, India, A.R.S.M., V.D., "The Coal Industry and Colliery Population of Bengal."

May 16.—Neville Priestley, Managing Director, South Indian Railway, "Indian Railways."

Colonial Section.

Tuesday afternoons, at 4.30 o'clock:—

January 30.—W. A. Legg, M.Inst.C.E., late Supervising Engineer, Irrigation Department, Cape Colony, "Irrigation in South Africa."

February 27.—

March 26.—R. H. Barraut, Resident at Jesselton, "British North Borneo."

May 7.—Alan Burgoyne, M.P., "Colonial Vine Culture."

Cantor Lectures.

Monday evenings, at 8 o'clock:—

Vaughan Cornish, D.Sc., F.G.S., F.C.S., "Ocean Waves, Sea-Beaches, and Sandbanks." Two Lectures.

Syllabus.

Lecture I.—January 22.—The size and speed of ocean waves—The height of waves in lakes, seas, and rivers—The length of waves in lakes, seas, and rivers—The steepness of waves, and strains upon ships—The periodic time of waves, and the rolling of ships—The speed of waves and

Hosted by Google

its relation to velocity of wind—The height of waves and its relation to velocity of wind—The time required to develop large waves, and the duration of storms—The length and speed of the swell observed after storms—The probable height of the swell during storms—The relation between the dimensions and path of a cyclonic depression and the nature of the winds produced—The depth in which waves break, and its relation to defence works.

LECTURE II.—JANUARY 29. — The action of waves and tidal currents on sea-beaches and sandbanks—The proper action of waves to drive sand and shingle shoreward—The proper action of waves to drive mud seaward—Special conditions under which the action on sand is reversed—The proper action of the tide to drive shingle in the direction of the flood—The normal removal of shingle from promontories and its accumulation in bays—The exceptional accumulation of shingle in salient positions, *e.g.*, at Dungeness—Groynes—The reason of the graded arrangement of shingle on the Chesil beach—The formation of a sandbank on the up-channel side of a promontory—Sandbanks in estuaries and their arrangement by tidal currents—Their rippled surface as a means of mapping these currents—Their influence on the formation of tidal bores—The struggle between land water and tidal water to arrange the sandbanks in the Severn—The variability of the Severn Bore as determined by these factors—The circumstances which determine the starting point of the Severn Bore.

LOUDON M. DOUGLAS, F.R.S.E., "The Meat Industry." Three Lectures.

February 5, 12, 19.

LUTHER HOOPER, "The Loom and Spindle: Past, Present, and Future." Three Lectures.

February 26, March 4, 11.

NOEL HEATON, B.Sc., F.C.S., "Materials and Methods of Decorative Painting." Three Lectures.

March 18, 25, April 1.

HOWARD LECTURES.

Monday evenings, at 8 o'clock:—

CAPTAIN H. R. SANKEY, R.E., M.Inst.C.E., "Heavy Oil Engines." Four Lectures.

April 29, May 6, 13, 20.

Dates to be hereafter announced:—

H. A. ROBERTS, M.A., "The Relations of Science to Commerce and Industry."

CECIL THOMAS, "Gem Engraving."

F. MARTIN DUNCAN, "The Work of the Marine Biological Association."

JOHN NISBET, D.Oec., late Conservator of Forests, Burma, "The World's Decreasing Timber Supplies."

FRANK WARNER, "Silk."

CHARLES C. ALLOM, "The Development of Artistic Skill in the Applied Arts."

ERNEST KILBURN SCOTT, Assoc.M.Inst.C.E., M.I.E.E., "The Manufacture of Nitrates from the Atmosphere."

CHARLES BRIGHT, F.R.S.E., M.Inst.C.E., M.I.E.E., "The Administration of Imperial Telegraphs."

HAROLD COX, "The Interdependence of Morals and Economics."

E. D. MOREL, "British Rule in Nigeria."

GORDON CRAIG, "Art of the Theatre." MISS ELLEN TERRY will preside.

THEODORE E. SALVESEN, "The Whaling Industry of To-day."

PROFESSOR ERNEST A. GARDNER, M.A., "Greek Sculpture."

GEORGE FLETCHER, "Technical Education in Ireland."

MEETINGS FOR THE ENSUING WEEK.

MONDAY, JANUARY 1...London Institution, Finsbury-circus, E.C., 4 p.m. (Juvenile Lecture.) Mr. F. Martin Duncan, "In Neptune's Kingdom, or the Wonders of Life in the Sea." (Lecture I.)

TUESDAY, JANUARY 2...Royal Institution, Albemarle-street, W., 3 p.m. (Juvenile Lecture.) Dr. P. Chalmers Mitchell, "The Childhood of Animals." (Lecture III.)

WEDNESDAY, JANUARY 3...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5 p.m. (Juvenile Lecture.) Mr. C. Vernon Boys, "Soap Bubbles." (Lecture I.)

London Institution, Finsbury-circus, E.C., 4 p.m. (Juvenile Lecture.) Mr. F. Martin Duncan, "In Neptune's Kingdom, or the Wonders of Life in the Sea." (Lecture II.)

Builders, Koh-i-Noor House, Kingsway, W.C., 4 p.m. Mr. A. W. Gattie, "How to Cheapen Transport."

THURSDAY, JANUARY 4...Royal Institution, Albemarle-street, W., 3 p.m. (Juvenile Lecture.) Dr. P. Chalmers Mitchell, "The Childhood of Animals." (Lecture IV.)

FRIDAY, JANUARY 5...Geographical, Burlington-gardens, W., 3 p.m. (Juvenile Lecture.) Mr. Julian Grande, "Among the Alps."

London Institution, Finsbury-circus, E.C., 4 p.m. (Juvenile Lecture.) Mr. F. Martin Duncan, "In Neptune's Kingdom, or the Wonders of Life in the Sea." (Lecture III.)

Geologists' Association, University College, W.C., 8 p.m. 1. Messrs. R. H. Chandler and A. L. Leach, "On the High Terrace Gravel and on a Palæolithic Implement Factory, Dartford Heath." 2. Mr. A. L. Leach, "On the London Clay and Bagshot Beds (Passage Beds), and on the Gravel of Shooter's Hill, Kent."

SATURDAY, JANUARY 6...Royal Institution, Albemarle-street, W., 3 p.m. (Juvenile Lecture.) Dr. P. Chalmers Mitchell, "The Childhood of Animals." (Lecture V.)

Hosted by Google

Journal of the Royal Society of Arts.

No. 3,085. VOL. LX.

FRIDAY, JANUARY 5, 1912.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

WEDNESDAY, JANUARY 10th, 5 p.m. (Juvenile Lecture.) CHARLES VERNON BOYS, F.R.S., "Soap Bubbles." (Lecture II.)

The lecture will be illustrated by numerous experiments.

Further particulars of the Society's meetings will be found at the end of this number.

LIST OF MEMBERS.

The new edition of the List of Members of the Society is now ready, and can be obtained by Members on application to the Secretary.

COVERS FOR JOURNALS.

For the convenience of Members wishing to bind their volumes of the *Journal*, cloth covers will be supplied, post free, for 1*s*. 6*d*. each, on application to the Secretary.

JUVENILE LECTURES.

On Wednesday afternoon, January 3rd, Mr. CHARLES VERNON BOYS, F.R.S., delivered the first lecture of his course on "Soap Bubbles."

After showing how simple it is to blow a soap bubble, and what a beautiful object it is, Mr. Boys explained that the bubble afforded means for making experiments and obtaining valuable nformation in many branches of physical science, and that it afforded most elegant illustrations of difficult branches of mathematics. He hoped to show them many experiments which could not fail to be beautiful if they succeeded, and which illustrated in a pleasing way a considerable variety of physical actions and principles.

Water was shown by a series of experiments to have an elastic "skin"; its surface was stretched with a definite force of a little over three grains to the linear inch. This is made use of by spiders and insects in their daily existence. Other liquids show a similar elastic skin, which, however, except in the case of melted metals, is not so strong. The "tears of wine," and the movements of other liquids due to this cause, were shown. In the case of liquids which do not mix, movements also result; such, for instance, as the spreading of oil on water leading to the stilling of troubled waters.

In the case of soap solution, the strength is only about one-third that of water, and this and the slight variations of the strength due to varying surface concentration, are the reasons why a soap bubble can be blown at all. This is because the skin is weak, not because it is strong. Pure water, which is the strongest transparent liquid in this respect, does not allow bubbles to be blown.

The strength of a soap film was shown by experiments, and the contrast of a soap bubble and a saponine bubble exhibited. The considerations of stability as well as strength were touched upon, and the question was illustrated by means of an experiment with an egg-shell held by a soap film so as to rest upon the edge of a rim, but always so that its greatest cross section lay in the plane of the film. It could then roll or roll and jump when the rim was turned round, but the film prevented it from escaping.

Another illustration of stability was shown, where a spherical bubble blown with oxygen gas, and placed between the poles of an electromagnet, did not show any action of the magnet on the feebly magnetic oxygen, as the spherical bubble was too stable. On drawing this out

Hosted by Google

into a cylindrical form, very nearly as great in length as it was in circumference, a condition in which it is nearly unstable, the turning on of the electric current instantly caused the bubble to separate into two, the larger one being between the poles of the magnet.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

THE CARBONISATION OF COAL.

By Vivian B. Lewes,
Professor of Chemistry, Royal Naval College, Greenwich.

Lecture III.—Delivered December 11th, 1911.

The Thermal Conditions Existing during the Carbonisation of Coal.

Having gained an idea of the results desired in the manufacture of illuminating gas and furnace coke, we can pass on to the thermal conditions existing during carbonisation, and at the outset we are met by the difficulty that little is known as to the heat of formation of coal, and that a variety of opinions exists on this point.

It is evident that, as the composition of coal in a mine will vary not only in different seams but even in the same seam, there is no definite composition, and that nothing can be known as to the heat of formation except by direct determination, which necessitates experimental estimations of so complicated a nature that the introduction of errors is extremely likely to vitiate the results.

Probably the most valuable work done in this direction is to be found in a report presented by M. Euchêne on the thermic reactions which occur during the distillation of coal, given in the Transactions of the International Gas Congress in Paris, 1900, in which he determines the thermo-chemical data coming into play during the distillation of coal in the manufacture of gas, with careful estimations of the heat of formation of the products of the distillation as compared with the heat developed by the fuel needed for the distillation; that is to say, a balance is struck, showing on the one side the heat generated, and on the other the heat expended, the difference found representing the heat of the decomposition of coal.

Mahler also determined the calorific value of a coal and of the products obtained on carbonising it, and both these observers found that the calorific value of the coal exceeded that of the products, that is, that coal is endothermic, and that its decomposition evolves heat; but it is quite clear that in the determination of a factor of this kind, which is dependent upon the difference between two figures obtained from a highly-complicated set of determinations, each with its own source of error, and all tending in the same direction, these will be borne by the resultant, and it is not surprising, therefore, to find that with a coal of the same type Mahler found the heat of decomposition to be + 254·83 calories, whilst Euchêne found it to be + 63·51 calories.

In Mahler's work, the result was arrived at by deducting the heat of combustion of the products from the heat of combustion of the coal, whilst Euchêne's determinations were obtained by taking the difference between the heat supplied and the heat consumed during distillation, so that the difference between these two would be likely to be increased by errors leading in opposite directions.

M. Euchêne has determined in this way the heat liberated during the distillation of three types of coal, these results showing in a striking way that the heat liberated increases in nearly regular ratio with the amount of volatile matter in the coal, and that the more oxygen the coal contains the more endothermic its reaction, a fact which points clearly to its being the oxygen-bearing compounds in the coal which give it its endothermic character.

M. Euchêne, in his experiments, obtained results which may be tabulated as follows:—

Moisture.	Ash.	Carbon.	Hydrogen.	Oxygen.	Volatile Matter.	Heat of Formation. Calories.
2·70	7·06	77·56	4·79	5·94	25·99	+ 12·39
3·31	7·21	76·00	4·78	6·82	28·30	+ 35·98
4·34	8·18	72·08	4·78	8·73	32·17	+ 63·51

It is well known that if a coal be carefully analysed, and its thermal value is then determined in a bomb calorimeter and compared with the thermal value as calculated from the most generally accepted formula from the analysis, the results will be in very good accord as long as one deals with an anthracite or steam coal low in oxygen content, but that directly there

Analysis of Coals (Dry) and Calorific Value.

Coal.	C.	H.	S.	Ash.	O.+N.	Fixed Carbon.	Volatile Matter.	Calorific Values. Calculated.	Calorific Values. Determined.	Difference taken as Heat of Formation. Calories.
A.	90·09	3·85	0·77	1·68	3·61	91·48	6·84	8567	8629	62
B.	81·02	3·23	0·64	9·50	5·61	80·80	9·70	7527	7713	136
C.	87·79	4·09	0·59	3·14	4·39	82·79	14·08	8425	8617	182
D.	84·07	4·51	0·68	5·69	5·04	73·81	20·50	8241	8394·5	153·5
E.	78·29	4·76	1·48	4·90	10·57	61·10	34·00	7638	8026·5	388·5

is any large amount of oxygen, and therefore highly volatile matter in the coal, the value as determined rapidly rises above the calculated value.

Now, in the calculation, it is presumed that all the hydrogen is in combination with oxygen to form water, so that its heating value is lost to the coal, whilst we know that if coal is decomposed we obtain large volumes of free hydrogen, and that unless the temperature of decomposition is very low, but little water is formed, and the secondary product (tar) contains most of the oxygen as oxygenated hydrocarbons; that is to say, the complex character of the oxygen compounds in the coal and the way in which they break up renders the calculation of thermal value too low.

If this were not so, it might be possible to determine the degree of endothermicity of a coal in this way, and it is interesting to see how figures so obtained agree with those put forward by Mahler and Euchêne.

Brame and Cowan made careful analyses of five samples of dried coal in duplicate, the mean of two analyses of each being taken. Three determinations of the calorific value of each coal in the Mahler bomb were then made, and these being in close agreement the mean of the three tests was taken in each case (see table above).

Now we know that the heat of formation as deduced from these figures will be too high, as the calculation errs on the low side, so that the true heat of formation will be slightly below this value, and we can use this as a rough guide to forming an opinion as to the correctness of Mahler's and Euchêne's figures.

Euchêne found that a coal containing 8·73 per cent. of oxygen and 32·17 per cent. of volatile matter, had a heat of formation of 63·51 calories (114·3 B.Th.U.), whilst Mahler, for the same class of coal, found 254·83 calories (458·7 B.Th.U.), so that Mahler's figure is in accord with that deduced for a coal intermediate between coals E and D as analysed by Brame and Cowan, and is probably a little too high.

Constam and Kolbe made a very fine research upon the carbonisation of typical English coals in 1909,* and determined their calorific value, and also the calorific value of their distillation products, and found that the value of the coal exceeded the heat value of the products to the extent shown in the table given below, in which the heat balance of the products of distillation of the ash-free and dry coal is given in percentages of the heat value of the coal substance.

This shows, as in the other determinations given, that when we get down to a steam coal, *i.e.*, a coal poor in volatile matter and oxygen, its calorific value more nearly approaches that obtained by calculation or by determination of the heat present in the products.

If we now take the Low Main, Barnsley and Hutton Seam coal, and calculate what the loss of heat shown in the table amounts to per

	Description of Coal.	Heat found in Coke.	Heat found in Gas.	Heat found in Tar.	Heat found in Pitch.	Loss of Heat.

Hosted by Google

pound of ash- and water-free coal, we obtain the following results:—

	B.Th.U. per lb.	Loss per cent.	B.Th U.
Low Main . .	15,393	4	615·68
Barnsley . . .	14,792	2·5	369·80
Hutton . . .	15,766	2·9	457·21

and the average of these results would be 480·9 B.Th.U. per pound, and if we take this as due to the endothermicity of the coal, the figure agrees with Mahler's determination, and also with the figure deduced from Brame and Cowan's work.

It seems likely that when the oxygen in the coal falls below 3 per cent., all endothermicity will disappear, or at any rate become negligible, whilst with gas coals of the type most used in England, containing about 32 per cent. of volatile matter and 7 to 8 per cent. of oxygen, it will approximate to 250 calories or 450 B.Th.U. per pound of coal; but all the evidence as to this property in coal is of an unsatisfactory character.

The thermal value of the reactions in the retort will remain the same whether the distillation be carried out in a horizontal, vertical, or inclined retort, in a coke oven or a chamber, and it is chiefly in the setting that the economies have been made which have reduced the carbonising fuel to the figures attained in modern practice.

In the horizontal retort setting quoted above the total heat used would be 1228 + 1884 = 3112. Now, 1 lb. of gas coke gives an average of 14,200 B.Th.U. in its combustion, so would give enough heat to carbonise 4·5 lbs. of coal, or, in other words, the coal would require 21·9 per cent. of its weight of coke to carbonise it, whilst, if the whole of the heat of combustion could be used in the retort, 8·6 per cent. would be sufficient.

A fair idea of the economies that are possible can be obtained by stating the heat used in the setting and retort in percentages:—

		B.Th.U. per lb.	Per cent. of heat used.	
Used in retort	1. Decomposition and distillation	462	15·7	39·3
	2. Escaping in gas and vapours	324	10·4	
	3. In hot coke	442	13·2	
Used in setting	1. Flue gases	1463	47·2	60·7
	2. Radiation and convection	398	12·8	
	3. Ash	23	0·7	

When a coal is carbonised it decomposes into gases and vapours, leaving behind the solid coke, and heat is used up in bringing about the change of state. When 1 lb. of coal is decomposed in the retort the heat used up in the decomposition and distillation amounts to 462 B.Th.U. over and above the heat due to endothermic reactions. The heat withdrawn from the retort by the hot gas and vapours amounts to 324 B.Th.U., and the heat in the red-hot coke when it is drawn accounts for another 442 B.Th.U., so that the heat that has to be actually supplied for the carbonisation is 462 + 324 + 442 = 1228 B.Th.U.

The losses in the setting, however, exceed this, and in an ordinary horizontal bench would be 1,463 B.Th.U. escaping with the flue gases, 398 B.Th.U. lost to the air by radiation and convection, and 23 B.Th.U. in the ash, making in all 1,884 B.Th.U.

so that 39·3 per cent. of the heat is used in the retort, and 60·7 in the setting, the item which overshadows all others being the 47·2 per cent., which escapes up the chimney in the hot flue gases.

It is evident that the first step towards economy is to be found in a better utilisation of the heat in the setting, so as to abstract as far as possible the heat from the products of combustion, and this is done by regeneration, which reduces the flue gases by over 300° C. in temperature, and brings down the loss due to this item from 47·2 to 25·2 per cent., whilst feeding the producers with red-hot coke from the retorts effects a further economy, with the result that the fuel used falls from 21·9 to 14·8 per cent., and even lower.

Under these conditions the percentage of heat used in doing the work of carbonisation would be largely increased, and the chart would be as follows:—

Used in retort	1. Decomposition and distillation	21·4	54·1
	2. Escaping in gas vapours	13·8	
	3. In hot coke	18·9	
Used in setting	1. Flue gases	25·2	45·9
	2. Radiation and convection	19·9	
	3. Ash	0·8	

Hosted by Google

so that over one-half the heat is utilised in work.

In the most modern practice, results as low as 10·24 per cent. of the weight of the coal carbonised have been quoted, whilst in vertical retorts and chamber carbonisation 12 to 15 per cent. is the usual figure, these advances being made by utilising hot coke in the producers, more perfect regeneration, and reduction of the radiation.

The factor which endows all carbonisation problems with especial difficulty is that we are dealing with a body of such varying composition that no two samples are alike, whilst the conditions under which we are decomposing them vary from minute to minute.

The conduction of heat through a substance like the walls of a fireclay retort is a determination fraught with many troubles, as the conditions existing in a retort heated in a bench are totally different from those that can be obtained in making experimental determinations in a laboratory. In any calorimetric determination the one side of the test piece is continuously cooled by the calorimeter, whilst the heat poured into the other side is very different in effect to the mass of heated material existing in the flues surrounding the working retort.

The rate at which heat is transmitted under working conditions depends upon the degree of heat in the flue and outer walls of the retort, the higher the temperature the more rapid being the transmission, whilst the difference between the temperature of the outer and inner skin of the retort is a factor of the greatest importance. The greater the difference—*i.e.*, the cooler the inner skin and the mass in contact with it, and the hotter the outer skin in the flue—the more rapidly will the heat pass. Again, the rapidity of transmission varies with the character of the fireclay, with its porosity, and with the temperature and length of time for which it has been baked, so that it is impossible to give any definite figure as to the rate of conductivity or transmission which shall hold good in all cases. Determinations based upon the rate of transmission at comparatively low temperatures may be discarded at once as valueless; but Mr. G. Beilby determined the conducting power of firebrick, and came to the conclusion that one square foot of firebrick, one inch thick, passed 6·59 Centigrade pound units, or 11·86 B.Th.U. per hour for each degree Centigrade of difference between the sides of the brick, when these differences were of the magnitude of 200°–300° C.

S. Wologdine has also determined the rate of conductivity of fireclay, and finds that the heat transmitted through a thickness of 1 metre across an area 1 square metre per hour for a difference of 1° C. varies from 1·07 calories, when the clay has been baked at 1050° C. (1922° F.), to 1·81 calories, when it has been baked at 1300° C. (2372° F.), and that the diagram connecting fall in temperature with thickness of material is a straight line.

My own opinion is that, at the ordinary working temperature of a retort under gasworks conditions, the amount of heat transmitted approximates to 25 B.Th.U. per square foot of surface for each 1° C. difference in the temperature of the outer and inner surface of the retort, and that this is not seriously affected by the thickness of the fireclay, as conduction is so slow with a retort 3 ins. thick that it is probably only the internal portion that is cooled to any great degree when a fresh charge is fed into a properly heated retort, and the mass of fireclay acts as a store of heat, so that the heat has only a short travel.

In a horizontal retort ready for charging, the temperature of the inner walls will approximate to 1000° C. (1832° F.), and the flue temperature to 1100° C. (2012° F.), and the fireclay walls of the retort will conduct the heat at a rate which approaches to 25 B.Th.U. per square foot for each degree Centigrade difference in the two surfaces per hour, so that during the first two hours, when the average temperature of the inner side of the retort walls, cooled by the charge and by the retort having been opened, will not be more than 800° C. (1472° F.), the amount of heat passing through the walls into the charge will be 25 × (1100 – 800) × 7500 B.Th.U. per square foot of surface, whilst by the fifth hour, when the inner side of the wall of the retort has risen to 950° C. (1742° F.), the amount passing will be 25 × (1100 – 950) = 3750 B.Th. U., or only half the amount passed in the earlier period, the average being approximately 5,625 B.Th.U. per hour, which, taking the heat units needed for the actions taking place in the retort as 1,228 B.Th.U. per lb., gives a carbonising value for a six-hour charge of 12 tons per 1,000 square feet of retort surface.

The diminution in the quantity of heat passing through the walls of the retort during the last stages of carbonisation does not affect the rate at which the still uncarbonised core of coal is being heated, as the envelope of coke surrounding it has reached nearly the same temperature as the walls of the retort, and forms a store of heat, whilst in the carbonising

mass during the first part of the distillation the volume of gas evolved is so large that it carries off from the contents of the retort a large proportion of the heat, and so keeps down the temperature of the mass until the later stages of the carbonisation.

It has become the custom to speak of the temperature of carbonisation being high merely because the temperatures in the flues and in contact with the walls of the retort are high, and to speak of the products of high temperature distillation as if the coal had been carbonised at the temperature existing on the retort surface.

It is quite clear, however, that, coal being a bad conductor of heat and coke a worse one, it is only the layer of probably less than an inch thick that is carbonised at anything like the retort temperature, and that the remainder of the charge is distilled at a slowly rising temperature, which attains its maximum only after the volatile products have been practically all driven off.

The real distinction between high heats and lower flue temperatures is that the higher the temperature employed the thicker and hotter will be the layers of coke which the gases and vapours have to traverse in their escape from the inner portions of the charge, and the greater will be their exposure to radiant heat and contact with the highly heated surfaces of the retort in their outward passage from the carbonising mass; the products of the primary action are, in fact, being subjected to secondary decomposition under conditions we neither know nor can control, and this is one of the weakest points in our methods of carbonising for the production of illuminating gas.

We make elaborate tables of the composition of gases and tars produced at various distillation temperatures, but the only information that they give us is what is left undecomposed under unknown and varying conditions, the only certain factor being that the heat was nowhere above that which we are pleased to call the temperature of distillation.

It is evident that if these variations exist in the temperature at which the coal is distilling in the comparatively small charge in the gas retort, they must be accentuated when one comes to deal with carbonisation in bulk as practised in oven and chamber settings, as not only is the travel of the gases and vapours through the red-hot coke much longer, but the rate at which the heat is conducted through the carbonising mass becomes slower as the bulk of the charge increases, whilst the temperature in the crown of the oven during the first half of the time is higher than is found in the gas retort, and this also applies to the temperature in the top layer of the coke.

If the coal is carbonised in a 6 in. diameter tube, filled so that the heat shall be penetrating from every side, there is an almost immediate rise in temperature throughout the mass, owing to the hot gases and vapours passing through the interstices between the pieces of coal, and the coke attains its maximum temperature at the rate of about one inch per hour, so that in three hours, with a wall temperature of 1000° C., the centre of the mass would be at about 950° C., and the carbonisation would be finished. If, however, the tube be increased to 12 ins. in diameter, the rate of conduction is reduced to 0·5 in. per hour, and the same thing takes place with a flat-chamber retort heated from the sides, so that it would take about twelve hours to complete the carbonisation, whilst with further increase in the width of the chamber the rate of travel of the heat grows still less, the passage of the heat being still slower as the distance between the walls of the chamber gets greater.

The result of this is that in by-product recovery coke ovens, and large chamber retorts, the period of carbonisation becomes very long, and the gas has to pass through so much hot coke that the illuminating power is reduced to nine or ten candles.

These rates of passage of heat apply only to vertical retorts or chambers, the sides of which are heated, as bottom heat penetrates the mass rather more quickly owing to convection coming to the aid of conduction, and the upward flow of heated gases raising the temperature in advance of the conducted heat.

Moreover, the rate at which the heat travels in the carbonising mass depends to a great extent on the initial temperature employed, the figures given being attained only when the flues and outer walls of the retort or chamber are heated to about 1100° C. (2012° F.), but if the flue temperature is lowered the transmission of heat becomes lower, and a longer period, therefore, is required for the complete carbonisation; so that if in a 6 in. tube with a wall temperature of 1000° C. (1832° F.) it takes three hours to complete carbonisation, it would take six hours to do the same work with a wall temperature of 500° C. (932° F.). Consequently, in making low temperature coke, such as coalite, in tubular retorts 5½ ins. to 6½ ins. diameter, it takes four hours to drive off two-thirds of the volatile matter that is in the coal.

Hosted by Google

The temperature of the coke or coal through which the gas and tar vapours have to pass, and the length of travel they have in reaching the exit from the retort or chamber in which carbonisation is proceeding, are two of the most important factors in determining their decomposition, as it is these which give rise to the secondary reactions that largely determine the final composition of the gas and tar.

Valuable pyrometric observations on the temperatures existing in charges of varying size have been made by Mr. Bond, of Southport, and other observers, from whose work we can deduce the following results as typical.

If an ordinary D-shaped horizontal retort, 18 ins. to 20 ins. wide and 15 ins. high, has a 6 in. charge fed into it, the space from the apex of the crown to the top of the charge will be 9 ins. deep. If now thermo-couples properly protected are placed—(1) at the bottom of the charge, (2) in the centre, and (3) at the top of the charge, we can gain a good idea of the way in which the heat is acting on the coal.

With full heats the coal at the bottom of the retort rapidly heats up, and in fifteen minutes has reached 700° C. (1292° F.), after which its rise in temperature slows down, and it takes two hours to reach 800° C. (1472° F.); after this it heats more rapidly, and attains 1000° C. (1832° F.) at the end of four hours, and then there is practically no rise in the last two hours of carbonisation. The temperature at the top of the charge rises more slowly, and by the end of the second hour is only 740° C. (1364° F.), or 60° cooler than the bottom, and remains at a lower temperature throughout the whole carbonisation. This is not to be wondered at, as although the top flue of the setting is 1150° C. (2102° F.), and the bottom flue barely 1100° C. (2012° F.), the coal at the top of the charge is being heated largely by radiant heat acting across a considerable gas space, whilst the bottom of the charge is in direct contact with the heated bottom, and is taking in heat by conduction.

The thermo-couple in the centre of the charge throws most light upon the course the distillation is taking, and we discover that so great is the heating effect of the gases and vapours passing up from the hot zone at the bottom of the retort, that at the end of the first hour the temperature is only 30° below that of the bottom, 730° C. (1346° F.), whilst in two hours it is at the same temperature, and then falls slightly below it for the rest of the time, the rush of hot gases from the bottom having ceased, and the temperature of the top of the charge equals the centre only after the fourth hour.

Now the fact that differences in temperature are so small throughout the mass, and that during the whole of the period when the bulk of the gas is being evolved the centre of the charge is hotter than the top, points to the gas forcing its way through the pasty mass of distilling coke upwards into the space below the crown of the retort, where it is baked by radiant heat from the mass of fireclay at 1050° C. (1922° F.), and the retort walls at 1050° C., and the coke at from 700° to 1000° C. (1292° to 1832° F.), are also in surface contact with it.

The passage of the gas through the pasty coke causes considerable swelling during the first hours of distillation, and when the shrinkage in the charge of coke takes place during the last two hours, the top portion, presumably carbonised by radiant heat from the top of the retort, shrinks over a smaller depth than the bottom and large portion, so that when the charge comes to be drawn there is found to be a fissure running horizontally between the upper and lower portions, but nearer to the top, from which vertical cracks branch to the top and bottom of the charge.

We are at present dealing only with the thermal conditions existing during carbonisation, but when we come to study the more chemical side of the actions taking place, we shall see that such methods are the most brutal form of distillation—high heats and small charges certainly mean high makes of gas, but got at the expense of all the other by-products, and bringing in their train all the troubles of stopped ascension pipes, carbonised retorts, ruined tar, and poor coke. If, instead of using a 6 in. charge in such a retort, it be filled with coal as nearly as a horizontal retort can be filled—that is, to within two or three inches of the apex of the crown of the retort, and the same temperatures as before are used in the setting, you approach to the same conditions that obtain in vertical retorts, which are entirely filled, and quite different results are obtained.

The improved results are by most observers ascribed to the doing away with the baking chamber above the charge, radiant and contact heat being credited with the formation of free carbon and naphthalene, which have been the chief curses that have accompanied the raising of temperatures with small charges to increase the gas volume obtained.

The determination of temperature as before in the charge shows that filling the retort does

Hosted by Google

a great deal more than this, however. In the first place, in order properly to carbonise the charge, the heating has to continue from eight to twelve hours, instead of six, and the heat is poured into the charge in a much more even manner, the rise in temperature at both top and bottom being equal throughout the distillation, and with the top temperature always about 100° C. more than the bottom, truly reflecting the difference in temperature between the top and bottom flues of the setting. Owing to the thickness of the charge having been doubled, the heat advances more slowly into the mass, rendering the coal semi-fluid and pasty in front of it, and so forming the whole centre of the charge into a tube through which a large proportion of the gas finds its way down to the mouth of the retort without having been overheated in the crown.

That this is the true explanation is shown by the thermo-couple in the centre of the charge, which during the first five and a half hours of the distillation rises slowly in temperature at about the same rate as the outer portions, but on a plane 500° C. (932° F.) below them, whilst after this period the central heat rises rapidly, and the same temperature as exists at the bottom of the charge is attained in the eighth hour.

The gas is improved, because only a small portion has to run the gauntlet of overheating; the tar is improved, because a considerable proportion is made at a lower temperature; the coke is improved, because in the earlier half of the distillation a good deal of tar has condensed in the cool zone, and as the temperature rises the more volatile portions redistil, but the least volatile remain and get decomposed only in the last hour of carbonisation, increasing the gas yield, the factor for which the gas-manager at the present time seems prepared to make any sacrifice.

It must be clearly borne in mind that the possibility of filling a horizontal retort to within three inches of the crown, although suggested by Kunath in 1885, is a comparatively new condition, which could only be achieved by the introduction of discharging machinery that would push the charge of coke out of the retort, and that as long as we were dependent upon hand labour to draw the charge it was impossible. Now, however, the introduction of vertical settings allows a more complete filling of the retort by gravity, and easy discharge, so that the question of the route taken by the gas in its escape from the carbonising mass is receiving its full share of attention, and opinions on the subject are by no means unanimous.

Dr. Bueb, to whom we owe the inception of the Dessau vertical retorts, is strongly of opinion that the largest bulk of the escaping gas finds its way through a cool core in the same way that it undoubtedly does in a well-filled horizontal retort; others favour the theory that the major portion passes up the sides, whilst Dr. Harold Colman and many others agree that as the pasty area of the decomposing coal works its way inwards from the walls of the retort to the centre, gas escapes on both sides of it, so that a portion goes up the centre and the remainder through the hot coke or up the walls of the retort. What proportions exist between the gas that takes the cool route and that which is forced to pass through the hot coke cannot be exactly determined, and would vary with every kind of coal, but what we do know beyond doubt is that a large volume of the richest gas comes off from all coals when first heated, so that a large evolution of primary gas will be on the inside of the tube of semi-fused coal, whilst another factor, which would tend to make the gas take the inner route, is that any passing back into the hot zone would be expanded by the temperature, whilst the still pasty coke would offer more resistance to the passage of the gas than the coal, so that pressure would be highest on the hot side and lower on the cool, the probabilities, therefore, being that as long as the central passage is unimpeded the major portion of the gas passes up the centre. The analyses of the gases, however, all show that far too much cracking of the rich hydrocarbons has taken place.

I have had a considerable experience in carbonisation in vertical 5½ in. to 6½ in. tubes at all temperatures, and find that for a considerable period the gas escapes freely up the central core, but a time soon arrives with a column of this thickness in which the least volatile constituents of the tar condense in the central core, and so choke it that the pressure rises to an undue degree in the lower half of the tube, and causes serious leakage at the bottom door of the retort, whilst some gas and tar vapours are forced from the lower half of the charge through the already choked portion and along the walls, and as pressure is the most fertile source of carbon deposits in a retort, this is a serious consideration.

When we are dealing with a well-filled horizontal retort, we have an oblong mass of coal, 18 ins. to 20 ins. wide by 12 ins. thick, and the heat advances so slowly that there is but little fear of choking from tar until the distillation is practically nearly completed, and the same thing

Hosted by Google

will be found with chamber retorts, such as have been installed by Mr. Thomas Glover at Norwich. These latter consist of oblong retorts, 3 ft. high, 1 ft. wide, and 21 ft. long, taking 21 cwt. of coal as a charge, which requires twelve hours for its proper carbonisation. In these chambers the course of the heat is manifestly inwards from the sides, which constitute the largest heating area, as is shown by the fracture of the coke on drawing being vertically down the centre. It has been seen that with the horizontal retort the coke on drawing has a horizontal fissure or fracture through the mass, the heat having passed into the charge chiefly from the top and bottom. The fracture in a coke charge is due to tar distilling forward before the advancing heat in the charge, and portions condensing at the coolest spot to be afterwards redistilled as the heat reaches that area of the charge. This takes place during the last two hours of the carbonisation, during which time the remainder of the coke is contracting and becoming denser under the prolonged action of heat, which shows itself by the charge shrinking from the walls, and also from the still soft central layer, leaving the fissure in the finished coke. When the carbonisation is carried out in a tube, the fissure becomes a hole in the centre of the rod of coke, the sides of the hole showing ample signs of the carbonised tar, whilst, if forced from the tube two hours before carbonisation is completed, the core is found to consist of coal and soft pitch.

In coke ovens, in which a large mass of coal is heated from the sides, the fissure (or plane of separation, as it is best called, to distinguish it from the planes of cleavage, which as a rule are nearly at right angles to it) is vertically down the centre when the oven has been properly heated, and the two sides are at the same temperature; but if the two sides are not at the same temperature, the plane of separation is found nearest to the cooler side.

There is a wide difference between coals of very much the same ultimate composition in the way in which they are affected by heat during carbonisation, and the value of the coke produced will largely depend upon the conditions of carbonisation being made to fit the behaviour of the coal—a point to which sufficient attention has not yet been paid in the manufacture of coal gas.

This has made itself felt in the introduction of the vertical retort, in which it is found that certain classes of coal give rise to undue swelling of the charge in the earlier stages of carbonisation, and so lead to choking of the top of the retort.

When horizontals with a 9 in. space above the coal were used it did not matter how much or how little the coal swelled, but with a completely filled vertical retort it becomes a serious matter.

The swelling of a coal during destructive distillation is largely dependent upon its degree of fusibility. If a coal fuses easily, and the products are fairly liquid, the gases escape from it readily by the bursting of the tar bubbles formed, and the swelling is but slight. So also infusible coals, which undergo but little softening, give no trouble in this respect, but coals which yield a tough viscid mass form large bubbles, and give rise to troublesome swelling, which shows itself even more with low temperature carbonisation than with high heats, and this was one of the factors that gave serious trouble in the manufacture of "coalite."

In the manufacture of coal gas in lightly-charged horizontal retorts, not only does the length of travel that the escaping gases have to undergo through red-hot coke vary through the whole process, but the length of time they are exposed to radiant heat in the crown of the retort, and the amount of contact with the highly-heated fireclay surface, also vary to an extent that makes any uniformity of action or result an impossibility.

The products of distillation from the coal near the mouth of the retort, be it horizontal, vertical or sloper, have only a short travel to reach the mouthpiece, and are hurried on by the gas behind them, so that the time given for secondary reactions is curtailed to a fraction of a second, whilst the gas from the end of the retort has nothing to drive it forward, and has to run the gauntlet of surface action and baking to an extent that results in little else than hydrogen and carbon. Between these two limits every degree of secondary reaction is to be traced, and the gas and tar obtained are a mixture of the results of everything from low temperature distillation for a short period to high temperature for a long period.

The temperature of the gas as it reaches the mouthpiece of the retort shows but little of these variations in individual portions of the gas, as they are going on *pro rata* throughout the whole time of carbonisation, and the thermo-couple or thermometer registers merely the mean temperature of the volume of escaping gas, so that as the period of carbonisation proceeds, and the bulk of distilling gases and vapours grows

Hosted by Google

smaller, the temperature of the escaping products grows less, although coming from a mass at a higher temperature.

It will be found that at the usual carbonising heats, as soon as the gas begins to escape freely, the temperature at the mouthpiece will be approximately 400° C. (752° F.), and that this will remain fairly constant until the fifth hour, whilst the falling-off in volume during the fifth and sixth hours is reflected by a gradual fall in temperature of about 100° C. (180° F.). As might be expected, the slowing down of the rate of flow of gas and vapour is shown even more by the temperature at the top of the dip-pipe, which rises with the first rush of gas to 120° C. (248° F.), and then steadily falls to about 50° C. (122°F.) by the end of the period of carbonisation.

In the secondary reactions taking place in the retort, pressure plays an important part, and as pressure is being created constantly by the evolution of gas, expansion and decomposition, the maintenance of an even pressure is a matter of great difficulty, and where the dip-pipe and hydraulic main are used, although the retort-house governor may keep the pressure steady in the hydraulic main itself, the escaping gas will be subjected to "throbs" of pressure as the gas forces out the liquid in the dip and escapes into the hydraulic main. When the gas is escaping rapidly, these changes of pressure succeed each other so rapidly that the effect in the retort is a pulsation, whilst as the flow of gas slows down the individual "throbs" become more and more distinct, and short as their duration may be, they add to leakage and to decomposition.

In many works little or no attention is paid to the size of coal used, and the coal as it comes from the truck, barge, or ship goes into the retort, only the lumps so large as to give trouble being broken, and it is manifest that the flow of heat into the mass must be considerably affected. Indeed, in the manufacture of furnace coke uniformity in size in the coal is looked upon as being as important as amount of moisture and other factors of the same kind.

It is clear from these considerations that in the destructive distillation of coal for the manufacture of gas there is no one factor of uniformity in any part of the process, and that to attempt to trace the course taken in the decomposition of a body of unknown structure like coal under such conditions is not likely to meet with much success.

Many observers have attacked the problem of distilling coal at various temperatures, analysing the resulting products with commendable care, preparing curves of convincing character, and launching forth in a sea of theory and conjecture, apparently oblivious of the fact that in each experiment supposed to represent the changes at the particular temperature employed, they were dealing merely with a trace of those particular products diluted with every primary and secondary product formed at all temperatures below it. Some of these researches, like those of Mr. Lewis T. Wright, made as they were on working charges under working conditions in ordinary gasworks plant, are of the greatest possible value, as they represent what actually takes place in gas manufacture, with all its varying conditions, and are a contribution to our knowledge of an importance that cannot be over-estimated, but the class of research that deals with gram weights of material, carbonised under conditions that never have been and never can be attained in practice, are of little interest save from a scientific point of view.

It is clear that to obtain any insight into the actions taking place in the destructive distillation of coal, the quantity and composition of the tar is quite as important as the volume and composition of the gas, and a knowledge of the composition of the coke is also essential.

Long ago it was recognised by the gas-manager that the small coal-testing plants in which 2·24 lbs. of coal were distilled, gave results which did not agree with works' practice, the yield of coke on the small-scale experiment being too low and the tar too high, whilst the gas was generally higher in candle-power. This is due to the whole mass rapidly heating up and the tar vapours distilling out without there being any cooler portion of the charge for them to condense in, so that they yield the minimum of pitch and carbon to the coke, whilst the gas has but little surface contact to degrade it. Constam and Kolbe found that, using 1·1 lb. of coal, the yield of coke was 2·7 per cent. lower and the tar 1·6 per cent. higher than the results given by the same coal when used on a large scale.

When, however, one comes to the use of 2 grams of coal, as has been done by some recent investigators, the results obtained are ludicrously wrong—a Silkstone coal being credited with yielding 16·2 per cent. of tar at 750° C., or over thirty gallons, and 10·9 per cent. at 1050° C., whilst at 450° C. it yields only 4·29 per cent.; in actual practice we know that such a coal yields at 1000° C. about ten gallons, and at 450° C. about twenty-two gallons of tar.

The views I shall have to bring before you in

Hosted by Google

the next lecture are based upon the carbonisation of some thousands of tons of coal at low temperatures, and I think afford fairly clear evidence of the actions taking place.

SUDDITE.

Most travellers in the Sudan have observed the thick growth of sedge by which navigation is impeded in the White and Blue Niles above Khartum. For the last four years two Germans and an Englishman—Herr von Rath, Professor Hœring, and Captain Benett-Dampier—have been making experiments with the fibrous material that develops with such rapidity beneath the surface of the water, in the endeavour to manufacture a substance which may take the place of coal.

There is no natural coal in the Sudan, and the high price of imported fuel in the country makes industrial enterprise almost impracticable. The new fuel is called "Suddite," and it is made from the umsoof, grasses, papyrus, etc., which grow under water in the river. The supplies of sudd are immense, there being no less than thirty-five thousand square miles in existence.

If this invention can only be put into working operation, an extraordinary impetus will be given to the trade of the country, the effects of which can hardly be exaggerated. In April, 1911, Captain Benett-Dampier opened an experimental factory for suddite briquettes at Khartum. The Sirdar, Sir Reginald Wingate, and a large number of persons were present at the opening and, in the presence of the guests, a quantity of raw sudd was chopped, dried and pressed into small, compact briquettes suitable for commerce. The Sudan Government had taken a keen interest in the undertaking and had promised a monopoly should the experiments be absolutely successful, and providing it could be proved that a fuel from the soil of the Sudan had actually been found. The Government were anxious that the country should not be discredited by bad finance or unreliable schemes. To satisfy them the Khartum factory was erected. The tests were very exacting, and proved the virtues of "suddite" to be genuine, and Government has granted the concession.

To compare the relative merits of coal and sudd, a steamer was run up the White Nile for a prescribed journey of sixty-five miles on a certain day with the best Welsh coal. Next day the same journey was done with "suddite." With coal the journey was done in seven hours; with "suddite" in seven hours and seven minutes. The cost of coal to the Government at Tewfikieh, where fuel is most in demand for supplying the dredgers maintained in the sudd region for keeping the river channels clear, is 400 piastres, or £4 2*s.* 1*d.* per ton, whereas the suggested sale price of "suddite" to the Government is 22*s.* 6*d.* per ton. As it takes two tons of "suddite" to do the work of one ton of coal, it is at once seen that the reduction in the sum spent in fuel will be almost a half of that now expended. The sudd growth consists of plants of from fifteen to twenty feet high. So rapid is the development that within three weeks of cutting it has again grown to a height of seven and a half feet. After it has been cut it is tied into faggots, made into rafts, and simply floated down the river in the charge of a couple of natives, so that transport expenses are practically nil.

Big "suddite" works are planned for Tewfikieh, many miles down the river. The factory at Khartum is small, and was only built for the experimental tests required by Government. The difficulty at the moment seems to be the cost of transport of the briquettes from the big factory down the river.

The inventors of "suddite" believe that it has immense possibilities. If it can be brought into general use throughout the Sudan as a cheap fuel, there is no reason why that country should not be available for cotton-ginning, rice-milling, and the manufacture of sugar. It should also considerably help the work of irrigation, and so be the means of assisting agriculture.

In a recent interview, Captain Benett-Dampier alluded to a process being investigated for the enriching of "suddite." It seems probable that the process will be successful. If so, it will mean that one ton of "enriched suddite" will do the work of three tons of coal, and this at an extra cost of a few shillings a ton in the manufacture. "Suddite" could then be exported to Port Sudan and used for all the coaling on the Red Sea.

ELECTRIC LIGHTING OF RAILWAY TRAINS: THE BRAKE-VEHICLE METHOD.*

By ROGER T. SMITH, B.Sc., Assoc.M.Inst.C.E.

The method of train-lighting considered is that in partial use on the Great Western Railway, where axle-driven dynamos and batteries controlled by an automatic regulator are installed on brake-vehicles only. The lamps throughout the train are supplied from these equipments, which work in parallel with each other, the brake-vehicle equipments and the lamp-wiring in the coaches dependent on them being connected electrically by through wiring coupled between coaches. There is consequently an appreciable reduction in initial cost and upkeep of plant, and, what is of chief importance from the railway point of view, increased reliability. Mr. William Langdon's paper, read before the Institution of Civil Engineers in 1891, describes his, the first, attempt to light electrically passenger rolling-stock in general, in place of lighting set or block trains which were never broken up in traffic. Mr. Langdon's final method provided one axle-driven dynamo in the block part of a main-line train, and a battery on each of the other coaches. All coaches

* Abstract of a paper read by Roger T. Smith, B.Sc., Assoc.M.Inst.C.E., at the Institution of Civil Engineers.

Hosted by Google

were electrically coupled, and when uncoupled the lighting of each coach was continued during its branch journey by means of the charged battery. For any method of electric train-lighting applicable to all passenger rolling-stock the alternatives are either some such method as proposed by Mr. Langdon, or that every coach is "self-lit," that is to say, provided with it own axle-driven generator and battery. Other methods are either not applicable to passenger stock as a whole, or unsuitable for English railways.

The first aim of any method of train-lighting should be to light passenger rolling-stock adequately and with reliability. Measurement and experience lead to the provision of an illumination, measured on a horizontal plane at eye-level, of 2 foot-candles in 3rd class, and $2\frac{1}{2}$ foot-candles in 1st class compartments. Glare or dazzle can be minimised, if not entirely prevented, by keeping lamps out of the line of sight, by providing a white background behind the glowing filament, or by reducing the intrinsic brilliancy of the filament by enclosing the lamp in a diffusing globe or Holophane globe, the latter at the same time improving distribution. The tungsten train-lighting glow-lamp now replaces the carbon glow-lamp, its most economical efficiency with present train-lighting lamps being 1·3 watt per candle. On the average, tungsten glow-lamps, with a useful life of 850 hours, now have to be changed only once a year in the electrically-lit coaches on the Great Western Railway, where lamp-voltage is regulated within $\pm 2\frac{1}{2}$ per cent.

Any axle-driven system must in the first place provide a lead cell or other accumulator, so that the lamps are lit whether the train is standing or moving throughout its range of speed. In order to draw proper attention to the importance of the accumulator in train-lighting, it is both convenient and useful to look upon the accumulator as the essential element and on the dynamo as a device for making the output of the accumulator continuous throughout the hours of lighting. As typifying the accumulator the lead cell alone is considered. The two extremes among methods of charging lead cells are charging at constant voltage and charging at constant current, but a method of charging which combines the advantages of both extremes, while avoiding their disadvantages, is recommended, the charge being completely under the control of an automatic regulator set to give the proper compromise. The arrangement consists in starting with a heavy charge and gradually reducing it until, after proper gasing has taken place so as to mix the electrolyte, the charge is stopped when the cells are full, or the battery is left floating on the load while lights are on. Automatic regulation is necessary to secure a long and healthy life for the lead cell, and to reduce maintenance it is essential; when properly arranged, 10 per cent. per annum of the initial cost of the whole cell will provide for both maintenance and renewals of the plates and boxes.

The train-lighting dynamo is of secondary interest as compared with the battery, the essential element being some means of keeping the voltage constant at all speeds while permitting of its automatic variation by the regulator when required. The suspension and driving of the dynamo and the reduction of belt losses and renewals are among the chief factors in success. The automatic cut-in cut-out switch for connecting or disconnecting the dynamo from the battery should be actuated electrically, since the voltage of the latter may vary 25 per cent. from that of the former at any given speed. It is desirable that this switch should also act as an instantaneous automatic reverse-current circuit-breaker. The problem of automatic regulation has not attracted the British inventor as compared with other inventors on both sides of the Atlantic. The functions of an ideal regulator, combining in one or two instruments battery and lamp-voltage regulation, may be defined briefly as the following: First, it must control the lamp-voltage within $\pm 2\frac{1}{2}$ per cent. of the rated voltage of the lamps, and, within reasonable limits, must do so independently of lamp-load and entirely independently of battery-voltage. Secondly, when lamps are off, the regulator must control the generator-field so as to provide the full output of the dynamo for charging an empty battery; and when lamps are on, the balance of the full output must be available for charging. As charging proceeds the regulator must control the inherent regulation of the dynamo so that its voltage only rises sufficiently to give a diminishing charging current. Thirdly, with a fully-charged battery and lamps off, the regulator should reduce the charging current to zero. Fourthly, with a fully-charged battery and lamps on, the dynamo output must be adjusted to equal the lamp-load, leaving the battery in a floating condition with current neither entering nor leaving it. The foregoing requirements can to-day be obtained combined in one piece of apparatus.

To reduce the initial cost of electric train-lighting it is of first importance to reduce the number of battery cells, since within train-lighting limits it is the number of cells to be maintained, and not their size, which counts. The number of dynamos and regulators may be reduced in the same proportion. With the exception of through coaches transferred from main to branch lines, every train on the Great Western Railway has at least one brake-vehicle controlling it for traffic purposes, and all coaches which leave or join a main-line train *en route* are either brake-vehicles themselves, if detached or attached as single vehicles, or, if two or more coaches are detached or attached, they are controlled by a brake-vehicle. If every brake-vehicle is equipped with a generator and battery, the remaining coaches being wired only, while through wiring and couplers, designed to connect all vehicles together electrically, are provided on every coach, a less costly method of lighting trains is assured, as compared with the

Hosted by Google

equipment of every coach as a self-lit vehicle. In addition, much greater reliability is secured by working two or more dynamos and batteries in parallel. This arrangement of equipment it is proposed to call the "brake-vehicle" method, because under ideal circumstances only brake-vehicles need be equipped. On the assumption that all Great Western passenger rolling-stock might be equipped for electric train-lighting, the percentage of brake-vehicles would be 27, of dependent coaches 40, and of self-lit coaches 33 for main-line working, while for local and suburban traffic the percentage of brake-vehicles would be 39 and of dependent coaches 61. If the ratio of brake-vehicles to dependent coaches were as one to three, and there were no self-lit coaches, the initial cost of equipping an entire rolling-stock of some thousands of coaches would be reduced by about 35 per cent. as compared with self-lit equipments, and the working costs would be reduced about 40 per cent. The increased reliability due to a higher percentage of generator coaches is, however, of greater importance to the railway than reduction in cost. In addition to the electrical requirements already specified for the ideal equipment, others are specially needed for the brake-vehicle method. It is of primary importance that the dynamo should be capable of running with its brushes short-circuited, while in addition its output must be capable of being quickly altered by a simple adjustment to suit altered traffic conditions.

An experimental six-coach train lit on this method was run nearly continuously for two years in all sorts of traffic, varying from fast main-line services to slow, stopping, local services. Two brake-vehicles, equipped with 45-ampere dynamos, regulators, and 180-ampere batteries, light themselves and three dependents. A self-lit detachable coach completes the train. The Leitner system provided the only available apparatus able to meet the special conditions. All the equipments are in parallel, coupled through cables throughout the train providing for this. For the lighting circuits the through wiring and method of coupling is arranged on the loop-positive system, one regulator controlling the lamp-voltage on each side of the loop. The same looped-positive brake-vehicle method has been applied to two trains running on South Wales services, to two new trains specially built for the Cunard boat-service between Paddington and Fishguard, and to two new trains used for Birmingham local services; and it is being further applied. The bus-bar system of through wiring, a simplification of the looped-positive system, is now being adopted. By the bus-bar system greater simplicity and increased reliability are secured as compared with the looped system, but at greater cost.

The total annual cost of lighting a six-coach train on the looped-positive brake-vehicle method is as follows. The cost of the initial equipment would be £761, inclusive of all carriage-work charges; adding working costs, extra cost of locomotive-power—determined experimentally—and capital charges, the total annual cost becomes:—

	£
Working costs	45
Power to drive dynamos, 1½ per cent. on £875	13
Haulage of extra weight, 1·7 per cent. on £875	15
Interest on £761 at 4 per cent.	30
Reproduction of capital in 20 years at 3 per cent.	23
Total annual cost of lighting a six-coach train	£126

With regard to the safety of electric train-lighting, although at 22 volts an arc can be formed between any of the metals employed in train-lighting, this arc will not persist. Provided the ordinary precautions necessary with electric circuits are taken, and suitable fuses are used and properly maintained, it is believed that complete immunity from fire risks can be ensured.

HOME INDUSTRIES.

Employers and the Insurance Act.—The Employers' Parliamentary Association is the outcome of a meeting of employers held in Manchester, at which it was unanimously resolved to form the Association. In the opinion of the founders of the Association, the trend of legislation makes it imperative that employers of labour shall be able collectively to take action with regard to any legislation which directly affects industry and commerce, business men having a right to be consulted on all such legislation. The immediate work of the Association will be to carry on the opposition to the National Insurance Act, and by all legitimate means to delay the application of the measure until its provisions are made acceptable to employers and workpeople. There is no intention to interfere with any of the existing Parliamentary associations; rather, it is hoped that all will co-operate, so that united action may be taken by every branch of trade and industry in the United Kingdom. All the great industries are interdependent, and united action is therefore essential. The Association will take measures to enlighten workpeople as to the effect of the Act, and will, wherever possible, ascertain their views by ballot. It will consider the regulations to be issued by the Commissioners; oppose or obtain modifications of regulations which are considered inequitable, and those likely to produce friction between employers and workpeople, and suggest amendments to the regulations by deputation to the Commissioners or otherwise. It will set up machinery by which the opinion of employers of labour will be obtained on any present or prospective legislation affecting industry and commerce. It is believed that the Association will be of much service, particularly to the many thousands of employers who do not belong to any Parliamentary organisation, since it

Hosted by Google

will provide the opportunity for combination. The committee strongly urges on small traders the importance of becoming members of the Association, as they will in many cases be severely affected. The chairman of the provisional committee is Sir C. Macara, and the secretary (*pro tem.*) Mr. George Moores, who will be happy to give further particulars to any one who may write to him at 14, Cross Street, Manchester.

The Export and Home Trade in Cotton Goods.—As bearing upon the effect of the Insurance Act on the Lancashire cotton trade, it has been pointed out that a greater proportion of the British cotton trade is an export trade than in the case of any of its foreign competitors, and a correspondent of the *Manchester Guardian* has made a comparison of the position of the United Kingdom, France and Germany in this report. "If," he writes, "we represent the estimated number of spinning spindles (as given in the International Federation report) and the value of the exports of yarn and manufactures of the United Kingdom as 100, and calculate the similar figures for France and Germany as a proportion of this, we get the following comparison :—

	Spindles (in thous'ds).	Percentage of U.K.	Exports (1909) in £1,000.	P'centage of U.K.
U. Kingdom	54,522	100	93,444	100
Germany	10,480	19	18,222	19
France	7,300	13	13,658	14

Germany has 19 per cent. of the number of British spindles, and exports 19 per cent. of the value exported by Great Britain. France has 13 per cent. of the number of British spindles, and her exports amount to 14 per cent. of the British exports. This remarkable similarity of the proportions shows that in both Germany and France the proportion of exports to the total trade is roughly the same as in the case of Great Britain, unless the assumption can be maintained that the value of the output per spindle in Germany and France is much greater than in the United Kingdom. The consumption of raw cotton per spindle is definitely known to be much greater in the two foreign countries, but this does not affect the comparison. An additional inference of great importance may be drawn from these figures. The proportion of the British home trade to the total trade is usually placed at 20 per cent. If the same proportion applies in the case of the other two countries, it follows that Germany is clothing a population of 65 millions with one-fifth of the product of 10,480,000 spindles, France is clothing a population of 38 millions with one-fifth of the product of 7,300,000 spindles, while the United Kingdom is clothing a population of 45 millions with one-fifth of the product of 54,500,000. This throws an illuminating sidelight on the comparative purchasing powers of the three nations, nor is any difference in the yardage output per spindle or in the value of imports or in the use of wool, linen, etc., likely to make much difference to the comparison." These inferences must, however, be accepted with some reserve, since, as the *Manchester Guardian* points out, the piece goods exported by the United Kingdom are, in the main, of a much cheaper kind than those retained for home consumption, and also, it may be assumed, of a cheaper kind than those exported by France and Germany, which are more akin to their home trade goods. The difference in relative values would vitiate the calculation as to the proportion of the spindles employed for home trade and for export in the several countries.

Shipbuilding on the Thames.—The Government have intimated that they are prepared, upon certain conditions, to give a contract for the building of two protected cruisers, together with the engines, on the Thames forthwith, and to promise for next year the placing of two destroyers. The work is, of course, to be done at the Thames Ironworks, and the contracts are a concession to the East-end demand for a share of the shipbuilding work that has to be placed by the Admiralty. But it is by no means certain that the conditions insisted upon by the Admiralty will be accepted. These conditions are—that the work should be given to a northern company, and the company will not undertake the contract unless the men agree to work the same hours as are worked by men in the north; that is to say, fifty-three hours instead of the forty-eight that has ruled on the Thames for some time past. It is by no means certain that the men will agree to this return to a nine-hours' day. Moreover, exception is taken to the action of the Government in giving the contract to a northern company, understood to be the Palmer Shipbuilding Company, of Jarrow, without any consultation with the parties most directly concerned, namely, the Receiver of the Thames Ironworks and the interests he represents. Without expressing any opinion upon these knotty points, it may be hoped that the outcome of the negotiations will be the re-establishment of the Thames Ironworks and orders for the construction of men-of-war. It is of very great moment to the immense industrial district surrounding the works that they should be fully employed, and it is not less desirable, from the national point of view, that there should be works in the Thames where, in the event of a naval war, "lame ducks" may be taken for repairs.

The Telephone Transfer.—On Sunday last, at midnight, the Telephone Company ceased to exist, and 600,000 telephones passed under the dominion of the Post Office. The agreement, settled and signed in February, 1905, involves the transfer of £16,000,000 of capital and 18,000 employees. 1,253,890 miles of telephone wire are taken over by the State, and the capital value of the system has been estimated at £25,000,000. It may be remembered that the original licence of the National Telephone Company was for thirty-one years from

Hosted by Google

January, 1880, but the Company was granted no monopoly. The 10 per cent. royalty last year produced £350,000. Opinions differ considerably as to whether the transfer will give the public a better service. Many fear the contrary. There is a general impression that England is much behind other European countries in the use of the telephone—but that is a mistake. The only European country which can be compared with the United Kingdom in telephone development is Germany, but, of course, the development of telephony in the United States of America is much greater than anywhere else, and England has done less for the country districts than some other countries.

"*Back to the Land.*"—Mr. B. Seebohm Rowntree and Mr. Bruno Lasker have just published a very valuable treatise on unemployment (Macmillan, 5*s*. net). It is a work that should be closely studied by social students and politicians of all persuasions, but the object in referring to it here is to direct attention more particularly to Chapter 8, "A Valuable Suggestion from Belgium." Briefly, the suggestion is that the town worker should live in the country and cultivate a plot of land. This would give the worker a second string to his bow, of incalculable value when work fell off in the towns, and his children, being brought up in the village, would often settle there. The writers believe that a scheme enabling men to reside in the country, while working in the towns, would operate with steady and accumulative effect in lessening unemployment and the dire evils which now attend it, and that it would not retard, but tend to further extensive economic changes making for greater stability of employment. The system works excellently in Belgium, where, although only 23 per cent. of workers are engaged in agriculture, 56½ per cent. of the population are living in the country. It has been rendered possible in Belgium by the interaction of three essential economic conditions—(1) the possibility of obtaining without difficulty land in small plots, and in the desired localities; (2) the provision of cheap and rapid transit between town and country; (3) the provision upon easy terms of capital for the erection of houses. The plots vary in size from a small vegetable garden to one or two acres, or even more. The produce from the plot is not, as a rule, sold, but kept for home consumption. As Mr. Rowntree puts it, a family with a substantial garden—a quarter of an acre, for instance—may have to live hardly when no wages are coming in, but if there is a supply of potatoes and green vegetables, with possibly bran, and milk from a goat, they do not starve. These things just furnish the little reserve of wealth which tides over the difficulties. Plasterers, bricklayers, and other similar workmen, often do not trouble to look for work in towns when it is scarce. Even some of the Antwerp dockers, if they learn on arrival at the docks that very few ships are coming in, return home instead of swelling the army, already far too large, of men scrambling for the few vacancies that occur. Is a similar system practicable in England? It must be remembered that there is no country in Europe where land is so much subdivided as in Belgium, or where transit facilities are so good. Every tenth inhabitant, and every fifth adult, is a landowner, and the accumulation of land in a few hands is rendered impossible by the laws of succession. Then a ticket, enabling a workman to travel three miles to and fro for six consecutive days, costs 9*d*., or ¼*d*. a mile. If the distance to be travelled daily each way is 6¼ miles, the ticket costs 1*s*., or ⅛*d*. per mile. For 12½ miles each way it costs 1*s*. 2½*d*. a week, or $\frac{1}{10}$*d*. per mile. For 25 miles each way it costs 1*s*. 7*d*., or $\frac{1}{15}$*d*. per mile. The difficulties in the way of such cheap transit in England are obvious, but not necessarily insuperable, and there is plenty of suitable land that could be got, at from £70 to £80 downwards, whilst the necessary capital for laying out and developing the land and putting up buildings might be obtained by county councils exercising the powers given by the Small Holdings and Allotments Act, 1908, the money being borrowed from the Central Government at 3½ per cent. It is much to be wished that some one county council would make the experiment. Its results might well be more beneficial than those accruing from some of the more ambitious schemes which find favour in high quarters.

CORRESPONDENCE.

THE FISHERIES OF BENGAL.

In seconding a vote of thanks to Dr. Travis Jenkins for his paper on "The Fisheries of Bengal," my father, Sir George Birdwood, expressed the wish that I, when invited by the Chairman to speak, had done so. My reason for asking to be excused was a business one. It is to the commercial and financial side of the question that I have confined my attention. In the course of certain interpolations of an altogether delightful character, Dr. Jenkins introduced matter which seemed to modify preconceived opinions, and it was essential carefully to consider how his remarks affected the financial interests concerned.

When the question of forming an English company to develop the Indian sea fisheries was first mooted, the matter which principally appealed to those interested was the question of food supply for the inhabitants of India. The first inquiries, therefore, which had to be made were: are there edible fish in the Bay of Bengal, can those fish be caught, and can the catch be marketed? The evidence, which consisted of Dr. Alcock's report and certain practical details furnished by Captain Row from actual experience, clearly indicated that the supply of good fish is unlimited, that the fish harvest is perennial, that fish is a necessity to a rice-eating population, and that the demand for fish throughout India is practically unlimited, caste

Hosted by Google

prejudice affecting the question only to a small extent. Accordingly, the two main factors of success in any commercial undertaking, unlimited supply and unlimited demand, appeared to be present to a peculiar degree in the project.

The next question was the attitude of Government. It had always been understood that the Government of India were particularly desirous that these deep sea fisheries, and especially those of the Bay of Bengal, should be developed. Lord George Hamilton, when Secretary of State for India, had dealt with the salt tax on cured fish, and more recently Government had given practical proof of their desires by the appointment of Sir Krishna Gupta to inquire and report, and by the chartering of the "Golden Crown." I have had access to the correspondence passing between certain gentlemen in England and the Government of Bengal, and also the report of interviews in Calcutta with the Government representatives and the representatives of the English group. The outcome was that Government stated they were prepared to give the following assistance:—

(1) The grant of a rebate of the salt duty.
(2) The grant of lands for depots on the coast line wherever Government land was available.
(3) Their influence to induce the Port Commissioner to allot suitable quays at Calcutta or elsewhere.

In addition to the above, Government had been asked to aid the proposed enterprise, either by guaranteeing a dividend on the capital employed, or by guaranteeing a monopoly of the rebate of the salt duty for a period of years. In their memorandum to Government, the organisers of the enterprise had pointed out that a considerable amount of money would be risked in proving the industry on a commercial basis, and they went on to say:—"If our efforts are successful, we shall be prejudiced to the extent of this sum of money in favour of any competitors who may, utilising the knowledge which we have acquired, then enter the field against us; and we feel that we may fairly ask some privilege in return for this tentative initial outlay of capital." The request was refused; the matter is still deadlocked, and, in my humble opinion, for the following reason. India does not afford scope for individual private enterprise. If a pioneer of the type of Cecil Rhodes, having genius, courage, and cash, were looking round to-day for new openings, he would, I fear, turn his eyes away from India. India, so far as new local industries are concerned, has still to lean on local capital, and, so far as the Bengal fisheries are concerned, local capital does not appear to be very red hot. As a fact, a good many years ago, before the methods of steam trawling had reached the almost scientific perfection of to-day, certain individuals in India invested a little capital in a steam trawler with the idea of proving the fishing grounds; the money was lost, and the loss, perhaps, still galls. Now, in the absence of local capital in India, or private capital at home, the appeal has to be made to the public. That is done either by direct advertisement, which means several thousands of pounds at speculative risk, or by underwriting. Underwriters do not take "firm," they only guarantee that they will subscribe if the public does not. In the case of the Indian fisheries, underwriting cannot be done, because the underwriter, though he recognises the vast potentialities of the scheme, is of opinion that the public will not invest unless the dream has some substantial basis of Government support. If it were a tea garden, or a jute or cotton mill, or a gold mine, underwriting could, doubtless, be done, for the British public in those particular matters is more or less educated in Indian commercial affairs. But when a company proposes to work an Indian product for Indian consumption; when the earnings and profits are hypothetical, and are only based on what has been done under totally different circumstances in other parts of the world, I, for one, would not care to guarantee the chance of the British public coming in, unless the scheme were strengthened by some measure of Government support.

I do not suggest, or believe, that the present condition of affairs will endure. During Lord Curzon's Viceroyalty a most wholesome impetus was given to the introduction of British capital into India. For various reasons, local and otherwise, that stream of capital was headed off. Recent events may once more cause it to flow Indiawards; and, in that event, I feel confident that the underwriting difficulties will disappear, for, as I have said, these arise out of ignorant public apathy. With regard to the scheme generally I will not go into the question of estimates. Dr. Jenkins, so far as modern methods are concerned, confined his observations to the estuarine fisheries of the Bay of Bengal, claiming that without modern appliances, and simply by methodical management under European control, the existing native catch would be sufficient for Calcutta purposes. Dr. Jenkins, in fact, advocated the use of improved methods for the supply of fresh fish for Calcutta alone. But my view is not confined to Calcutta and its environments, or even to Bengal. As an initial business proposition, doubtless the supply of fresh fish for Calcutta organised in the manner suggested by Dr. Jenkins affords the best inducement for immediate investment, but such an organisation would not interest, for it would not require English financial support. But in my opinion it is the catering for the multitudes that is the key to the position; and that can only be done by cured fish. It is by means of cured fish that nutritious food could be brought within reach of the very poorest throughout the Peninsula; and I feel very confident that it is only by adequately developing the deep sea fisheries of the Bay of Bengal by means of modern sea trawlers that fish can be caught in sufficient quantities to supply the inland districts of India. Founding my judgment on the opinion of those who are well acquainted both with the local conditions and with all the ramifications of the trawling trade, I long ago came to the

Hosted by Google

conclusion that the scheme to develop this industry in Indian waters is one which has good prospects of great success. The finding of the fish, the catching of the fish, the delivery of the fish fresh in Calcutta, and the sale of the fish at a commercial profit, all appear to be capable of achievement, given sufficient capital and efficient management.

FRANK BIRDWOOD.

OBITUARY.

ISAAC JULIUS WEINBERG.—Mr. Isaac Julius Weinberg died at Brighton on the 1st inst., in his eightieth year. A German by birth, he was a member of the well-known jute firm of Messrs. Moore and Weinberg, of Belfast and Dundee. He was a man of great energy and ability, and did business in practically every part of the world. He played a prominent part in the negotiations which led to the French Commercial Treaty. He took a deep interest in education, and was a governor of University College, Dundee. He was a member of the Royal Society of Arts for just over half a century, having been elected in 1861.

NOTES ON BOOKS.

WHERE GREAT MEN LIVED IN LONDON. London: A. & C. Black. 1*s*. 6*d*. net.

The idea of this little book is good. It certainly gives pleasure and interest to many people to know the houses in which famous men have lived. As is well known, the work of marking such houses with memorial tablets was initiated by the Royal Society of Arts, and is now carried on with admirable care by the London County Council. The work is progressing but slowly; but any one who reads the pamphlets published from time to time by the Council will realise how extremely difficult it is in many cases to identify an old house beyond a doubt. Streets may be renumbered, houses may be pulled down; two may be made into one, or one into two—in short, in neighbourhoods of any antiquity where the builders have been active, the most minute and painstaking research is often necessary before one can state, with confidence, that this is the house in which So-and-so lived. In illustration of this, Lord Rosebery, in unveiling the tablet to the memory of Lord Macaulay at Campden Hill—the first, by the way, ever set up by the County Council—told an amusing story. "I myself," he said, "have been in the habit of sometimes trying to find the houses of distinguished men without the guidance of a memorial tablet. I used to be greatly gratified by the reflection that the second Pitt had lived in Berkeley Square at the time of the formation of his first Government, and, having got the number, I was accustomed to show my friends who were walking with me, when conversation flagged, the house of the younger Pitt. It was something of a blow to me to be assured by the historian of Berkeley Square, who had given great attention to the matter, that the numbers had all been changed, and to find that I had been lavishing an immense degree of unnecessary sympathy, and had been creating a vast amount of spurious sentiment, on a house which had no more to do with Mr. Pitt than it had to do with Lord Macaulay."

The cynic may assert that, when gazing at the wrong house, Lord Rosebery enjoyed just as fine a thrill as when he afterwards found the right one; but most persons will agree that of this particular branch of study, exactness is the very essence. And this is the quality in which the little volume under notice appears to be somewhat deficient. For instance, if one looks under the heading "Stoke Newington," one finds eleven entries, but of these only four are given any more particular address; and it would certainly require a more than ordinary power of appreciating associations to enable a man to gaze with interest at that lugubrious district, because it was the home of Dr. Aikin, Mrs. Barbauld, and various other ladies and gentlemen.

AN ANALYSIS OF THE CHURCH OF ST. MARY, CHOLSEY, IN THE COUNTY OF BERKSHIRE. By F. J. Cole, D.Sc. (Oxon.), Professor of Zoology, University College, Reading. Oxford: B. H. Blackwell. 5*s*. net.

An interesting scheme has been initiated by the authorities of University College, Reading. The town and its neighbourhood abound in subjects for historical research, and in order "to stimulate public interest in the history of the locality, and to afford a means by which the general historical teaching at University College may gradually become connected with, and be illustrated by, the detailed evidence which is furnished by local history," a fund has been started to defray the cost of the publication of studies dealing with particular aspects of this history. This is the third volume of the series, the first being "The Town of Reading during the early part of the Nineteenth Century," by W. M. Childs, M.A., Principal of University College, Reading (who is general editor of the series), and the second "The Place Names of Berkshire," by F. M. Stenton, M.A., Research Fellow in Local History, University College, Reading.

The Church of St. Mary, Cholsey, has a twofold interest—its ancient foundation and its intrinsic beauties. If there is no actual Saxon building still extant, the church certainly stands on the site of a Saxon monastery, and the ground plan indicates that it was once a very considerable ecclesiastical centre. Professor Cole gives a minute and careful description of the building, illustrating it with drawings of mouldings, plans, and some excellent photographs. The volume is a model of what such a monograph should be.

THE ELEMENTS OF PERSPECTIVE. By Aaron Penley. Revised and partly rewritten by A. P. Killik and D. B. Hedderwick. London: Winsor and Newton. 1*s*. net.

It is scarcely necessary to call attention to the merits of this well-known little handbook. It has now reached its forty-seventh thousand, and is in general use in schools and colleges where art is studied at all seriously. The present edition has been, to a large extent, rewritten, and both the text and illustrations have been considerably simplified. It is now very succinct and clear, and in little over sixty pages it takes the student from the drawing of a simple cube to the perspective of a cruciform church.

GENERAL NOTES.

NIGHT SIGNALS FOR AVIATION.—The use of illuminated captive balloons for the purpose of guiding aeronauts and aviators on their way by night is being tried in Germany. One of these has lately been placed at Treplow (between Berlin and Stettin). The balloon, which is 2½ metres (about 8 feet) in diameter, is of a red colour, and carries an electric light. It is visible for a great distance at night, and is easily distinguished from any other light. In case of fog, when the light could not be seen, an electric bell is caused to ring by means of a hygrometer attached. In this way it is possible for a person in charge to ascertain the height of the fog zone, and cause the balloon to ascend into a less moist and clearer atmosphere, when the bell will cease ringing.

MEMORIAL TABLETS.—A memorial tablet has been affixed to No. 22, Hereford Square, Brompton, the house in which George Borrow lived from 1860 to 1874. He had before this time reached the height of his fame, and during the period of his residence in London his literary output was not considerable. A tablet has also been affixed to No. 13, Johnson Street, Somers Town, where Charles Dickens spent a part of his boyhood. Two other houses, No. 48, Doughty Street and No. 1, Devonshire Terrace, had previously been indicated by the London County Council as the novelist's residences at later periods of his career. A further tablet has recently been affixed to No. 17, Red Lion Square, W.C., which was for a short time the home of that remarkable triumvirate, Dante Gabrielle Rosetti, William Morris, and Edward Burne-Jones.

THE PRODUCTION OF FIBRE FROM NETTLES IN AUSTRIA.—The spinning department of the Kaiser Franz Josef School of Textile Industry, in Reichenberg, is now experimenting with the cleaned fibre of the nettle. By the new Austrian process, the gum is extracted from the fibre of the plant by mechanical, and partly by chemical means. The stalks are relieved of their wood, resin, and rubber substances by pressure. The experiment station at Brunn has succeeded in completely separating and spinning the fibres furnished without destroying their tension or firmness. These experiments were made on knitting yarn machines, and yarns were produced which it is claimed, owing to their excellent qualities, can be used in various branches of weaving and knitting, in the production of furniture covers, blankets, tapestries, damasks, cloths, ribbons, laces and underwear. The inventors of the new process believe that, sooner or later, nettle fibre will largely replace cotton, and that by the same process spinning fibre can be obtained from the stalks of hops and other plants.

THE OUTPUT OF BRITISH COAL IN 1910.—The annual report by the Chief Inspector of Mines on the output of mines and quarries for 1910 (Cd. 5977) contains, as usual, some interesting statistics. The total value of the minerals raised in the United Kingdom during the year was £122,105,582, an increase of £2,728,643 over the total for 1909. This difference is mainly accounted for by the rise in the value of coal. The total output of coal was 264,433,028 tons, and the value £108,377,567—increases of 658,716 tons and of £2,102,667 respectively on the figures for 1909. The average price of coal was 8*s*. 2·36*d*. per ton in 1910 as compared with 8*s*. 0·7*d*. in 1909. Continental countries purchased less British coal in 1910 than in the previous year, and the quantity of coal exported (exclusive of coke, manufactured fuel, and coal shipped for the use of steamers engaged in foreign trade) was almost a million tons less than that for 1909, viz., 62,085,746 tons. The decrease would have been greater but for the fact that more coal was exported to South America than in the previous year. France received over 9½ million tons, Germany over 9 million tons, Italy over 8¾ million tons, Sweden nearly 4 million tons, Russia nearly 3¼ million tons, Egypt, Spain, the Argentine and Denmark each over 2½ million tons, and the Netherlands nearly 2½ million tons. Adding the 2,930,467 tons exported in the form of coke and manufactured fuel, and the 19,525,735 tons shipped for the use of British and foreign steamers engaged in foreign trade, we find the total quantity of coal which left the country in 1910 was 84,541,678 tons, as against 86,037,006 tons in 1909.

SIAMESE ELEPHANTS AND IVORY.—Roughly estimated, the number of domesticated elephants in Siam is about three thousand. The supply has been decreasing yearly and prices have advanced, until now a full-grown male elephant is worth about £500 and a female £350, according to the American Vice-Consul at Bangkok. Travel in northern Siam, especially during the rainy season, would be impossible without the elephant, and he is used to great advantage in the teak wood industry. An elephant is full grown at twenty-five years, but not in full vigour until thirty-five. The length of life is eighty to one hundred and fifty years, and the average weight is about three tons. In Siam the elephant carries only two hundred and fifty to five hundred and fifty pounds according to the size of the

Hosted by Google

animal. No estimate can be made of the number of wild elephants in the jungles of Siam, but in one of the elephant drives in the Ayuthia district recently, more than two hundred were seen at one time. Permission to capture wild elephants may be obtained from the Siamese Government, and for each animal caught a royalty of £30 is paid, but such capture is exceedingly difficult and expensive. The export of ivory in the fiscal year ended March 31, 1910, amounted to 4,301 pounds, and that is a fair average of the export for the past five years.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings, at 8 o'clock:—

January 17.—Cyril Davenport, F.S.A., "Illuminated MSS." Sir Walter Armstrong will preside.

January 24.—William J. Gee, "Hydraulic Separating and Grading."

January 31.—Professor G. W. Osborn Howe, "Recent Progress in Radio-Telegraphy." Sir William H. White, K.C.B., F.R.S., will preside.

February 7.—Leonard Hill, M.B., F.R.S., and Martin Flack, M.A., M.B., B.Ch., "The Influence of Ozone in Ventilation."

February 14.—Cecil Thomas, "Gem Engraving." Sir Arthur John Evans, D.Litt., LL.D., F.R.S., will preside.

Indian Section.

Thursday afternoons, at 4.30 o'clock:—

January 18.—The Rev. Walter K. Firminger, B.D., Senior Chaplain, Bengal Establishment, "The Old District Records of Bengal." Sir James A. Bourdillon, K.C.S.I., will preside.

February 8.—Colonel Sir Thomas H. Holdich, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc., "The North-East Frontier of India."

March 14.—E. A. Gait, I.C.S., C.I.E., Census Commissioner for India, "The Indian Census of 1911."

April 25.—Walter Saise, D.Sc., M.Inst.C.E., Hon. Member Institute of Mining and Geology, India, A.R.S.M., V.D., "The Coal Industry and Colliery Population of Bengal."

May 16.—Neville Priestley, Managing Director, South Indian Railway, "Indian Railways."

Colonial Section.

Tuesday afternoons, at 4.30 o'clock:—

January 30.—W. A. Legg, M.Inst.C.E., late Supervising Engineer, Irrigation Department, Cape Colony, "Irrigation in South Africa." The Hon. Sir Richard Solomon, G.C.M.G., K.C.B., K.C.V.O., K.C., High Commissioner for the Union of South Africa, will preside.

March 26.—R. H. Barraut, Resident at Jesselton, "British North Borneo."

May 7.—Alan Burgoyne, M.P., "Colonial Vine Culture."

Cantor Lectures.

Monday evenings, at 8 o'clock:—

Vaughan Cornish, D.Sc., F.G.S., F.C.S., "Ocean Waves, Sea-Beaches, and Sandbanks." Two Lectures.

Syllabus.

Lecture I.—January 22.—The size and speed of ocean waves—The height of waves in lakes, seas, and rivers—The length of waves in lakes, seas, and rivers—The steepness of waves, and strains upon ships—The periodic time of waves, and the rolling of ships—The speed of waves and its relation to velocity of wind—The height of waves and its relation to velocity of wind—The time required to develop large waves, and the duration of storms—The length and speed of the swell observed after storms—The probable height of the swell during storms—The relation between the dimensions and path of a cyclonic depression and the nature of the winds produced—The depth in which waves break, and its relation to defence works.

Lecture II.—January 29.—The action of waves and tidal currents on sea-beaches and sandbanks—The proper action of waves to drive sand and shingle shoreward—The proper action of waves to drive mud seaward—Special conditions under which the action on sand is reversed—The proper action of the tide to drive shingle in the direction of the flood—The normal removal of shingle from promontories and its accumulation in bays—The exceptional accumulation of shingle in salient positions, *e.g.*, at Dungeness—Groynes—The reason of the graded arrangement of shingle on the Chesil beach—The formation of a sandbank on the up-channel side of a promontory—Sandbanks in estuaries and their arrangement by tidal currents—Their rippled surface as a means of mapping these currents—Their influence on the formation of tidal bores—The struggle between land water and tidal water to arrange the sandbanks in the Severn—The variability of the Severn Bore as determined by these factors—The circumstances which determine the starting point of the Severn Bore.

Loudon M. Douglas, F.R.S.E., "The Meat Industry." Three Lectures.

February 5, 12, 19.

Luther Hooper, "The Loom and Spindle: Past, Present, and Future." Three Lectures.

February 26, March 4, 11.

Noel Heaton, B.Sc., F.C.S., "Materials and Methods of Decorative Painting." Three Lectures.

March 18, 25, April 1.

Hosted by Google

HOWARD LECTURES.

Monday evenings, at 8 o'clock:—

CAPTAIN H. R. SANKEY, R.E., M.Inst.C.E., "Heavy Oil Engines." Four Lectures.

April 29, May 6, 13, 20.

Dates to be hereafter announced:—

H. A. ROBERTS, M.A., "The Relations of Science to Commerce and Industry." PRINCIPAL SIR HENRY A. MIERS, M.A., D.Sc., F.R.S., will preside.

F. MARTIN DUNCAN, "The Work of the Marine Biological Association."

JOHN NISBET, D.Oec., late Conservator of Forests, Burma, "The World's Decreasing Timber Supplies."

FRANK WARNER, "Silk."

CHARLES C. ALLOM, "The Development of Artistic Skill in the Applied Arts."

ERNEST KILBURN SCOTT, Assoc.M.Inst.C.E., M.I.E.E., "The Manufacture of Nitrates from the Atmosphere."

CHARLES BRIGHT, F.R.S.E., M.Inst.C.E., M.I.E.E., "The Administration of Imperial Telegraphs."

HAROLD COX, "The Interdependence of Morals and Economics."

E. D. MOREL, "British Rule in Nigeria."

GORDON CRAIG, "Art of the Theatre." MISS ELLEN TERRY will preside.

THEODORE E. SALVESEN, "The Whaling Industry of To-day."

PROFESSOR ERNEST A. GARDNER, M.A., "Greek Sculpture."

GEORGE FLETCHER, "Technical Education in Ireland."

MEETINGS FOR THE ENSUING WEEK.

MONDAY, JANUARY 8...Post Office Electrical Engineers, at the Institution of Electrical Engineers, Victoria-embankment, W.C., 5 p.m. Mr. A. J. Stubbs, "Precautions against Fire."

Chemical Industry (London Section), Burlington House, W., 8 p.m. 1. Messrs. C. T. Kingzett and R. C. Woodcock, "The Production of Formic and Acetic Acids by the Atmospheric Oxidation of Turpentine." 2. Messrs. C. Davis and J. L. Foucar, "A Rapid Volumetric Method for the Determination of Free Sulphur." 3. Messrs. W. P. Dreaper and W. A. Davis, "The Relative Adsorption of Dyes by Sand and Natural Fibres." 4. Mr. W. P. Dreaper, "Ingrain Dyeing—Influence of Certain Groups on the Re-solution Factor."

Surveyors, 12, Great George-street, S.W., 8 p.m. Mr. Frank W. Hunt, "The Tendency of Recent Modifications of the Lands Clauses Act."

Geographical, Burlington-gardens, W., 3 p.m. (Juvenile Lecture.) Mr. W. H. Garrison, "Our World-Wide Empire."

Victoria Institute, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Rev. Professor G. Milligan, "The Greek Papyri."

London Institution, Finsbury-circus, E.C., 5 p.m. Mr. W. L. Courtney, "Learned Greek Women: Sappho and Aspasia."

TUESDAY, JANUARY 9...Cold Storage and Ice Association, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m.

Asiatic, 22, Albemarle-street, W., 4 p.m. Mr. D. G. Hogarth, "Carchemish."

Royal Institution, Albemarle-street, W., 3 p.m. (Juvenile Lecture.) Dr. P. Chalmers Mitchell, "The Childhood of Animals." (Lecture VI.)

Civil Engineers, 25, Great George-street, S.W., 8 p.m. 1. Mr. S. H. Ellis, "Reinforced-Concrete Wharves and Warehouses at Lower Pootung, Shanghai." 2. Mr. W. C. Popplewell, "The Direct Experimental Determination of the Stresses in the Steel and in the Concrete of Reinforced-Concrete Columns." 3. Mr. W. H. Burr, "Composite Columns of Concrete and Steel."

Automobile Engineers, at the Institution of Mechanical Engineers, Storey's-gate, S.W., 8 p.m. Mr. D. J. Smith, "The Repair of Motor Vehicles."

Colonial, Whitehall Rooms, Whitehall-place, S.W., 8.30 p.m. The Earl of Dudley, "Some Impressions of Australia."

WEDNESDAY, JANUARY 10...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5 p.m. (Juvenile Lecture.) Mr. C. Vernon Boys, "Soap Bubbles." (Lecture II.)

Geological, Burlington House, W., 8 p.m. Mr. S. Hazzledine Warren, "On a Late Glacial Stage in the Valley of the River Lea, subsequent to the Epoch of River-Drift Man."

THURSDAY, JANUARY 11...Cyclists' Touring Club, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8.30 p.m. Mr. E. C. Russell, "A Modern Canterbury Pilgrimage."

Concrete Institute, 296, Vauxhall Bridge-road, S.W., 8 p.m. Discussion on the Reports on "The Standardisation of Drawings for Reinforced-Concrete Work," and on the "Consistency of Concrete."

London Institution, Finsbury-circus, E.C., 6 p.m. Mr. C. E. Lowe, "Beethoven—the Man and his Music."

Automobile Engineers (Graduates' Section), 13, Queen Anne's-gate, S.W., 8 p.m. Mr. A. R. Pettit, "Balancing."

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Mr. W. Thomas, "Tramps with a Camera."

Electrical Engineers, Victoria-embankment, W.C., 8 p.m. Mr. C. A. Ablett, "Some General Principles involved in the Electric Driving of Rolling Mills."

Mathematical, 22, Albemarle-street, W., 5.30 p.m.

FRIDAY, JANUARY 12...Malacological Society, Burlington House, W., 8 p.m. 1. Mr. W. H. Dall, "Note on the Genus *Panope* Ménard." 2. Mr. A. J. Jukes-Browne, "Nomenclature of the *Veneridæ*; A Reply to Dr. W. H. Dall." 3. Mr. A. W. Stelfox, "The Occurrence of *Helicella heripensis* in Great Britain; Notes on Some British Non-Marine Mollusca." 4. Mr. G. K. Gude, "Characters of Two Undescribed Land Shells from Colombia; Explanation of the figures occurring in Westerlund's 'Sibirien's Land och Sottvatten Mollusker,' 1876; on two preoccupied specific names in *Gasteropoda*."

Astronomical, Burlington House, 5 p.m.

Medical Officers of Health, 1, Upper Montague-street, W.C., 5 p.m. Dr. William Butler, "The Exclusion of Infected Children from Schools."

British Foundrymen's Association (London Branch), Cannon-street Hotel, E.C., 8 p.m. Mr. H. C. W. Carpenter, "Growth of Cast-Iron."

SATURDAY, JANUARY 13...North-East Coast Institute of Engineers and Shipbuilders, Bolbec Hall, Newcastle-on-Tyne, 7.30 p.m. Mr. H. C. Stroud, "Wireless Telegraphy for Naval Purposes."

Hosted by Google

Journal of the Royal Society of Arts.

No. 3,086. VOL. LX.

FRIDAY, JANUARY 12, 1912.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

WEDNESDAY, JANUARY 17th, 8 p.m. (Ordinary Meeting.) CYRIL DAVENPORT, F.S.A., "Illuminated MSS." SIR WALTER ARMSTRONG will preside.

THURSDAY, JANUARY 18th, 4.30 p.m. (Indian Section.) The REV. WALTER K. FIRMINGER, B.D., Senior Chaplain, Bengal Establishment, "The Old District Records of Bengal." SIR JAMES A. BOURDILLON, K.C.S.I., will preside.

JUVENILE LECTURES.

On Wednesday afternoon, January 10th, Mr. CHARLES VERNON BOYS, F.R.S., delivered the second and final lecture of his course on "Soap Bubbles."

Frames of wire, said Mr. Boys, of various geometrical patterns, dipped in soap solution and taken out, were found to carry film patterns of exquisite beauty, but always so that three films met at equal angles in a line, or six in a point, and this was the essence of the structure of froth. Large bubbles joined together in groups of two to half-a-dozen showed the same features on a larger scale. Such multiple bubbles, or single large bubbles containing just enough gas to float and no more, were interesting when turned adrift out of doors, more especially in a town. The reflections of the sky-line from the large spherical surface, or of sunlight from the large plane coloured interfaces, were alike surprising and beautiful. "Dream" portraits might be photographed by reflection from spherical or hemispherical bubbles. In order to blow big bubbles it was best to make use of the injector principle, as so much air and so little pressure were needed. The bubbles blown with the two hands and mouth at the opening of the first lecture were blown in reality by an injector action at a speed far beyond that at which the lungs could supply the air. Even bellows were poor things by comparison. An injector, with a tangential inlet, worked by foot-bellows, was made use of, as also a small motor-driven fan intended for drying ladies' hair. With either of these, very large bubbles could be blown quickly, and a little gas being introduced at the same time, they were made to support themselves and float away.

The electrically-driven hair-drier was also used to make a vertical stream of cold air, which, if strong, would carry a soap bubble away to a great height, or keep a couple of ping-pong balls floating in the stream of air. When the speed of rotation was reduced by the use of a Ferranti lamp-dimmer in the electric circuit, soap bubbles, either alone or in rings, would remain balanced in the air stream like the ping-pong balls until they broke. On turning the three-way switch in the handle of the hair-drier so as to send the current into the heating coils, a stream of hot air, or warm air, could be made, and when bubbles were blown with this, being warm, they were lighter than air, and ascended like fire balloons; but, presently cooling, they came down again, when they could be arrested in their descent by the stream of air, and sometimes the lower half could be introverted into the upper half.

Experiments with bubbles, such as blowing out a candle with the issuing air, floating one on the vapour of ether, and burning the vapour issuing from a bubble lifted from the ether, were shown.

The increase of the tension of a soap film in the presence of ammonia was shown by placing a bubble in a ring and holding a wet stopper above it, when it immediately shrank away from the stopper and slipped through the ring, or by holding a wine-glass containing weak ammonia below, when it escaped again, as though annoyed by the smell. When the bubble was too big to go through the ring, the efforts

Hosted by Google

were visible, and then a tear formed and hung from the bubble.

The series of experiments with bubbles one inside another, which are described in the new edition of the book on "Soap Bubbles"* by the lecturer, which the S.P.C.K. have brought out this week, were then shown, including those on the effect of electrification.

The short time remaining was devoted to experiments on the colours of soap films and celluloid films, winding up with Brewster's gorgeous experiment of a soap film made to spin by the impact of a jet of air (for which the hair-drier was again used). This gave rise to expanding eyes of colour of great brilliance.

On the motion of the Chairman, Lord Sanderson, G.C.B., K.C.M.G., a vote of thanks was accorded to the lecturer for his interesting course.

THE ROYAL SOCIETY OF ARTS.†

By Sir Henry Trueman Wood, M.A.,
Secretary of the Society.

VI.—The Premiums.
(1754–1851.)

As previously mentioned, the sole original object of the Society was to promote art, industry, commerce, and invention, by granting rewards and premiums for meritorious discoveries and inventions, for success in the various branches of the fine arts, painting, and sculpture, for increasing the economic resources of the kingdom by the import of new or little known materials of industry, or for developing those resources by new or improved methods.

The Society took infinite pains to prepare a list of suitable objects for its premiums. Each year the list was carefully revised. Some items were omitted, either because the offered award had been made, or because it had elicited no response. Fresh items were constantly added, and changes made in the terms of those which were not dropped. And besides the specified articles in the list, the Society was ever ready to consider any suitable application, so that it constantly made grants for things entirely outside its own proposals, so long only as the object was deemed worthy.

At first only money prizes were proposed. These varied in amount, and were, in many cases, really grants-in-aid rather than complimentary prizes. After a while it was suggested that such prizes, when of a complimentary character, might take the form of medals, and in 1756 Henry Baker proposed that the Society should give "gold and silver medals as honorary premiums, with a view of exciting emulation among the nobility and other persons of condition, with whom pecuniary premiums could have no weight." The matter was referred to a committee, upon which sat Hogarth, Nicholas Highmore, James Stuart, Thomas Hollis, and William Chambers. The committee discussed the question before them for about two years, and at last decided upon a design by Stuart. The medal was made by Thomas Pingo, the famous die-sinker, and it remained the chief medal of the Society during the whole of the first period of its existence. Copies of the medal struck in gold were at once given to the President, Jacob Viscount Folkestone, and to Robert Lord Romney, Vice-President, both "for eminent services"; one also went to William Shipley "for his publick spirit, which gave rise to the Society," and another to James Stuart "for designing the honorary medal of the Society." Later, gold medals for services rendered to the Society were presented in a good many cases. A few years after this it was decided to give honorary rewards in the class of polite arts in the form of a silver palette, and the first award of this palette was in the year 1767.

The classes under which the awards were arranged varied from time to time, but eventually they were distributed among six committees:—

1. Polite arts.	4. Mechanics.
2. Agriculture.	5. Chemistry.
3. Manufactures.	6. Colonies and trade.

The subject-matter with which the different committees dealt is sufficiently indicated by their titles. "Polite arts" included painting, drawing, sculpture, die-sinking, designs for manufactures, and also, to a certain extent, literature. Agriculture included forestry. Mechanics and manufactures were at one time dealt with by one committee, but were afterwards divided. Chemistry was industrial chemistry only, but comprehended also other branches of applied science. Colonies and trade was practically restricted to colonial matters. Besides, there were at various times other Committees, such as those on Correspondence, on Miscellaneous Matters, etc.*

* See "Notes on Books," p. 231.

† The previous articles of the series appeared in the *Journals* of June 9th and 16th, September 22nd and 29th, and November 3rd, 1911.

* "Agriculture" and "Colonies" have already been dealt with. "Polite Arts" will be treated separately. All the other subjects are included in the article, of which the first part now appears.

Hosted by Google

At first a number of members were appointed on each of these committees. At a later period this practice was abandoned, two chairmen were elected at the annual meeting for each committee, and it was left to those members who thought fit to attend.

The practice seems to have been that a general notice was sent round to those who were in the habit of attending the committees, and also to other persons, who were not necessarily members of the Society, known to be interested in, or conversant with, the subjects which were to come before the meeting. The whole proceedings were conducted with a good deal of formality. Any communication which was received was referred by the Secretary to the committee to which it seemed appropriate—the committee consisting, as above shown, of a certain number of persons who might be considered as more or less experts, and of any members of the Society who liked to attend. The candidate for the premium was also invited to be present to give such an account of his invention as he thought proper. After he had given his own version, and had replied to any questions which were addressed to him, the subject was discussed, first in his presence, and then after his withdrawal. Formal resolutions were then put as to the award to be made, and this recommendation was submitted to the next ordinary Wednesday meeting of the Society, when it was generally confirmed, but in some cases disapproved. If any award was made, the paper was generally referred to the Committee on Papers, with a view to its being inserted in the next volume of *Transactions*, if suitable.

It is thus evident that a great deal of trouble was taken to ensure a fair adjudication of the premiums. But it must often have happened—and, indeed, from the records it is evident that it did, at all events, sometimes happen—that the committee were by no means competent to deal with the invention, especially if it was of a new and original character. The committee must also, in the nature of things, have generally been composed of amateurs, who, however well-meaning and hard-working they might be, were sometimes incapable, and, in all cases, naturally biased by their own opinions. On the whole, however, it may be said that no one who makes a careful investigation of the awards made—and probably there are not very many who would care to undertake such a task—can fail to be of opinion that a genuine effort was made to do justice, and that in a great majority of cases fair justice was done. As a matter of fact, it is quite certain that most of the awards leaned to the side of generosity. But while a great many undeserving inventions were rewarded, there are not a great many which were rejected and which afterwards proved themselves of any value.*

The first actual premium list issued was that of 1756, and this only exists in manuscript. The first printed list is the second issued, and that is dated 1758. From that date the lists were issued annually. Till the publication of the first volume of *Transactions*, in 1783, the lists were issued separately; from 1783 they were included in each volume of the *Transactions*, besides being printed separately. The Society's set of lists before 1782 is, unfortunately, not complete, a volume in which the lists from 1763 to 1767 inclusive were bound up, having apparently at some time been lost. A separate copy, however, of the list for 1764 has been preserved. A partial list for 1765 and the complete list for 1766 are printed in the *Museum Rusticum*.† The British Museum set is complete from 1758 to 1781 inclusive.

After 1829 many changes were introduced in the lists. The importance of the Society's prizes was much diminished, and the character of its work was changing. The lists were shortened. Sometimes the offers of prizes were in general terms instead of for specific objects. From 1843 to 1847 the list was only issued every other year. With the grant of the Charter in 1847 the Society's system of prize-giving practically came to an end. Special prizes were offered and awarded from time to time, but the practice of issuing a general list of subjects for awards, though it was not formally abandoned, was really obsolete. A sort of attempt to renew it was made in 1863,‡ when a list of the old character was published in the *Journal*. The last such list appeared in 1873, but no awards were made upon it, and in practice the whole system had been defunct for at least a quarter of a century.

The first lists of awards made by the Society are contained in Dossie's "Memoirs of Agriculture," in which they were published by the Society's authority. The list down to the end of 1767 (exclusive of "Polite Arts") is given in the first (1768) of Dossie's three volumes

* A full and detailed account of the method adopted in making the awards will be found in the address delivered by Arthur Aikin, at the distribution of awards by the Duke of Sussex, as President. in 1817.

† Vol. V. p. 90; Vol. VI. p. 339.

(page 3). The complete list of the awards in "Polite Arts," to the end of 1776, and the other awards, from 1768 to 1776 inclusive, appear in his third (1782) volume (page 447).

The same list was also published by the Society in 1778,* and in a few cases where the two lists differ it may be assumed that the Society's list is accurate. There are very few discrepancies. There is yet another list, down to 1770, given in the "Description of the . . . Machines . . . in the Repertory of the Society, etc.," published by William Bailey, the Registrar of the Society in 1772.†

In the second volume of the *Transactions* (1784) a list is given of the awards from 1775 to 1782 inclusive. This list is by way of being a continuation of Dossie's lists, though, as a matter of fact, the two overlap as regards the years 1775 and 1776. From this date onwards the awards are given year by year in the annual volumes of the *Transactions*, down to what is really the last volume of the series, that for the session 1843–4, Vol. LV. In the interval between the cessation of the regular *Transactions* and the commencement of the *Journal*, lists for the years 1845 to 1850 were issued, and all of these are extant, that for 1847 being in MS. only. In 1851, the year of the Great Exhibition, there was no distribution of prizes, on account of the exhibition, and consequently no list. In 1853 there was a meeting for the distribution of prizes, and a list was printed in the *Journal*.‡

The premium lists were advertised and circulated as widely as possible. At one time the Society received a little official help in obtaining publicity for its work, for in 1775 the Postmaster-General sent a copy of the list to the local post offices, with instructions to the postmasters to let all persons coming to their offices have an opportunity of reading it.

An examination of the old prize lists, especially those between 1760 and 1800, affords an interesting indication of the state of scientific and industrial knowledge at the time. Naturally, we now possess a great number of the things for which the Society then offered prizes. Some of these offers produced good results, some were abandoned as utopian, though the machines or articles asked for are now commonplaces of industry and manufacture. Some of the proposals show what our modern conceit may regard as lamentable ignorance, others afford evidence of considerable shrewdness; others, again, indicate a quite natural incapacity to realise the direction of future progress.

That in the lists so many familiar names are missing is certainly disappointing. One would like to have found the names of Watt, Hargreaves, Crompton, Roebuck, Arkwright and Cort, amongst those whose inventions were recognised and rewarded by the Society of Arts. But in the early records none of these names appear. Why is this? The best reason that can be suggested is that all these men were in advance of their time. Like all great inventors, they had to wait for recognition until they had overborne the opposition of ignorance and of rival interests. When recognition came, it was too late for the prize or contribution which would have eased the early struggles. A committee which could anticipate the direction in which industry or science would progress would have to be composed of men with prescience beyond their fellows, and they would not have received the acquiescence or approval of their contemporaries.

It has always been so throughout the history of invention. The great inventor must, of necessity, be a man with ideas ahead of his contemporaries. He has never had their sympathy or their appreciation. On the contrary, he has always had to struggle against their active opposition. If his invention, as has generally been the case, has for its prime object the substitution of mechanism for human labour, he incurs the violent hatred of those who can only realise that their livelihood is being taken away from them.

The history of the introduction of textile machinery, by which millions of operatives now make their living, is a record of the attempts of the progenitors of these operatives to wreck the new machinery, and, if possible, to murder the man who designed it. As long ago as 1710 the Spitalfields weavers rose in riot and smashed their frames in protest against the introduction of improvements. A hundred years later, in 1816, the Luddite riots—after the wholesale destruction of factories and machinery in the Nottingham district—were only suppressed by the stern expedient of hanging a number of the ringleaders.

In the first half of the nineteenth century the hatred of new machinery was combined with strikes, often justifiable enough, for better pay, but certainly for nearly three centuries—since

* "Register of Premiums and Bounties," 1754–1776.

† This is a quarto volume with a collection of fine illustrations in folio. In 1782 another edition was issued by A. M. Bailey, who succeeded his father as Registrar in 1773. It is in two volumes, folio. In this second edition, the list of premiums is not carried beyond 1770.

‡ Vol. I. p. 365.

James Lee invented his stocking frame in 1589—the workers of the textile trades have done their very best to prevent any improvement in the tools of those trades. If the spinners and weavers had had their own way, all yarn would now be spun by the spinning wheel and woven on the hand-loom. The artisan fought for the ancient system of economic organisation, for domestic industry and handwork. Forces were too strong for him. The growth of capital and its systematical industrial application conquered in the end, but only after a long struggle against excusable ignorance and natural incapacity to appreciate the inevitable.

And the opposition did not come from workmen alone. Manufacturers a hundred and fifty or two hundred years ago, were no more anxious to change all their methods and scrap all their machines, than they are now. When an invention had proved its value, and had been taken up by the more enterprising manufacturers, the rest had perforce to follow suit, but in the meantime the original inventor had had but a poor time of it, and in all probability had died a pauper.

Nor did the inventor as a rule get much sympathy from the general public, or even from those members of the public who might have been expected to know better. After some centuries of mechanical and scientific progress we have perhaps learnt the lesson. Nowadays we are so accustomed to the rapid multiplication of scientific inventions that we readily accept any marvel, however marvellous. Yet there can be hardly any great invention which has not been condemned or depreciated by a competent and well qualified authority. The working of the same spirit may be traced from the beginning of the industrial revolution down to our own day. When Dr. Lardner demonstrated beyond cavil that no steamship could carry coal sufficient to take her under her own steam to America, the statement was accepted as the opinion of one of the best authorities of the time. The heads of the Admiralty declined to consider the use of the electric telegraph because the excellent and efficient semaphore arrangement fulfilled all their needs. We might have had mechanical transport on roads fifty years before it was accomplished, but for the opposition—partly interested and party ignorant—to the early constructors of road locomotives. A year or two before the incandescent filament lamp was perfected the best authorities were agreed that the "subdivision of the electric light" was impossible. The internal-combustion engine found but small favour amongst the older mechanical engineers (there was one brilliant exception). The idea of a "rotary steam-engine" was regarded with derision before the steam-turbine was perfected. The members of the old Aeronautical Society were for years looked upon as harmless visionaries. When the first paper on the basic process of steel-making was offered to the Iron and Steel Institute, the council of that body, a competent tribunal if ever there was one, declined to accept it.

Other instances might be cited, but these may serve to show the value of contemporary opinion on new discoveries, and the extreme difficulty of forming a sound judgment as to the direction which future progress in the application of science to industry is likely to take.

What can we expect if we go back a hundred and more years into a non-scientific age, when men were beginning dimly to realise the value of machines, and to recognise that the processes which had for centuries been wrought by human hands alone might possibly be aided by inanimate mechanism if it were only possible to devise it? What wonder, then, if those who were most anxious to improve the manufactures and industries of their country could imagine no better means than to reward small improvements in the crude existing appliances, and could not imagine a development which astonished their successors, or foresee an advance which we, a century later, regard with wonder and admiration?

Another reason which prevented the Society from taking cognisance of many important inventions was the regulation which excluded patented articles. In one of the earliest lists of Rules and Orders—that for 1765—it was expressly laid down that "No person will be admitted a candidate for any premium offered by the Society who has obtained a patent for the exclusive right of making or performing anything for which such premium is offered." This rule continued in force until the year 1840.

So strong was this feeling of opposition to patents carried that it was at one time proposed to require every prizewinner to agree not to take out a patent, but this proposal was negatived. In later years, when patents became more numerous, the restrictive effect of this rule became much more injurious than in 1765 (in which year only fourteen patents were granted), but even at that time it shut out many valuable improvements. However, the notion that the grant of a patent was an injurious restriction on industry, only to be condoned if the public could not get the benefit of a useful invention unless

Hosted by Google

it bribed the inventor with a monopoly, survived long after the end of the eighteenth century. Indeed, it was only in our own generation that the value of protection by patent was fully realised, and that—to quote once more an often-quoted saying of the late Sir William Siemens—if an invention were found lying in the gutter, it would be worth while to assign it to an owner who would have an interest in looking after it. Of course, this general statement, like all such statements, has its exceptions. Some inventions do not need a foster-mother. A case in point is that of the safety-lamp, for which Sir Humphry Davy refused to take out a patent. The need was so urgent, its fulfilment so complete, that no advocacy or advertisement was wanted. But the invention of the safety-lamp was exceptional, not only in this respect.

On the whole, we should admire the amount of useful work done by the Society's premiums rather than cavil because it did not accomplish more. What it really did effect may be judged from the following selection of the more interesting or more important of the subjects to which its energies were devoted. The task of selection has been by no means easy. Its successful accomplishment would demand an amount of technical and expert knowledge to which the present writer can make no claim. The examples chosen out of a century's work may, however, show how much was really accomplished, and how much those earnest industrial pioneers effected who worked in the name and on behalf of the Society of Arts.

The period covered is just a hundred years, from the foundation of the Society to the 1851 Exhibition. Of this period the first half was by far the more fruitful, and it is really to this half that our attention must principally be directed. By the expiration of the eighteenth century the system of prize-giving had practically fulfilled its work. It gradually became less and less effective till at last it died out. The work of the Society tended in other directions. For some years the Society languished; indeed, it nearly collapsed, to be revived again in the middle of the nineteenth century. The record of these changes is, however, a matter for future consideration. For the present we are concerned only with the history of the useful work effected by the Society during that first prosperous portion of its career, when its sole aim and object was the awarding of premiums for the promotion of Art and Industry, and the discovery of suitable objects for such awards.

Of all the inventions upon which, at the time when the Society commenced its work, the advance of industrial progress principally depended, the most important were certainly those dealing with the generation and application of motive power, and yet it was not to these inventions that most attention was directed. If those who devoted themselves to this department of the Society's work were unconscious of the impending change shortly about to be effected by the substitution of mechanical for animal power in every branch of industry, it is not to be wondered at. The modern steam-engine and the Society of Arts were almost absolutely contemporaneous. James Watt began his scientific career in the year in which the Society was founded, though it was eleven years later that he conceived the idea of the separate condenser, and four years later still (in 1769) that he took out his first patent.

In 1754, the need for some agency which could drive heavier machinery than could be worked by a man or a team of horses was hardly existent, and almost wholly unrealised. Yet it must, to some small extent, have been in men's minds, and we may find evidence for this in the desire to improve those elementary methods for utilising the known natural forces, wind and water, which showed itself in the work of the earliest engineers—millwrights, as they were called—and in the technical literature, such as it was, of the time. Amongst other places, we find it in the Society's premium list. The list for 1759 contains two offers of £50 each, one for a tide-mill, and one for an improved windmill, which should more effectively utilise the force of the wind than previously existing forms, and should also, with varying wind-velocity, communicate a uniform motion to the mill-shaft. As a result of these offers, several rewards were paid, one for a tide-mill going to the Rev. Humphry Gainsborough,* a brother of the painter, who seems to have been an inventor of considerable ingenuity. These and similar offers were repeated from time to time during the next fifty years, and various sums of money were paid for improvements in windmills and also in water-wheels. Dr. Erasmus Darwin corresponded with the Society at one time about his idea of a horizontal windmill, but no award was made to him. It is some time before the steam-engine makes its appearance in the list. In 1780 we find a gold medal offered for an engine for "working at one time, the greatest

* He was a friend of R. L. Edgeworth's, who says that he had never known "a man of a more inventive genius."—Edgeworth's "Memoirs" (1821, Second Edition, p. 153).

Hosted by Google

number of looms, not fewer than three." The offer was continued for some time, but there is no record of a prize ever being awarded. As a matter of fact, the first recorded use of the steam-engine in a factory is in 1786. Cartwright's power-loom was brought out in 1785, and was driven by steam in 1790. John Austin of Glasgow, also claims, in a communication to the Society,* to have constructed a power-loom in 1789, and to have had one running in 1798 at Pollokshaws, near Glasgow. He adds that, after this, a building was constructed to hold two hundred of his looms at the same mills. He received a gold medal from the Society in 1806. It is probable that the first to invent a power-loom was John Kay, whose patent of 1745, taken out jointly with Joseph Stell, included, as Kay himself says, "tape lomes to weave by water."† No description, however, of Kay's loom is extant. Kay was, at all events, indirectly the inventor of the power-loom, because it was his fly-shuttle that enabled a mechanical movement to be substituted for the action of the human hand.

Up to the end of the century references to the steam-engine are rare. A vague offer of a reward for "increasing the force or quantity of steam" in steam-engines was published in 1783, and long kept its place on the list, but it elicited no response. Would a modern triple-expansion engine or a turbine be eligible for the prize? They utilise the energy, but cannot be said to increase it.

The first substitution of mechanical power for handwork in the timber trade in England is certainly due to the Society. A premium for a saw-mill was awarded to James Stansfield in 1761, and sums amounting in all to over £300 were given to him to help him in improving and working his mill. By the instrumentality of the Society, Stansfield was also introduced to one Charles Dingley, who found the capital for setting up a mill at Limehouse, which was driven by wind-power. This mill, after working a short time, suffered the usual fate of all mechanical improvements, and was destroyed by a mob, but the owner was compensated, the rioters punished, and the mill reinstated.‡ For his services in the matter, a gold medal was awarded to Dingley. The backward state of English industry is shown by the fact that saw-mills worked by water and by wind had previously been in existence on the Continent, and even in America, though there seems reason to believe that Stansfield's was an improvement on the older types.

That eccentric mechanical genius Richard Lovell Edgeworth received several rewards. The most important of these was a gold medal awarded in 1769 for various inventions communicated to the Society. What these were, it is not very easy to say. It is just possible that one of them was a proposal for a steam carriage, which seems to have arisen out of a suggestion by Dr. Erasmus Darwin, who was a friend of Edgeworth.*

This, however, is not mentioned by Edgeworth himself, who, in his "Memoirs,"† enumerates only a carriage with springs and a new form of frame, a waggon "divided into two parts," a cover for haystacks, and a turnip cutter. He also says that he afterwards submitted a dynamometer, and from a letter of his it appears that he suggested a new form of camera-obscura.

For his "Perambulator, or instrument for easily measuring land," he had a separate silver medal in 1767. The idea of using a wheel for the purpose was not novel. Such an apparatus was known in the seventeenth century, and was called by the same name. Edgeworth's machine consisted of a wheel, or rather a framework of spokes without a tyre, to the axle of which was fitted a long screw projecting horizontally. A nut loosely fitted on this screw was prevented from revolving with it, when the wheel was run over the ground, by a suspended weight, so that the motion of the wheel caused the nut to travel along the screw, one thread for each revolution, and the distance traversed was thus indicated. The apparatus would, no doubt, be effective, but it must have been clumsy, and rather inconvenient to work. The circumference of the wheel was to be one pole ($5\frac{1}{2}$ yards).‡ In the "Memoirs" he states (p. 171) that the instrument worked with great accuracy, having run over a measured mile twice with a difference of only one inch between the two results. Edgeworth's eldest son Richard also received a silver medal in 1778, "for early mechanical genius shown in the constructing several models and machines." As he was born in 1765, he must have been about thirteen years old at the time. This reward seems to have remained unique.

Hosted by Google

The award of a gold medal in 1770 to Abraham Staghold for a screw-jack is of peculiar interest, because the jack, which is figured and described by Bailey,* is identical with the well-known modern implement, which, many years after Staghold's invention, was the subject of a patent. The vertical screw is operated by a worm-wheel working thereon as a nut, which worm-wheel gears with a horizontal worm driven by a winch-handle. Abraham Staghold was a blacksmith of Maldon, in Essex, and appears to have been a man of considerable inventive ingenuity, for he was also the inventor of the gun-harpoon, for which he received a grant of twenty guineas in 1770. His inventions, however, do not appear to have brought him a fortune, for in 1774 he sent in a petition to the Society, "desiring relief in his state of distress." The Committee on Correspondence were unable to recommend the Society to devote its funds to a charitable purpose, so the unlucky inventor got nothing by his application.

The first award for a gun-harpoon was followed by several others. For many years the Society continued to offer prizes for improved forms of the apparatus, and they also spent over £100 in experiments and tests.

As soon as a satisfactory weapon had been obtained—and this involved many details both in the gun and in the harpoon—they continued to offer rewards for whales taken by its use. One of the recipients of these grants, Captain Humphrey Foord, of Hull, wrote a very interesting account of his experiences with the new weapon, and made several pertinent suggestions for its improvement. He concludes his letter with a quite unnecessary apology for "the blunders of an illiterate tar, who is unacquainted with writing to the great."

Up to 1792 something like £400 had been expended, but after this the number of claimants diminished, and though the offer was not discontinued till 1821, the awards made in later years were few and the amounts paid inconsiderable.

Scoresby, in his history of the northern whale fishery,† gives an account of the Society's efforts to introduce the use of the gun-harpoon. He says that the weapon was invented in 1731, and was used with some success. "Being, however, difficult and somewhat dangerous in its application, it was laid aside for many years. In 1771 or 1772, a new one was produced to the Society of Arts, which differed so materially from the instrument before in use that it was received as an original invention." On the whole, Scoresby says, in spite of the great improvements resulting from the Society's premiums, "on account of the difficulty and address requisite in the management of it, and the loss of fish, which, in unskilful hands, it has been the means of occasioning, together with some accidents which have resulted from its use, it has not been so generally adopted as might have been expected." Later on, still further improvements were made, and at the date of Scoresby's writing (1820) it was coming to a certain extent into use. At the present date, under the different conditions of the whale fishery, the gun is always employed, to the practical exclusion of the old hand weapon.

Just about the end of the eighteenth century a great deal of attention was paid to the subject of mechanical telegraphs.* The first suggestion for such a method of conveying intelligence was made by Robert Hooke, who described, in a paper before the Royal Society in 1684, a method of exhibiting signals to be observed through a telescope, which, though rather complicated, might have been perfectly efficient had it ever been put into practice. The credit of making the first practical telegraph may be assigned to R. L. Edgeworth, who, as has been already mentioned, received several prizes from the Society. There is, however, no evidence to show that he submitted his telegraphic system to the Society. He says in his "Memoirs" that his attention was first drawn to the subject by a bet that he could report in London the result of a race at Newmarket before it could be brought by mounted messengers. Later on he described his method in the Transactions of the Royal Irish Academy (Vol. VI. 1795). In his system it was proposed to use four triangular pointers, each pivoted to the top of a mast, and representing units, tens, hundreds, and thousands, the precise figure being indicated by the position of the pointer. These numbers corresponded with words or sentences in a vocabulary.

The mechanical telegraph, however, was first introduced by a Frenchman—Monsieur Chappe—about 1794. Several lines of his telegraph were set up, and it was regularly used for military purposes. According to his system, six discs

† "The Arctic Regions," by W. Scoresby (1820), Vol. II. p. 227.

* *Rees's Cyclopædia*, Vol. XXXV. (1819) has a very full and excellent account of mechanical telegraphs. Most of the Society's awards are mentioned.

Hosted by Google

were mounted side by side in a frame in such a way that either or all of them could be turned edgeways, so as to be practically invisible, or vertical so as to be seen. By various combinations of these discs a great number of signals could be sent. For use at night, lamps were substituted for discs. A practically similar arrangement was submitted in 1805 to the Society by J. Davis, and he received a silver medal for it. Two other awards were made by the Society in 1808—a silver medal to Major Le Hardy for a rather ingenious device for indicating numbers by means of index discs capable of being set in different positions on a polygonal frame, and a silver medal to Chevalier Edelcrantz, a Swede, for a telegraph composed of vanes or shutters capable of being turned edgeways.

Two awards made in 1809 are also worthy of notice, because they refer to methods of hand-signalling. In one of the communications Lieutenant James Spratt, who was wounded at Trafalgar, describes a method of signalling by a handkerchief held in different positions; and in the second, Knight Spencer submitted what he termed an "anthropo telegraph"—a method of signalling by different positions of the arms.

The device, however, which superseded all of these was that invented by Admiral Sir Home Popham, which received a gold medal from the Society in 1816. This was a semaphore arrangement, in which two masts were employed, each with an arm capable of being set up at any desired angle to the vertical. It was by this apparatus that information was transmitted from Portsmouth and elsewhere to the Admiralty, until it was at length superseded by the electric telegraph. This was the apparatus with which Barrow (not yet Sir John) was so well satisfied, that when Ronalds in 1816 offered to the Admiralty his pith-ball telegraph, which was really the first practical electric telegraph, Barrow, then Secretary to the Admiralty, wrote, with his compliments to the inventor, "that telegraphs of any kind are wholly unnecessary, and that no other than the one now in use would be adopted." This historic communication is dated August 5th, 1816.*

The list of awards connected with mining is not a very long one. There were a few inventions for raising water from mines, the most important of these being William Westgarth's hydraulic engine, for which a gold medal was awarded in 1769. Nearly twenty years later, in 1787, a silver medal was presented to Smeaton, the great engineer, for a description of the apparatus which he communicated (after the inventor's death) to the Society.* Smeaton had a very high opinion of the value of the apparatus which, he said, was much appreciated in the Cornish tin-mines. Various methods of raising minerals were also rewarded by the Society, and described in the *Transactions*. All of these became obsolete when the steam-engine was applied to that purpose.

In 1816 a gold medal and 100 guineas were presented to James Ryan for his system of mine ventilation. Galloway† speaks in terms of high commendation of Ryan's system, which was to drain off the gas by "passages or gas drifts so arranged as to collect and draw off the gas at the highest level." It was largely introduced into Staffordshire, where it suited the character of the coal measures, but in the northern districts, where it was less available, it met with less approval and was not adopted.

The first person to provide miners with a fairly good and safe light was Dr. Clanny, of Bishop Wearmouth. He devised various forms of lamps into which air was forced by a bellows, its exit being controlled by valves of various device. After working for some time at the subject, he described one form of his lamp to the Royal Society in 1813. In 1815 he submitted an improved form to the Society of Arts, and received a silver medal, while in 1816 he was awarded a gold medal for a steam safety-lamp. These various devices were undoubtedly valuable and of practical utility, but they never came into general use. They were soon quite superseded by the safety-lamps of Davy and Stephenson, both of which were invented independently in 1815.

Civil engineering also hardly received its due meed of attention from the Society. The Duke of Bridgewater in 1800 received a gold medal in recognition of the great system of canals which he constructed, a well-deserved award, though, perhaps, it might have been more fittingly bestowed upon Brindley, the great engineer, whose genius was so wisely utilised by the Duke.

In 1788 a gold medal was given to Abraham Darby, for the iron bridge he built over the Severn, near Coalbrookdale. This was the first iron bridge ever constructed. The beautiful model which Darby presented to the Society is now in the Victoria and Albert Museum.

The award in 1762 of fifty guineas to G. Weldon for a machine for planing cast-iron

* *Transactions*, Vol. V. (1787), p. 181.

† "History of Coal Mining" (1882), p. 135.

Hosted by Google

is of interest, because it seems likely that this is the earliest true planer of which there is any record. No picture or description of the machine has been discovered in the Society's records, but Dossie* says that "It planed large iron plates as effectually as a common plane does boards; making curled shavings, and completely smoothing the surface of the plates."

As might naturally be expected, a good deal of attention was paid by the Society at the end of the eighteenth and the beginning of the nineteenth century to questions of naval construction. The old records of the Society show that it was frequently consulted by the naval authorities on questions of timber for use in building the King's ships, and such information as the Society could furnish was readily supplied. Some important awards were made by the Society in the class of naval architecture. In 1759 a prize offered for "Ships' Blocks," that is to say, models of ships of new construction, was awarded to Joseph Aldridge, and in 1804 a gold medal was voted to Robert Seppings (afterwards Sir Robert, and Surveyor of the Navy) for his invention of suspending instead of lifting ships in dock.† For this Seppings was granted £1,000 by the Admiralty. It was the first of many important inventions which gained him the reputation of being the greatest naval architect of his time. It was he who first introduced the extensive use of iron in the construction of ships, which, by the additional strength provided by his diagonal braces and trusses, prevented the arching of their keels, technically called "hogging," which always occurred when ships were laid by. Although in the use of iron for shipbuilding he had been partly anticipated by T. Roberts (Assistant Surveyor to the Navy)—who in 1808 received the Society's silver medal for "attaching the end of the beams of ships to their sides by iron instead of wooden knees"—it was Seppings who really revolutionised the art of shipbuilding by the extended use of iron framing. The "Howe," launched in 1815, was the first ship built entirely on Seppings's system, although it had been partially applied before that date.

As may be supposed, a great variety of mechanical and engineering inventions besides the few mentioned above received awards from the Society. In the first half-century of its existence these included corn and other mills, canal locks, dredgers, cranes, pile-driving machines, carriages of many sorts, a packing press, tools of many descriptions, mechanical movements, locks, clocks and watches, etc.

Later on, in the early years of the nineteenth century, most of the mechanical inventions submitted to, and rewarded by, the Society, were of a minor character, though many of them were valuable. The offer of a prize for an original screw brought out several methods for obtaining one, but not of the accuracy required for astronomical and other scientific purposes. There were many awards for improvements in clocks and watches, devices for cutting wheels for watches, watch-springs, etc. The prizes connected with lathes and turning were also numerous, including chucks, self-centring and other. Various mechanical appliances and devices now well known and familiar were brought out by the Society's awards, and descriptions of them will be found in the pages of the *Transactions*.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

THE CARBONISATION OF COAL.

By VIVIAN B. LEWES,

Professor of Chemistry, Royal Naval College, Greenwich.

Lecture IV.—Delivered December 18th, 1911.

THE POSSIBLE IMPROVEMENTS IN CARBONISATION.

If we distil coal at a fixed temperature, as has been pointed out, we know that in the distillates we have the volatile products yielded at all temperatures below the one employed, and such secondary products as have been formed by further decompositions, or by interactions between the primary products at or below that temperature; so that if we distil coal in bulk at the lowest temperature at which volatile matter can be driven out from the coal, the analyses of the products will give us the maximum of primary products with the minimum of secondary, and we shall obtain the best possible data for forming an opinion as to the composition of the coal, on the one hand, and the course taken by

the interactions and decompositions, on the other, in the secondary actions.

In the experiments that led to the introduction of coalite it was found that 420° C. (800° F.) was the lowest temperature that could be employed successfully, and many thousand tons of coal have been distilled at about this point, say from 400° to 500° C.

Under these conditions a fair gas coal, containing 30 to 33 per cent. of volatile matter, will yield 68 to 70 per cent. of low temperature coke, containing 10 to 14 per cent. of volatile matter, and a volume of gas varying from 5,000 to 5,000 cubic feet, according to the coal used, having a composition approximating to :—

Hydrogen		27·5
Saturated hydrocarbons—		
Methane	48	
Higher Members	10·1—58·1	
Unsaturated hydrocarbons		3·0
Carbon monoxide		7·3
Carbon dioxide		2·5
Nitrogen		1·6

The gas before iron purification contains about 1·8 per cent. of sulphuretted hydrogen.

The low temperature gas of course varies with the coal used, and the hydrogen is often below 18 per cent., and the saturated hydrocarbons up to 68 per cent., but the marked feature of the gas is that it contains hardly any benzene vapour, and owes its illuminating power to a small percentage of ethylene, and chiefly to the gaseous members of the paraffin series (mostly ethane), and also that the percentage of hydrogen per ton, and in most cases averages twenty gallons.

The low-temperature tar is as distinctive in its characteristics as the gas. It has a specific gravity of about 1·075, is very liquid, and contains an abundance of light solvent oils, very low aromatic hydrocarbons, very little phenol but large quantities of cresol, no naphthalene, and very little anthracene, whilst the free carbon is as a rule below 2 per cent.

The very low percentage of benzene in the light oils is made up for by the presence of paraffins, such as hexane, heptane and octane, whilst there are also present considerable quantities of that curious group of hydrocarbons known as naphthenes or hexahydro-benzenes, which play so important a part in Russian petroleum.

As before mentioned, carbolic acid occurs in very small quantities, but its higher homologues, such as cresylic acid, etc., occur in much larger quantities than in coal tar; and there are also present quantities of polyhydric phenols, or other esters of the type met with in coal tar, which form resinous masses difficult to investigate. The pitch left as a residue amounts to about 40 per cent. of the tar, and is of very fine quality, owing to the practical absence of free carbon.

A very complete investigation of this low-temperature tar has been made by Mr. J. S. S. Brame in the laboratories at Greenwich, and will be published elsewhere.

The average tar yielded by the coal gave on distillation the following results :—

Specific gravity 1,073

Distillation on 2,274 c.c. (0·5 gallon).

		By volume on tar.	Specific gravity.	Volume of hydrocarbons.	Tar acids recovered.
Water		2·64			
Light oil	to 170°C	3·10	·844	3·10	
Carbolic oil	170°—225°	13·72	·959	8·62	4·8
Creosote oil	225°—240°	8·35	·9885	4·64	3·1
Creosote oil	240°—270°	8·35	·9923	5·45	2·55
Anthracene	270°—300°	8·80	1·029	6·60	1·76
Anthracene	300°—320°	12·31	1·033	8·80	3·10

Pitch, by weight on volume . . . . 41·71

Bases recovered . . . . 1·32 per cent.

is low, very rarely reaching the amount present in the above sample, whilst bisulphide of carbon likewise is very low.

This I pointed out in the last course of Cantor Lectures which I gave in March, 1908, and it has since been confirmed by the work of Porter and Ovitz, White Park and Dunkley, and Burgess and Wheeler.

The tar also varies with the coal used, and is sometimes as high as twenty-three gallons

Light oils— percentage distilling below.			Calculated on Tar.	
100°C	15·6 by volume		0·55	
120°	31·2		1·09	
140°	54·7		1·91	
170°	82·8	100·0	2·90	3·10
over 170° and loss	17·2		0·20	

The ammonium sulphate amounted to only 12 lbs. per ton of coal, the temperature being too low for large production.

Hosted by Google

From these results it seems more than probable that the primary products of decomposition of the coal are those which are produced during the actions taking place in its formation, *i.e.*, methane, carbon dioxide and water, plus those compounds formed by the rising temperature and consisting of the first nine or ten members of the paraffin series, naphthenes and oxygenated hydrocarbons like cresylic acid. The action of heat upon these starts at once secondary reactions, and gives us gaseous and liquid compounds identified in low-temperature gas and tar, whilst at higher temperatures these in contact with the highly heated coke envelope of the decomposing coal undergo further actions, analytic and synthetic, and becoming diluted with poor gas from the residual pitch left in the coalite, yield the high-temperature coal gas and tar.

When coalite that has been formed with the evolution of 5,000 cubic feet of 22 candle-power gas, as measured by the No. 2 Argand, is further heated to a high temperature, it evolves nearly as much gas as it did before, and the composition of this gas is approximately:—

Hydrogen	71·13
Saturated hydrocarbons	18·26
Unsaturated hydrocarbons . . .	0·52
Carbon monoxide	6·30
Carbon dioxide	2·09
Nitrogen	1·70

The gas is practically non-luminous when burnt alone, but has a heating value of 447 B.Th.U.

It seems clear from these experiments that in the distillation of coal for gas, there are three distinct sources which give the final product:—

1. The primary gases evolved from the coal, and distilled out as the advancing temperature travels through the mass.

2. The gas evolved by the decomposition of the heavy tar or pitch left in the coking mass.

3. The gas produced by secondary actions, and contact of the primary gases and vapours with the hot coke and walls of the retort.

It now becomes possible to trace roughly the actions taking place in the destructive distillation of a gas coal. Up to about 450° C. the products are chiefly primary (see table below).

About 400° to 450° C. the secondary actions start, the saturated hydrocarbons split up into unsaturated and simpler members of the saturated series, the hexahydrides shed hydrogen and give aromatic hydrocarbons, the tar thickens and alters in character, and synthetic actions start, cresol and hydrogen form more toluene, carbolic acid and carbon yield carbon monoxide and benzene. About 900° C. the degradation of all the hydrocarbons and other oxygenated bodies is proceeding, and finally the mixture of the results of endless actions and reactions yields us the high-temperature gas and tar, the mixture being diluted with the carbon monoxide, hydrogen and methane yielded by the decomposition of the pitch residues in the soft coke, which leaves the hard coke behind.

All our carbonising processes, from the horizontal retort to the latest oven or chamber process, are smirched with the same defect, and that is the after-effect of heated surfaces and red-hot coke on the gas.

I have elaborated in much detail the fact that there is not a single factor of uniformity in our ordinary methods of carbonising, and there never can be with most of the proposed new processes. The coke-oven manager is in much the same plight, but he does achieve to a great extent what he is aiming at, and that is, to keep all the carbon he can in the coke. The gas-manager's aim is just the reverse; he desires all the carbon he can obtain in the gas, and few of the proposed methods of carbonisation go the right way to secure it. Indeed, the only approach to it is in continuous carbonisation.

No matter what temperature is used—the heats may be pressed as high as the material of

	Humus Bodies.		Resin Bodies and Hydrocarbons.
Carbon . . .	Water Carbon monoxide Carbon dioxide Hydrogen Methane	Gases . .	Methane. Ethane. Propane. Butane.
Coke and pitch .	Watery tar . .	Liquids . .	Pentane. Hexane. Heptane. Octane. Nonane. Hexahydrides. Oxygenated hydrocarbons, like cresylic acid and more complex bodies.

Hosted by Google

the retorts and flues will stand—the temperature of the distillation of the coal will be the lowest temperature at which it evolves gas, and if one looks back to Lewis Thompson Wright's classical work on the influence of temperature on carbonisation, it will be found that the coal fed into a retort at the highest attainable temperature gives for the first ten minutes a rush of gas having much the same composition as coalite gas:—

	Time after commencement of Carbonisation.			
	10 minutes.	1 hour 30 minutes	3 hours 25 minutes.	5 hours 35 minutes.
Hydrogen	20·10	38·03	50·68	67·12
Methane	57·38	44·03	35·54	22·58
Hydrocarbons	10·62	5·98	3·04	1·79
Carbonic oxide	6·19	5·98	6·21	6·12
Carbonic acid	2·21	2·09	1·49	1·50
Sulphuretted hydrogen	1·30	1·42	0·49	0·11
Nitrogen	2·20	2·47	2·55	0·78
	100·00	100·00	100·00	100·00
Carbon density of hydrocarbons	2·86	3·11	3·38	2·29

which at this temperature is capable of producing 1,200 cubic feet of gas, leaving 300 cubic feet to represent the volume gained by degradation of gaseous hydrocarbons and deposition of free carbon, of which the high temperature tar contains 25 to 35 per cent.

It may be taken in round numbers that when 11,000 cubic feet of gas are obtained per ton of such a coal, 45 per cent. of the volume is from the low temperature distillation; 42 per cent.

It will be seen that not only is the gas driven off in the first ten minutes of the charge nearly identical in composition with coalite gas, but also that the gas yielded in the last period of carbonisation is nearly the same as the gas obtained by the further distillation of the coalite, whilst during the intermediate five hours of the charge the gases evolved have been mixtures of the primary gas in various conditions of secondary change diluted with the residual gas from partially coked coal on the exterior of the charge, the secondary changes being brought about by contact between the primary gas, the tar vapours, and the wall surface, passage through the skin of red-hot coke, and radiant heat.

With a good Durham coal capable of yielding 11,000 cubic feet of gas and ten gallons of tar per ton when distilled under ordinary conditions, at a temperature of about 1000° C., it is found that on carbonising at 600° C. it yields only 5,000 cubic feet of gas, but 22 gallons of tar per ton, and the residue, on continuing the distillation at 1000° C., yields a further volume of 4,500 cubic feet of gas, but no tar; so that removing the gas first formed and the tar vapour from the secondary reactions induced by high temperature has reduced the gas yield by some 1,500 cubic feet per ton, and increased the tar yield by 12 gallons, and an examination of the tar shows that the 12 gallons gasified by direct distillation at high temperature consist of the lighter portions of the whole of the tar, from the residues left in the low-temperature coke distilled at a high temperature; 13 per cent. from the various secondary actions and tar.

When tested by the No. 2 Argand, the low-temperature gas has a candle-power of 22, the gas from the pitch in the coke is nearly non-luminous, giving not more than 2½ to 3 candles, but when mixed with the rich gas in the proportion of 45 of the latter to 41 of the former it gives a 16 to 17-candle gas, whilst the gas from the tar and the secondary action is 10-candle gas when tested alone, and when mixed with the others brings down the total candle-power to 14 to 15 candles.

In the new methods of carbonisation, where the makes approximate to 13,000 cubic feet, the improvement found is entirely due to the free escape without over-heating of the products from the first two-thirds of the coal carbonised, whilst the extra volume is obtained from the complete degradation of the products from the remaining third, and that this is so is shown by the methane in the gas. In all fair coal gas in which there has been no over-degradation, even if you have been getting 11,500 cubic feet per ton from light charges, the methane will be about 34 to 35 per cent. of the gas, but notice the products of the new carbonisation, and you will find plenty of samples with only 28 per cent., and some even lower.

In considering the ultimate effect of pushing temperatures to the highest possible extent, it is well to consider the amount and value of the

Hosted by Google

gas and coke that could possibly be obtained from an ordinary coal:—

If we took a coal of the consumption—

Carbon	80
Hydrogen	5
Oxygen	10
Nitrogen and ash	5

and were to carbonise it in an inverted vertical retort with the coal fed in by a ram at the bottom, so that the gas and vapours had to traverse a column of 10 ft. of coke at 1000° C., contact would decompose all the gaseous and volatile compounds to hydrogen and carbon monoxide, and we should obtain:—

Coke.	15·27 cwt.	
Hydrogen	22,400 cubic feet	= 77·87 per cent.
Carbon monoxide	6,366 ,, ,,	= 22·13 ,, ,,
	28,766	

that is, you would rather more than double the volume of gas, but it is a non-luminous gas of the same thermal value (gross) as water-gas, and not worth more than the 3½*d.* to 4*d.* a thousand, that you could make water-gas at by one of the newer processes.

Certainly you get an increase in the quantity of coke, and it would be an excellent metallurgical coke.

Now, this is exactly what is done in all the new processes directly the cool passage for the escape of the primary gas gets tar-logged, and the gas from the remaining coal is driven through the red-hot coke and along the sides of the retort. Under these conditions some 3,500 cubic feet of 22-candle gas are obtained, whilst there is a free cool passage for its escape, and after that is closed the remaining coal yields by complete degradation of the tar and hydrocarbons 9,500 cubic feet of hydrogen and carbon monoxide, and you take a pride in your 13,000 cubic feet, instead of being heartily ashamed of it.

Of course, there is the saving factor that between the good primary gas and the relics of ruined hydrocarbons there is a good deal of only partly destroyed gas from the coal and tar near to the mouthpiece, so that the make averages out at 15 candles, and the cool distillation of the tar from the first two-thirds of the coal yields two-thirds of the 20 gallons that would have been obtained had it all been distilled in the same way, and this is the secret of the new process, tar being 13 to 14 gallons per ton more liquid and more paraffinoid in its nature.

In continuous carbonisation it is claimed that degradation does not take place, but the make and the methane in the gas tell their own tale, and the fact that the charge is always fairly cool in the top three feet of the retort, and is of nearly the full breadth of the retort, is made up for by the rapid tailing of the uncarbonised portion, which soon makes the cool inner core an impossibility, whilst it must be tar-logged for a considerable distance.

During the past few years a perfect tornado of results from every kind of carbonising process has burst upon the gas world, and as the same class of coal has hardly ever been used, and as the experimental methods have differed even more widely than the coal, the results, as a basis of comparison between the various processes, have been for all practical purposes of little or no use.

In order to obtain from these results something like a comparison, I have taken the figures obtained by the most practised observers, and have translated them by comparison into terms of a good North-Country gas coal, carbonised to give a yield of 15 candle-power gas, as tested on the Metropolitan No. 2 burner, and having a thermal value of 540 B.Th.U. gross, taking the results to the nearest 500 cubic feet:—

Gas Make.

Horizontal 6-hour charges.	Horizontal 12-hour charges.	Intermittent verticals.	Continuous Carbonisation. Woodall-Duckham.	Continuous Carbonisation. Glover-West.	Chamber Carbonisation.
11,500	13,000	13,000	13,000	13,500	12,500

that is to say, the horizontal retort, well filled, gives yields equal to the intermittent verticals, or Woodall-Duckham continuous verticals, and is superior to chamber carbonisation, being surpassed only by the Glover-West continuous vertical retorts, which owe their superiority to the engineering skill with which the various parts are designed and to the regeneration of the secondary air.

When we take the four leading systems and try to differentiate between them by the important item of fuel consumption, we find the best practice gives per 100 lbs. of coals carbonised:—

Horizontal.	Intermittent verticals.	Continuous Carbonisation. Woodall-Duckham.	Continuous Carbonisation. Glover-West.
14	15	12·1	10·3

So that here, as one would expect, the withdrawal of heat from the coke, and utilising it to heat the

Hosted by Google

secondary air, gives the Glover-West process an advantage.

If we now take cleanliness of working, amount of nuisance to the neighbourhood of the gas-works, and uniformity in composition of the gas during the period of carbonisation, the continuous vertical retort stands alone.

It is an impossibility to shoot or feed a heavy charge of raw coal into a red-hot retort without getting an outrush of steam and smoke that permeates the atmosphere for a considerable distance, and means not only loss but stench, whilst they also give the further advantage that the coke being cooled in the bottom chamber of the retort needs little or no spraying when drawn, and steam is thus avoided.

The coke, tar, and sulphate of ammonia in all the new methods of procedure are an improvement upon the products from the lightly charged horizontal, so that not only from the scientific but also from the practical point of view the continuous vertical retort processes are the ones that show the real advance, and, what is still more important, they are the ones which offer a promise of improvement.

There are other points, however, which the gas-manager must take into consideration in choosing a process, and these are the cost of an installation, the cost of labour, and the ground space that the installation will occupy.

At present the cost of the vertical retort installation, be it intermittent or continuous, is in most cases just about double that of the horizontal; but, on the other hand, it must be credited with saving in labour and space, nor should it be overlooked that the horizontal retort had had a century of experience lavished upon it, whilst the vertical is in its infancy.

I think I have said enough to show that in my opinion we are well ahead of Continental practice, and if anyone asked my advice as to his present carbonising methods, it would be to use full charges in horizontals until a scrapping of the plant becomes a necessity, and then to instal a continuous vertical retort system.

The ideals to be aimed at in a perfect carbonising process are a uniform treatment of every particle of coal distilled, a uniform treatment of the whole of the gas evolved, and, what is perhaps as important as anything, preventing the degradation of valuable hydrocarbons by contact with hot coke or other surfaces.

I have shown the limitations of the various processes, and there can be no doubt in the minds of those who have studied the question that the continuous vertical retort, when properly proportioned and worked, gives the only solution of the problem of uniformity in treatment to coal and products alike, and if scientific teaching is of any value, they must be the type of gas-making retort in the future.

That, however, is not saying that I consider the two present systems perfect or anywhere near it. Already experiments are being made in several directions to find further improvements. You will have noticed that I have said nothing about such installations as the Glasgow verticals, simply because it would not be fair to discuss them at present.

I have my own ideas as to the lines on which to work in the future, but before I place them before you I want to discuss another side of the question of carbonisation from the gas-manager's point of view, which must be placed in the front as a policy if gas is to do the work I hope for it in the future.

The limit of volume in gas-making, if not already reached, is fast being approached; economies are day by day getting more difficult to make, coal is not likely to cheapen, and all this means that the chance of considerable reduction in the price of gas is getting less and less. If the price of gas could be reduced in our large cities to the price charged at Widnes, the consumption of gas could be economically increased and for power and heat gas would hold an unassailable position, but this can never be done under existing circumstances, because even if the gas could be made at the necessary price, the increased output of coke would outrun the demand; if, however, the companies would only live up to their titles of "Gas Light and Coke Companies," and bestow as much care on the coke as on the gas, and cater for the supply of a good domestic fuel at the price of coal instead of treating coke as a by-product, the demand for it would soon reach a point that would enable the desired reductions in the price of gas to be made. There is no need to fear as to the other by-products; the output of sulphate of ammonia could be doubled without affecting the market, and a good tar will look after itself. It was high heats that ruined the tar market, and with the demand for tar increasing for road work, no flooding of the market need be feared.

During the last few years the statement has several times been put forward that "as the gas-manager's end and aim is gas, it is his duty to obtain the greatest volume of gas possible per ton of coal," but with this I venture to disagree. The gas-manager's duty is to obtain the greatest possible value per ton of coal, and

Hosted by Google

until every industry dealing with coal recognises that in this respect their aim is the same, little economy will be possible in our rapidly diminishing store of coal.

The pressing of temperatures in carbonisation to higher and higher degrees with the old conditions of lightly charged retorts has given larger yields of gas, but it has loaded the gas with carbon bisulphide, depreciated the coke, and ruined the tar; and one of the chief claims for the adoption of the full charge horizontals and intermittent vertical retorts for carbonisation is that they have improved the character of both coke and tar.

As I have shown, this is due to a certain proportion of the gas and tar vapour coming off through the cool core, and so escaping over-cracking, but it can be only a partial improvement, whilst, as far as the coke goes, the nearer it approaches metallurgical coke the less it is fitted for a domestic fuel. True it is that where the coke has been made harder and brighter the gas-manager's market has improved, but it has been for use in furnaces, manufacturing processes and for producers that the increased demand has been felt, and not for domestic use.

Even for the heating of the furnaces the coke made at extreme temperatures is not as good as when the heats were slightly lower, and in Germany this is beginning to be recognised, and Körting, in a paper read this summer, points out that the inclined settings, which used to work with 12 per cent. of fuel, now require fully 16 per cent., an increase due partly to higher temperatures, but largely to more highly carbonised coke.

Already the strides forward which gas has made as a domestic fuel are telling the tale in our atmosphere, and the yellow fogs of the last century are getting rarer, and if coke could be made a domestic fuel by leaving in it 6 to 8 per cent. of volatile matter to facilitate ignition and give a flame, the gasworks of the country could command the fuel market.

Remember that the sale of gas cannot be pushed beyond a certain point without over-stocking with coke, the sale of both *pro rata* must be pushed, and if only you could be persuaded that this is the right road, you would be backed up by the smoke reformers and the public, and find yourselves able to sell a fuel coke at the price of the best coal.

I have shown that the factor for which you ruin your coke as a domestic fuel is about 3,000 cubic feet of gas of the same value as blue water gas, the 3,000 cubic feet of gas left in the coke would be worth four or five shillings a ton on the selling price, and the cost of replacing it by water-gas would be about one shilling, whilst the creation of a large domestic market would enable a reduction in the price of gas to be made that would still further increase its use as a fuel.

Now, I am sure in my own mind that these are the lines the gas industry should consider seriously, and that the advances in the next ten years must be an endeavour to get nearer to the ideal of carbonisation, and to improve both gas and coke; and having shown you the object I have in view, let me give you my ideas as to how I think it may best be done.

The modern forerunner of the vertical continuous process was, as I have already pointed out, the Settle-Padfield retort, which I tested at Exeter seven or eight years ago, and with the principle of which I was immensely taken, and which gave splendid results. Its passage, however, from the experimental to the practical scale, as in so many cases, proved its undoing, but on looking up a notebook of that date, I find that I obtained the following results:—

Coal used—poor slack, No. 4 Cammerton.

Make per ton	Gas	13,250 cubic feet
	Illuminating power	14·72 candles (London Argand)
	Heating value	533·7 B.Th.U.
	Tar	none
Same coal in horizontal retort	Gas	9,862 cubic feet
	Illuminating power	15 candles

The Settle-Padfield process consisted of a semi-vertical or, if I may call it so, boot-shaped retort, much of the same design as now used in shale distillation. The vertical portion was about six feet in length, and the inclined part at the bottom three feet, the junction of the two portions being the weak part of the apparatus, as it was liable to crack, thus leading to infiltration of furnace gases, which was discovered when the gas given in the above test was analysed. The leak was then made good, and further tests gave 13,000 to 13,200 cubic feet per ton of 15-candle gas. The outstanding feature of the process was that the upper 3 or 4 feet of the vertical portion of the retort were left empty, and that the coal was fed in at the top by a

Hosted by Google

plunger in charges of 2 to 7 lbs. per stroke as desired, and fell through the empty heated zone on to the red hot coke, where it was carbonised on the heated surface, the first run of rich gas rising straight up through a zone of radiant heat to the mouthpiece at the top of the retort. The weakness in this process was that the coke was allowed to accumulate, and was then at intervals removed through an ordinary oven door at the bottom of the incline, so that the " baking area " varied according to the amount of coke at the bottom of the retort. Had the retort been a plain vertical one, with an automatic coke remover working *pro rata* with the coal feed, it would have been the perfect embodiment of the true conditions for carbonisation, as the temperature needed only a little lowering in the superheating portion of the retort. The idea was to carbonise all the tar formed, so that if any condensed it was returned to the retort, and this phase of the subject is well worth discussion.

In the Settle-Padfield experimental retort, I should say, speaking from memory, that the temperature in no part of the retort was 1000° C., if so much, and yet at this temperature 13,000 cubic feet of gas per ton were made from Camerton slack, the gas tested in the London Argand giving 15 candles, which would have been 17·5 on the No. 2 Argand.

The same coal in a horizontal retort gave 9,862 cubic feet of the same candle-power gas, and ten gallons of tar per ton, so that the alteration in the method of carbonising and the tar, which if any formed was returned to the retort, gave a gain of some 3,000 cubic feet. The temperature of the lower portion, however, was insufficient to drive out all the more resistant volatile matter, and a very good coke was the result.

Now, what was it that caused that rattlejack old retort to give results better if anything than the beautiful models of constructive skill that we see in the two present continuous systems ?

In the first place, we all know the importance of a large ratio of heating surface to the mass of coal, and if you consider how the ground-up slack must have piled itself up on the top of the mass of red-hot material, heated from below, washed by the ascending hot gases from the last charge, and radiated upon by the sides of the red-hot retort above, you will see that the heating surface was far greater than in any other system, and instead of heat slowly penetrating to it, it was plunged, the moment it left the feed, into a red-hot area, which drove off a good deal of gas before even it reached the carbonising mass below, and deposited it, sweating tar, on the hot surface. The gases as they were disengaged rushed straight upwards to the exit without coming in contact with any surface to decompose them, the radiant heat being just sufficient to fix and get the best out of the tar vapour.

To many the idea of a heated space above the carbonising coal seems like going back to the lightly charged horizontal with the space that led to disaster, but they do not realise that radiant heat does little harm and much good, if there is not too much of it, and that it is contact with hot surfaces that is fatal. In the horizontal the gases rushed up to the top of the arch and were decomposed by contact, in a vertical space they rush to the cool top and exit pipe, hardly touching the sides, whilst the radiant heat performs such beneficent functions as breaking up the hexahydrides in the tar vapour into aromatic hydrocarbons and hydrogen.

Mr. W. G. Africa, in a paper read in October last at St. Louis, in relating his experience with vertical retorts, says that they got unusually high results as to candle-power by leaving a space of 4 feet of heated retort above the coal, thus fixing the vapours, which in full retorts do not reach the proper temperature for gasification.

Now, my idea of a perfect continuous system would be a vertical retort like the one that Glover first made, which had the space at the top, and fitted with a semi-intermittent feed and coke removal device, with the addition of the cooling chamber, with secondary air regeneration, the heat in the flues being concentrated on the outside of the retort at the spot where the coal falls on to the surface of the coke, as it is here that heat is withdrawn most rapidly; the temperature might then fade away above and below this area to, say, 800° C., and if properly regulated, 6 to 8 per cent. of the volatile matter of the poor gas-forming residues would be left in the coke to make a perfect domestic fuel, any shortage of gas being made up by blue water gas.

The volume of gas actually made from the coal might only be 9,500 to 10,000 cubic feet, but it would be rich in saturated hydrocarbons, and would probably stand dilution with 5,000 cubic feet of water gas to bring it down to statutory requirements.

In this way it should be possible to make more gas than at present and a valuable fuel, whilst we should have attained practically the ideal of carbonisation—uniformity.

It has always been felt by the gas engineer that tar meant a great waste of vaporised carbon, which, if it could be kept in the gaseous

Hosted by Google

form, would give an enormous addition to the gaseous products, and would represent a large proportion of heat and light. Experiment, however, has shown that the gasification of tar and tar oil is a most thankless task to undertake, and most gas engineers look upon it from the point of view taken by Lewis T. Wright—that tar is a child of high temperature, born in the heat of the retort, and so thoroughly acclimatised as to resist all further attempts to gasify it successfully.

As regards the chief portions of high-temperature tar—pitch, naphthalene, and the higher aromatic hydrocarbons—this is true, but, as we have seen, lowering the temperature of distillation increases the yield of tar, and it seems clear that a large proportion of it is due to primary action, and consists of paraffins, naphthenes, and other hydrocarbons, which would lend themselves to gasification, as well as the oxygenated and " cycle " derivatives which are more resistant, whilst naphthalene, anthracene, etc., are absent. It is evidently worth while to see how far tar of this character can be gasified, and whether it is economically better to do this than to utilise it for other purposes.

In the early eighties Mr. Lewis T. Wright made a number of experiments on the gasification of tar and tar distillation by passing them into a retort filled with lime and heated to 1100° C., and obtained the following results:—

Tar	10,700	cubic feet	per ton of	12·5	candle-power	gas
Crude Naphtha	10,130	,,	,,	20·5	,,	,,
up to	27,000	,,	,,	14·5	,,	,,
Light Oils	18,000	,,	,,	16·0	,,	,,
up to	30,000	,,	,,	13·5	,,	,,
Creosote Oil	13,300	,,	,,	14·0	,,	,,
up to	29,300	,,	,,	8·5	,,	,,

Now, tar in those days *was* tar, and not creosote oil, pitch, naphthalene, and free carbon, and yet on these figures it was decided that tar as a source of gas was " dear at a gift," owing to the ubiquitous naphthalene obstructions and troubles that followed any attempts at gasification.

I have made many experiments upon this subject, and the conclusions to which I came long ago were that tar, once obtained in the liquid state, could be utilised for the purpose of gas-making only in one of two ways:—

1. Distil off the naphthas, light oils, etc., which come over below 240° C., and gasify these, or

2. Inject the tar into a mass of incandescent coke, so as to break it up into hydrogen and methane, having a sufficient column of red-hot coke to filter off the deposited carbon.

If the ton of coal yields 20 gallons of 1·07 of gravity tar, it is found that 25 per cent. of it will distil below 240° C., leaving a residue perfect for road-making. The 25 per cent. of distillate represents about 50 lbs. weight, and on gasification will yield 10 cubic feet per lb. of 15–16 candle-power gas; and, therefore, by this method there is obtained an addition to the gas from the ton of coal of 500 cubic feet of good lighting and heating gas and 15 gallons of good road-making tar.

If, on the other hand, the tar be returned into incandescent coke so as entirely to decompose it, the 20 gallons will yield 1,500 to 2,000 cubic feet of a mixture of hydrogen and methane with oxides of carbon, having a thermal value of between 400 and 450 B.Th.U.

Taking the tar, even of the quantity and quality yielded by such a process, no economy is to be found in converting it into gas by any other than the most simple expedients of the same character as the one utilised by Settle, of simply returning it to the retort. This applies to tar after it has been condensed, and not to nascent tar in the gaseous state as it leaves the decomposing coal.

At the beginning of the last century, when Clegg, Malam, and others had grasped the importance of preventing the degradation of the gases by contact with hot carbon, and were trying to avoid it by carbonising in thin layers, it was commonly believed that if coal were distilled in layers less than two inches in thickness, no tar was formed. This, of course, is nonsense, as anyone can see by heating a gram of coal in the bottom of a test-tube, but under the conditions of their experiments none or very little came over, and the reason is the same that led to little or no tar being found in the Settle vertical retort.

In Clegg's rotary and web retorts a thin layer of coal was passing in a tray, or on a web, through a flat oven heated to a high temperature, which gave an enormous ratio of radiant surface to the weight of coal carbonised, and under these conditions the nascent tar vapours never had a

Hosted by Google

chance of condensing into the vesicular form found in the brown tar vapour leaving the retort; it was superheated instead of being cooled, and bore the same relation to brown tar vapour that superheated steam does to the condensing steam we see leaving the spout of a kettle. Catch it in this nascent state and heat will gasify it, but if it once cools to brown vapour, molecular condensations prevent it ever again being got in the gaseous state without almost complete decomposition, and even in the Dinsmore process, with which Mr. Carr was so enamoured, not more than 1,000 cubic feet per ton could be ascribed to its decomposition, as there was a fall in temperature before it entered the cracking duct or retort. The tar must pass direct from the coal into a temperature higher than that which gave it birth, but not hot enough to do more than gasify it, and if any important results are to be obtained from tar as a gas producer it will be on these lines, and carried out in a vertical retort, so that the radiant heat alone acts, and contact is reduced to a minimum; and this is one reason for the importance I place upon having an empty space of constant dimensions at the top of a continuously working vertical retort.

The economic advantage of gasifying tar is purely a question of the price it commands. Supposing the tar could be so gasified, and yielded 120 cubic feet of gas per gallon of 12 to 14 candle-power gas, it would not be worth more than 10*d.* per thousand in the holder, so that unless the price of tar is under a penny a gallon it would not pay to use it for this purpose.

In comparing the gas retort with the coke oven for gas-making the outstanding difference is one of heating surface, and of the size and condition of charge dealt with.

In the gas retort it is less than a ton of a fairly dry mixture of all sizes, and the thickness of the layer carbonised does not exceed 12 ins., and is generally far less, and is not compressed.

In the coke oven the charge may be anything up to 8 tons of damp, fine coal, and the thickness of the layer carbonised16 ins. to 30 ins., the charge being as far as possible compressed. Now, the important part in furnace coke-making is to provide a dense, hard coke, from which practically all volatile matter has been driven, and this means that for the full temperature of carbonisation (900 to 1000° C.) to reach the centre of the large mass of material, the time of carbonisation becomes three to five times as long as in the gas retort. Gas is evolved slowly, and therefore remains longer in contact with the red-hot coke; leakage is greater, and the ne result is that the gas yield may be averaged at 9,500 cubic feet of 10 to 12 candle-power gas, with a heating value of 540 B.Th.U.

So that it is clear that as a method of carbonisation for the production of gas it cannot compare with the retort, showing a shortage of 1,500 to 2,000 cubic feet of gas and 3 to 4 candles, whilst if, as is the usual practice, the poorer portion of the gas is used for firing the oven, the available gas amounts to only 4,500 cubic feet of 15 candle-power gas.

Now, the greatest argument which I know in favour of coke-oven gas as a town supply is that it has been adopted largely in Germany and America, neither country being open to the reproach of want of commercial shrewdness. But are the conditions under which it has been adopted the same as those existing in, say, London and Brighton? Is it not a fact that its adoption has been for areas close to colliery districts, where the conversion of smudge and smalls into coke was a necessity, in districts rich in metallurgical works, where foundry coke was a necessity; or in America, where the general use of slow-combustion stoves demands a hard, slow-burning fuel?

The claims of the coke oven as a means of making town gas are based on the economies of carbonising in bulk, and the increase in yield and value of the coke, reducing the price of the gas as made into the holder to a fraction of the 10–11*d.* a thousand it now costs; but if such a process were introduced in London, the make of coke would be enormously increased, and its quality of hardness and difficulty of burning would reduce instead of increasing the demand for domestic purposes; coke prices would fall, and the economies would be converted into a heavy loss.

At the present moment coke-oven gas is an impossibility for town supply, unless heavily benzolised, which is a mistake for a gas to be used with mantles, but under altered conditions of Parliamentary requirements it may well be that coke-oven gas will play an important part in lighting and power production in the North of England and other colliery districts; but I cannot conceive its ever being adopted where domestic fuel and not foundry coke is the chief requirement.

In a course of lectures such as these, four seems an ample allowance at the commencement and probably, to the audience, more than ample at the end; but I realise only now how miserably inadequate the time has been for the expression

Hosted by Google

of the matter I desired to bring before you, and can only hope that some of the points, controversial though they may be, will prove helpful in considering the carbonisation of coal.

POPULATION OF FIFTEEN PRINCIPAL TOWNS OF FRANCE.

The number of inhabitants of the principal towns in France (with populations exceeding 100,000), according to the census taken on March 5th of last year, has just been published.

The following figures show the present populations of the fifteen largest towns as compared with those of 1906:—

	1911.	1906.	Increase.
Paris	2,846,986	2,763,393	83,593
Marseilles	552,182	518,498	33,684
Lyons	524,056	472,114	51,942
Bordeaux	261,678	251,947	9,731
Lille	216,806	205,602	11,204
Nantes	169,254	163,247	6,007
Nice	163,833	134,327	29,506
Toulouse	149,044	149,438	(decrease 394)
St. Etienne	148,778	146,788	1,990
Le Havre	132,667	132,430	237
Rouen	122,420	118,459	3,961
Roubaix	122,154	121,017	1,137
Nancy	118,187	110,570	7,617
Rheims	113,372	109,859	3,513
Toulon	104,582	103,540	1,042

Although in many of these places the number of inhabitants has not greatly increased, Toulouse is the only one where it is less than it was five years ago. Nice, on the other hand, shows an increase of 21·96 per cent. in the population since 1906.

COMMERCIAL FISH CULTURE IN GERMANY.

Fish-breeding in ponds is carried on in practically all parts of the German Empire, especially in Silesia, Brandenburg, Hanover, Schleswig-Holstein, Westphalia, Lorraine, the Rhine Palatinate, Bavaria, Saxony, Baden, and Würtemberg. It is estimated that the total area of fish-ponds in the empire is approximately 185,000 acres, which is about ·14 per cent. of the total land area of Germany. The size of the ponds and the average amounts invested vary greatly, depending upon the general lie and adaptability of the land on the one hand, and upon whether or not fish culture is carried on as a principal occupation or merely as a side line in connection with rural industries in which ponds are more or less necessary. The average area of the ponds ranges from 1·35 acres in Bavaria and 1·57 acres in Saxony, both of which kingdoms are rather hilly and mountainous, to 12 acres in Silesia where the land is comparatively level. There are two general systems of fish culture in Germany, one for the propagation of carp and the other for the production of trout. According to the United States Consul at Berlin, carp require warm water and are generally bred in large, shallow ponds with little inflow. The perch, American trout, tench and eel are bred under similar conditions as carp, either in ponds, together with the carp, or separately. Carp ponds are usually such as may be drained, and are either allowed to remain empty during the winter or are planted in oats, wheat, etc., or lie fallow during alternate periods of one or more years. A complete plant for the cultivation of carp usually includes a small, shallow, warm-water spawning pond, a larger so-called "nursing" or stock pond, and a fattening pond. In the nursing pond the young carp from the spawning pond are placed at the rate of 200 to 700 fish per hectare (2·47 acres) of pond area. The number depends upon the size and age of the fish on the one hand, and upon the nourishing capacity of the pond on the other. In very cold regions the carp must be taken out of the nursing ponds during the winter season and transferred to a deep specially enclosed winter pond. The carp are allowed to remain in the nursing ponds one or two summers, depending upon whether or not they are to be marketed as "three summer" or "four summer" fish. They are then placed for one or two years into the fattening pond, in which 150 to 250 fish are allowed for each hectare. To transfer the carp, the pond must be drained and the fish collected in a pit located near the outlet. Carp growing may be extensive — that is without artificial feeding—or intensive, with artificial feeding. In the latter case a pond may be stocked with two to four times as many fish, and the yield in weight in marketable fish correspondingly increased. Artificial foods that are given to carp and similar fish are maize, vetches, rice, beans, potatoes, rape-seed, meal and sesame cake, bran, cooked grains, malt, fish meal, chopped meat, snails, etc. The second general system of fish culture, the propagation of trout, is comparatively much less important in Germany. Among the 10,255 acres of ponds in Schleswig-Holstein only 294 acres are trout ponds, and in Westphalia there are 57 acres of ponds for fattening trout and 391 acres for breeding stock trout. The proportion of trout-fattening ponds in the other divisions of Germany is not known, but it is probably no larger than in the two mentioned. Unlike carp, brook and rainbow trout and similar fish require colder water, and cannot stand a temperature over 64° F. They are therefore grown in small, shaded, cold-water ponds having a considerable in and outflow. Special spawning and stock ponds are generally not maintained. The artificial foods that are given to trout are cooked shell fish, fish and slaughter-house refuse, meat of horses and other animals, and fish meal, and specially prepared fish foods. The gross and net income derived from fish culture varies on the one hand with the natural productiveness of the pond, and whether or not this is supplemented by artificial

Hosted by Google

feeding, fertilising, etc., and on the other hand, with the cost of stocking the ponds. The profits of fish culture are also increased if the breeders can sell their product direct to the consumers. For this purpose fish-breeding associations are formed in all parts of Germany.

THE MINING INDUSTRIES OF YUNNAN.

The treasures of Yunnan lie not so much in its soil as under it. Travellers across the province have characterised it as the wealthiest district in China, but until more expert information, based upon prospecting, is at hand, judgment on this point may well be postponed. Enough is definitely known, however, to show that Yunnan has varied and valuable mineral deposits, and is entitled to the consideration of the mining world. The development of the mining industry in Yunnan has been hampered and restricted by numerous factors, among which may be mentioned an insufficient means of communication and transport, the lack of capital, and the inability of the people to co-operate in large undertakings. The development of the province will follow the development of the mines, not precede it; and the removal of the causes that have worked in the past against the opening and operation of the mines must be effected before any improvement in the mining industry may be looked for. The mining regulations reserve to the central Government 25 per cent. of the profit on all mines, plus an additional 20 per cent. in the case of precious stones, 10 per cent. in the case of gold, silver and quicksilver, and 5 per cent. in the case of coal and iron, and require all minerals to pay an export duty of 5 per cent. and a "likin" charge of 2½ per cent. The American Consul at Canton says that the tin mines of Kochin, in Mengtsz Hsien, supply between 4 and 5 per cent. of the world's production of tin. They cover an immense area and have been worked by the natives for centuries. The last decade has shown a steadily-increasing output. The mining population of Kochin, numbering about 30,000, constitutes, to all intents and purposes, a small world in itself. The right to work the mines adheres to the proprietors of the land, who can exercise it themselves or lease it. These rights are clung to with great tenacity. The whole industry is regulated by a committee of all the mine owners, which in mining affairs exercises an autocratic jurisdiction, and the miners, smelters, porters, etc., are combined in guilds of their own with full power over their members. The deposits occur both on the surface and beneath it, but surface mining has now been abandoned. The shafts are sunk in the hillsides at an angle usually of 45°, and are started at random, without previous test borings. The ore is for the most part ferruginous, with a slight tracing of lead. One British analyst found 50 per cent. of hematite and magnetite. Many of the shafts reach a depth of over half a mile, but from their horizontal direction require no ore-lifting apparatus. The shafts are, without exception, extraordinarily narrow and low, the roomiest in the whole district is only four feet high and a little over three feet wide. For miners, half-grown boys are in demand, as their greater agility and smaller stature are an advantage in these narrow galleries. The majority of the miners succumb at an early age to the unhealthy conditions which surround their labours. In some of the shafts an awkward attempt has been made to assist the circulation of the air by means of "wind boxes," or bellows, but even in these the atmosphere is foul and unwholesome. As a rule the ore is broken up at the mine's mouth and cleaned, and when it has reached a point where it contains 60 per cent. of tin, it is carried in baskets to the smelting ovens. There are some thirty of these ovens in Kochin, imperfectly constructed of clay bricks, at a cost of about £200 each. The bellows used are of wood, and each requires three men to work it. Ten men in all are required for each oven. The ovens are fired in November, and continued in use for three months. Charcoal is used for fuel. When the metal first flows with the slag into the retainer it is so impure that repeated recastings are necessary. It is not known how much metal is lost in the smelting process, but it is probably not less than 20 per cent. It has been stated that one oven will turn out between 1,500 and 1,700 pounds of tin a day, but these figures are, if anything, too low.

The process of refining cannot be carried on in Kochin to a very fine point, and when the slabs are placed on the market they still contain an appreciable quantity of other substances, principally iron and lead, which makes re-smelting necessary before pure metal is obtained. For many years the mines of Kochin have supplied the demand in China for tin for use in the national coinage, in the manufacture of "silver joss" paper burned at religious ceremonies, and in other industries. The recent substitution of silver dollars and fractional pieces and copper cents for the old-time brass "cash" has diminished the home demand for the metal, and a large share of the output of the mines now finds its way to foreign markets. The exportation of Kochin tin is controlled by the merchants of Mengtsz, who ship principally to their correspondents in Hong Kong. During the last few years a proposal to introduce foreign machinery has been discussed by the mine owners, but no decision has been arrived at. The extensive orpiment mines in Mengkwa and the Chaochow, are rich in ore. Coal is distributed throughout nearly the whole province. Copper, silver and lead have been mined by the natives for years in the north-east, and iron, zinc and quicksilver in other districts. The northern part of Yunnan is rich in salt wells, and supplies the principal demand for this commodity. The existence of gold has been inferred from the name Chin-sha Kiang, or River of Golden Sand, which the Yangtze bears in its course through north-western Yunnan, but the presence of gold deposits has not been definitely established.

THE PRODUCTION OF BALSAM OF PERU.

Balsam of Peru really comes from the Republic of Salvador, and the tree is found on the coast which extends along the western Pacific slope of Salvador between the ports of Acajutla and La Libertad, a distance of only about forty miles. Assuming that this strip has a depth from the coast of fifteen miles, there is an area of only seven hundred and fifty square miles at the most over which the tree is exploited. Balsam from Salvador has been called Peruvian for the following reason: The Republic of Salvador has a coast-line on the Pacific Ocean only, and from its ports must therefore be shipped all its products. If they go across the Isthmus of Panama, as has been the case for three hundred years and more, these shipments are confused with those from Peru in South America, hence balsam from Salvador was called Peruvian. The balsam tree is one of the most beautiful of a tropical forest. The trunk is cylindrical, the bark somewhat cracked, of a greyish or ashen colour, with whitish blotches due to the parasitic lichen that clings to it. The fruit is a pale, yellow, membranous, feathery pod, with only one seed as a rule. According to a report of the International Union of American Republics, balsam collecting is a very interesting work. Although the tree holds sap (*jugo*) at all seasons of the year, yet it becomes more abundant according as the season is dry, and consequently the summer is selected as the most favourable time for securing the crop (*cosecha* as it is called). The entire process, from collecting the crude sap to its final storage in metal cases for shipment abroad, is not all in the hands of one individual, but divides itself, like rubber gathering, into two procedures. When the dry season is assured, the gatherer selects his tree, and at the period of the young moon gets it ready. He first strikes or scratches the bark with a stone or other blunt instrument, girdling it in a peculiar fashion of his own. The bruise thus made is intended to detach the outer bark, but to leave the second, inner layer exposed. The hole thus made in the bark is called the window. From this tender portion of the tree there exudes, after a variable period of from five to eight days, the mature sap of the tree. The most popular method of obtaining the sap is to attach to the wound or "window" a piece of cloth of a size sufficient to cover it, and sufficiently absorbent to become impregnated completely with balsam. The cloth must be extremely clean, or otherwise the flow will not be steady, and the dirt on the cloth will make the further process an uneven one. At the end of eight to ten days, according to the weather, the flow ceases, and it must be again stimulated by a second irritation. This is accomplished by applying heat to the tree by means of a burning torch. Great skill is necessary in using this heat, to get just the right effect, for if the torch is applied too closely the balsam catches fire. Heat is applied every two months, and after each stimulus of this kind five or six cloths (*trapos*) are changed. A final collection of sap is obtained in some cases by scraping the wound and the various strata of bark down to the inner wood, and, after reducing this bark to a powder, boiling out the residue in water. A trick of the trade is the adulteration of the crude balsam by mixing with it an amount of raw sugar, or the charred husks of cacao diluted in water. The life of the balsam tree is about one hundred years. The gathering of sap is begun at the age of twenty-five years, and this sap may be gathered indefinitely, unless some accident to the tree occurs meanwhile. When the sap has been collected from one tree or a dozen of them, the pieces of cloth are loosened and at once placed in a kettle of water, in which they are boiled for half an hour. The pieces are then immediately, while quite hot, thrown into a primitive kind of press composed of a small-meshed net of coarse cord or braid in endless folds. As the cloths are squeezed, the sap exudes and settles to the bottom of the kettle beneath; the liquor on the top can then be poured off, and what is called crude balsam alone remains. The unclarified balsam is put in a vat beneath which a slow fire is kept burning. As the viscous liquid is warmed, the water is driven off by evaporation, and the organic impurities gather gradually on the surface. After the clarification is completed, the liquid is poured into rectangular tins, each containing about fifty-five pounds of balsam, and shipped as the well-known article of commerce to its European or American destination.

A GERMAN TREE-FELLING MACHINE.

A machine for felling trees has been invented in Berlin. The principle of the invention is that by pulling an ordinary steel wire rapidly backwards and forwards around the tree to be felled, sufficient heat is developed by the friction to burn a smooth groove through the stem of the tree. The American Consul-General in Berlin says that the inventor illustrates his invention by means of an ordinary steel wire about a yard in length, which is provided with a single handgrip at each end, which he pulls rapidly backwards and forwards around a chair or table leg, the wire thus burning a groove into the wood. In actual tree-cutting a smooth tensely-drawn steel wire, having a diameter of ·039 to ·118 inch and a length of about twice the diameter of the tree, is placed round the stem where the cut is to be made, and is fastened at each end by means of easily manipulated clasps to the two ends of a long steel cable or hawser leading to the readily transportable electric power machine. In the case of the harder wood varieties a wire with side projections is substituted for ordinary smooth wire, and in some cases a cable of two or more wires is used. Each of the two ends of the power cable or hawser passes, at the machine

Hosted by Google

end, through eyes in each end of a double-armed lever, from where they are brought together and passed through the hollow shaft in the centre of the lever, after which they are wound up together upon a pulley or windlass with a crank. In this way any slack in the cable may be taken up and the tension of the wire in cutting may be regulated. The double-armed lever of the power machine is driven backwards and forwards upon its central shaft by means of a driving rod from an eccentric wheel which rotates by motor power. The power cable and the wire are thus pulled backwards and forwards at the rate of 16·4 feet per second. In cutting down trees the cable is chosen long enough to make it possible to place the machine out of reach of the falling tree. The machines may also be used in cutting logs or timber already felled, in which case a shorter cable may be used. The power required for European varieties of wood ranges from 1·5 to 7 horse-power, depending upon the hardness and dimensions of the timber. A 4 horse-power machine is said to cut down a pine tree two feet in diameter in about five minutes. The Consul says that although the inventor has made demonstrations before the Government forestry and other officials, the authorities and timber interests have not as yet generally taken up the invention. Objections raised to the system are that it is expensive, and that with the occasional breaking of the wire and other delays no time is saved in the long run. Another objection is that, although it does cut down trees, the plane of the cut is never exactly straight, and the burning so chars the wood that the age circles as well as any knots and other defects are not easily distinguishable. On the other hand it is claimed that by washing the ends of the timber the rings, etc., may be readily made visible, and the charring and burning are said to preserve the wood where the cut is made.

HOME INDUSTRIES.

Miners and the Minimum Wage.—There is grave reason to fear that the miners are bent upon striking, and that there will be a two-thirds majority at the ballot in favour of a national stoppage. The men seem to be spoiling for a fight, and the employers are no longer disposed to make concessions, for they feel that they are fighting for the principle of the sanctity of agreement. They contend that the South Wales agreement of 1910, signed by them and the men, has three years to run, and prevents any such demand as that of the men being made now. The demand for the minimum wage did not become part of the definitely accepted policy of the Miners' Federation until the autumn of 1909, and in the opinion of many of the employers its acceptance would be a staggering blow to the coal trade. There are many estimates of the extent to which the output would be reduced, and some experts put it at not less than 20 per cent. Assuming it to be only 10 per cent., its effect upon the export trade must be very serious. And the minimum wage asked for, 8*s.* a day, is considerably more than the wage now earned at a majority of the collieries in Great Britain. Coming on the top of the burdens imposed by the Mines Regulation Act, and the Insurance Act, the enforcement of the minimum wage might well give our foreign competitors in the coal market an advantage that would be disastrous to much of our export coal trade. The output of coal in Germany and the United States is rapidly increasing, and their export trade with it, whereas we exported less last year than in any year since 1906. The loss of any considerable portion of our coal exports would mean enormous loss, directly and indirectly, to the country, and those who suffered most would be the miners themselves, for many collieries would be closed, and the men who cannot or will not earn the minimum wage would be dispensed with. It may be hoped that these considerations will ultimately weigh with the men sufficiently to induce them to abstain from a strike that would be disastrous to all concerned, but at the moment there is scant ground for hope.

The Cotton Position.—Messrs. Hubbard Brothers and Co. refer to the lock-out in the Lancashire cotton trade as a cause of the check in the foreign demand for cotton and the relapse in prices. They hold, however, that the determining influence was the unwillingness of spinners and "investors" to follow the advance from the lowest point beyond a given limit. "It is," they say, "a question this season of spinners providing themselves with a reserve supply out of the largest American crop ever grown. Cotton will be bought to take the place of the shortage in the India crop and in the yield of other countries, but the surplus will have to be carried by merchants and by spinners. A very large quantity will be carried against sales for forward delivery because the European spinners are willing to take a view of the situation for a longer time than for one season, utilising directly and indirectly the future markets for that purpose. Our own Northern mills have so far taken from this crop less cotton than last season; we do not hear of any who are acting upon the broad view of the Continental spinner and seeking to provide on the present comparatively low range of prices for cotton ahead. They appear to be waiting for that sharp decline which they have been expecting after the European had secured his supplies upon which to buy, but did not expect, nor in fact did anybody believe, that these foreign spinners would think of securing cotton for several years in advance because it was below the average price of the past five years. We see the extent of this forward demand in the premium paid for new-crop deliveries, when they usually sell at a discount at this season of the year. There is a better tone to the cotton goods business in America, which may be the forerunner of a demand to replenish exhausted stocks in the hands of retailers. Certainly, the fashions can only change in such a manner as to call for an increased consumption of cotton cloth."

Shipbuilding.—The year 1911 was a record year in Scotch shipbuilding. The statistics collected by the *Glasgow Herald* are very remarkable. They show that the tonnage output of all the Scotch yards last year was 357 vessels of 671,624 tons and 837,668 i.h.p. engine-power. The proportions of the several rivers were: Clyde, 413 vessels and 630,583 tons; Forth, 31 vessels and 11,319 tons; Tay, 31 vessels and 17,303 tons; and the Dee and the ports of the Moray Firth, 82 vessels (of the fishing type) and 12,419 tons. The Forth was about 2,000 tons, and the Tay about 12,000 tons up, but the Dee and the North were practically unchanged. The Scotch production made a gain in the year of no less than 257 vessels, aggregating 251,374 tons and 213,400 i.h.p. The mere increase in Scotland was more than the entire year's output of any country in Europe except Germany, and was almost equal to the entire output of the United States. These are interesting facts which illustrate the extraordinary character of the year. The Clyde output alone—that is, tonnage launched, which does not mean, of course, vessels completed—of 630,583 tons and 789,929 i.h.p., that is to say, the entire output as distinct from the increase, was in tonnage more than half as much again as the entire output of Germany and equal to the entire production of the rest of Europe. The Clyde production last year was only 30,000 tons less than the combined output of the United States and Germany, and it is 10,664 tons and 221,402 i.h.p. more than the previous record year, 1907. With the exception of Barrow, Liverpool, Middlesbrough and Stockton, all the principal shipbuilding centres share in the advance, and how greatly the United Kingdom is in advance of other shipbuilding countries is shown by the following comparison of the latest returns as to new construction (including sailers) recorded at Lloyd's:—

	Ships.	Tonnage.
United Kingdom	483	1,519,000
Germany	89	350,300
France	26	123,000
United States	59	105,800
Holland	45	79,700
Austria	11	62,100
Japan	35	22,000
Norway	43	21,700
Denmark	12	19,200
Italy	18	19,100
Belgium	6	14,200

Thus, the United Kingdom tonnage is more than four times that of Germany, while it only lacks 42,000 to make up the double of the tonnage of all the other countries combined.

The Port of Manchester.—Although during the second six months of 1911 the Manchester Canal suffered from serious and prolonged labour troubles —which led to sheds and quays being blocked with cargo which could not be got rid of because of the disorganisation of inland transit, and since then some of the railway companies have been unable to find railway waggons in sufficient numbers to clear the docks of the merchandise ordered forward by rail, with the result that much trade has been lost to the port through the inability to provide discharging berths, and the handling of the cargo has been done in circumstances which must seriously prejudice the financial result of the year just ended—the gross receipts of the Canal show some increase upon those of 1910, a little over £570,000 as compared with £555,735, and if the net revenue of the year shows little or no improvement, the check was due to special causes which have passed, and there is ground for the expectation that, given the absence of labour troubles, 1912 will show considerable improvement. The various regular steamship services of the port, both foreign and coastwise, have been well maintained during the year, and both importers and exporters are becoming more and more convinced that it is to their interest to use the Ship Canal. The quantity of foreign grain which arrived in Manchester during 1911 constitutes a new record, and the returns show an increase of about 45,000 tons over the figures of 1910, about 493,000 tons having been imported via the Canal. Of this, it may be interesting to note that about 131,425 tons come from India, 124,995 from Russia and the Black Sea ports, and 117,106 from the United States and Canada.

The Clothing Trade.—It is believed that the output in the wholesale clothing trade last year was the largest upon record. A feature of the year's trade has been the demand for measured goods, in itself a proof of the widespread prosperity of the working classes in 1911. When wages are low and irregular the demand is for the cheapest clothing that can be produced; when wages are high and steady the demand is for good clothing, as has been the case this year. The clothing industry is mainly a home trade, but during the past year shipments to South Africa, which is the chief oversea market, increased, and orders coming through at present are larger than they have been for some time past. The only thing likely to interfere with the prosperity of the trade in the current year would be a strike on a serious scale, for the clothing trade is the first to suffer and the last to recover from the effects of labour disputes.

Small Holdings.—It is pleasant to read of the success of the Small Holdings Act where it has been worked by a local authority in sympathy with its aims, and it has been possible to get suitable land. The new President of the Board of Agriculture has been visiting the estate purchased by the Northumberland County Council from Lord Ridley for the purposes of the Act. It contains 871 acres of arable land, and about twelve under wood, and the average annual rental is about 34*s*. per acre. The tenants speak very hopefully of their prospects, and there are nearly 400 applicants still waiting for land. The county council could absorb 20,000 acres if they could get them, and many of the

Hosted by Google

actual tenants are earning a livelihood out of land which was previously practically derelict. In another part of the county, an estate is in occupation of small holders, many of whom are miners who work the regulation eight hours in the pits, and give the remainder of the day to the cultivation of land and the breeding of stock. Labour underground seems to give the colliers added zest for farming operations. It must, of course, be remembered that the Northumberland men are some of the pick of their class, but the evidence accumulates that in all parts of the country workers are anxious to benefit by the Act, and that where men can get suitable land on reasonable conditions they are doing well upon it.

CORRESPONDENCE.

THE FISHERIES OF BENGAL.

I have read, with much interest, the remarks of Mr. Frank Birdwood on the above subject in the *Journal* of the 5th inst. The reason why the "Golden Crown" experiments were inconclusive is to be sought for in the policy of the official who succeeded Sir Krishna Gupta as "Commissioner of Fisheries." Not only were the "Golden Crown" results vitiated, but other investigations, such as the "Culture of Carp," the Sunderbuns survey, and the study of the spawning grounds of the Hilsa, were also, to a large extent, interfered with. What Mr. Wilmot Corfield said in the *Journal* of the 29th December, about the neglect of the "Golden Crown" fish after landing at Calcutta, is, unfortunately, too true.

At this time of day it would serve no useful purpose to enter into matters with which personal considerations are concerned. I can only reiterate that, in my opinion, a well-managed fishery company, to supply the Calcutta and other markets with fresh fish in ice, would be a profitable concern. It will give the speediest return on the smallest capital. If, afterwards, such matters as a cured-fish trade, or even steam trawling in the open sea be taken up, well and good; but allow me to advise, in the first instance, a cautious and careful consideration of the hundred-and-one factors which make for success in a large fishery company.

JAMES TRAVIS JENKINS.

NOTES ON BOOKS.

SOAP BUBBLES. By C. V. Boys, F.R.S. New and enlarged edition. London: Society for Promoting Christian Knowledge. 3*s*.

The large audiences of "Juveniles" of all ages, who have been listening to the lectures which Mr. Boys has just been giving at the Royal Society of Arts, and watching with delight his very beautiful experiments, will be glad to learn that they can obtain in a handy and inexpensive form a somewhat fuller account of soap bubbles, their colours, and the forces which mould them, than it is possible to give in the course of a couple of lectures. The book is written in the simplest style, so that a child of fourteen or fifteen, of ordinary intelligence, could easily understand it, and the apparatus for the experiments described is of a corresponding simplicity, nothing being required in many cases but a few pieces of glass and india-rubber tubing. It is, perhaps, hardly to be expected that the young physicists, however conscientiously they may follow the minute and practical directions in the volume, will achieve that wonderful success in conducting experiments which gives to Mr. Boys the appearance of a magician; but, without arriving at this degree of perfection, they may well find some pretty amusement for the holidays, while the charm of the subject may awaken some to the interest of a more prolonged and serious study of science.

The first edition of this book appeared about twenty years ago. The second and enlarged edition differs from the first in the addition to the old text of the description of further experiments and observations on the subjects there treated. There are, besides, five additional chapters on "The Soap Bubble," "Bubbles other than Soap Bubbles," "Composite Bubbles," "Out-of-door Bubbles," and "The Colour and Thickness of Soap Bubbles." The last is necessarily somewhat difficult, as the theory is given very fully and exactly, but without the use of algebra or trigonometry. The genesis of the colours is illustrated by means of a coloured plate, which also is stamped on the front cover. The chapter on "Out-of-door Bubbles" shows how pleasing an occupation may be derived from the use of soap bubbles in a garden on a summer day. This probably will be found the most interesting addition to the non-technical reader.

GENERAL NOTES.

LECTURES ON ILLUMINATING ENGINEERING.—A course of ten lectures on Illuminating Engineering will be given at the Northampton Polytechnic Institute on Tuesday evenings at 7.30 p.m., commencing January 16th, 1912. The lectures are intended for a technical audience, and each lecture will be given by a specialist in the particular subject. The subjects and lecturers are:—(1) "The Nature of Light and of Radiation," by S. D. Chalmers, M.A.; (2) "Photometry and the Measurement of Light," by A. C. Jolley; (3) and (4) "The Production of Electric Light and its Distribution," by F. M. Denton, A.M.I.E.E.; (5) "The Chemistry of Gas Manufacture and Lighting," by S. Field, A.R.C.S.; (6) "The Use of Shades and Reflectors," by S. D. Chalmers, M.A.; (7) "Physiological Factors in Illumination," by W. Ettles, M.D.; (8) "The Practical Use of Arc Lamps," by A. C. Plumtree; (9) "The Practical Use of Metallic Filament Glow

Hosted by Google

Lamps," by Val. H. Mackinney; (10) "The Practical Use of Gas Lamps," by W. E. Goodenough. The course is regarded by the Governing Body as a pioneer course; should it be as successful as its importance warrants, it will in subsequent sessions be developed into full special courses, including laboratory and other important ancillary work. It is intended for engineers, architects, medical men, representatives of public bodies, and administrators generally, as well as for general technological students of engineering. Full particulars of the course can be obtained on application to R. Mullineux Walmsley, D.Sc., Principal, Northampton Polytechnic Institute.

Bryan Donkin Fund. — The second triennial award of grants in aid of original research in mechanical engineering, under the Bryan Donkin Fund, will be made in February, 1913, when the amount available will be about £34. Applications should be made to the Secretary, Institution of Mechanical Engineers, Storey's Gate, S.W.

An Ordnance Survey for Tripoli. — A geographical mission to Tripoli, under the auspices of the Italian Government, has been organised by the Instituto Geografico of Florence. The expedition is under the command of Colonel Caputo, of the Staff Corps, and formerly professor at the School of War. Besides the necessary geodetic operations for the completion and revision of the existing maps of the country, it is intended to establish an astronomical observatory at Tripoli. It is also intended to fix the trigonometrical stations, which will eventually serve as bases for the triangulation of the country, the surveys of which will be made on the scales of one to 100,000 (·63 inches to a mile), and one to 50,000 (1·26 inches to a mile), the same as those of the ordnance survey of Italy.

Cattle-Rearing in Japan.—The statistics lately published by the Japanese Government tend to show that the rearing of cattle in that country is in a flourishing condition. The number of head of horned cattle, which was 1,261,000 in 1900, had increased to 1,297,000 in 1908, and to 1,350,000 in 1909. Horses, which numbered 1,542,600 in 1900, and dropped to 1,367,000 in 1905, on account of losses during 1905, had more than regained the former figure, and were 1,551,000 in 1909. The number of sheep in Japan is quite insignificant, and were only 2,400 in 1900 and 3,400 in 1909. The number of goats increased from 60,000 in 1900 to 87,000 in 1909. Pigs increased from 181,000 to 287,000 during the same period. The number of animals slaughtered for food in 1909 was as follows: cattle 178,000, horses 45,000, sheep and goats 7,000, pigs 161,000. The Japanese Government, with a view to encouraging the improvement of the breeds of cattle, etc., have established three model farms and a poultry farm. There are, besides, three establishments for the breeding of horses and stallions.

Platinum Production in New South Wales.—Although not one of the chief mineral products of New South Wales, platinum is found in paying quantities. It has been mined in the central part of the State, and the beach sands on the north coast have been treated for the metal. Up to the end of 1909 the total Commonwealth production was only 11,578 ounces, valued at £21,000, and nearly the whole of it was contributed by New South Wales. In 1910, 332 ounces, valued at £1,380, were won in New South Wales. For some years the price of the metal abroad has been rising, until at the end of June, 1911, it had attained the record price of £9 per ounce. This high price will probably lead prospectors in New South Wales to investigate more carefully the possibilities of platinum mining.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings, at 8 o'clock:—

January 17. — Cyril Davenport, F.S.A., "Illuminated MSS." Sir Walter Armstrong, Director of the National Gallery of Ireland, will preside.

January 24.—William J. Gee, "Hydraulic Separating and Grading." Robert Kaye Gray, M.Inst.C.E., will preside.

January 31. — Professor G. W. Osborn Howe, "Recent Progress in Radio-Telegraphy." Sir William H. White, K.C.B., F.R.S., will preside.

February 7.—Leonard Hill, M.B., F.R.S., and Martin Flack, M.A., M.B., B.Ch., "The Influence of Ozone in Ventilation."

February 14.—Cecil Thomas, "Gem Engraving." Sir Arthur John Evans, D.Litt., LL.D., F.R.S., will preside.

February 21.—Frank Warner, "Silk." Sir George Birdwood, K.C.I.E., C.S.I., M.D., LL.D., will preside.

February 28.—H. A. Roberts, M.A., "The Relations of Science to Commerce and Industry." Principal Sir Henry A. Miers, M.A., D.Sc., F.R.S., will preside.

Indian Section.

Thursday afternoons, at 4.30 o'clock:—

January 18.—The Rev. Walter K. Firminger, B.D., Senior Chaplain, Bengal Establishment, "The Old District Records of Bengal." Sir James A. Bourdillon, K.C.S.I., will preside.

February 8. — Colonel Sir Thomas H. Holdich, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc., "The North-East Frontier of India."

Hosted by Google

MARCH 14.—E. A. GAIT, I.C.S., C.I.E., Census Commissioner for India, "The Indian Census of 1911."

APRIL 25.—WALTER SAISE, D.Sc., M.Inst.C.E., Hon. Member Institute of Mining and Geology, India, A.R.S.M., V.D., "The Coal Industry and Colliery Population of Bengal."

MAY 16.—NEVILLE PRIESTLEY, Managing Director, South Indian Railway, "Indian Railways."

COLONIAL SECTION.

Tuesday afternoons, at 4.30 o'clock :—

JANUARY 30.—W. A. LEGG, M.Inst.C.E., late Supervising Engineer, Irrigation Department, Cape Colony, "Irrigation in South Africa." The HON. SIR RICHARD SOLOMON, G.C.M.G., K.C.B., K.C.V.O., K.C., High Commissioner for the Union of South Africa, will preside.

MARCH 26.—R. H. BARRAUT, Resident at Jesselton, "British North Borneo."

MAY 7.—ALAN BURGOYNE, M.P., "Colonial Vine Culture."

MAY 21.—THE HON. J. G. JENKINS, "Australian Railways."

CANTOR LECTURES.

Monday evenings, at 8 o'clock :—

VAUGHAN CORNISH, D.Sc., F.G.S., F.C.S., "Ocean Waves, Sea-Beaches, and Sandbanks." Two Lectures.

Syllabus.

LECTURE I.—JANUARY 22.—The size and speed of ocean waves—The height of waves in lakes, seas, and rivers—The length of waves in lakes, seas, and rivers—The steepness of waves, and strains upon ships—The periodic time of waves, and the rolling of ships—The speed of waves and its relation to velocity of wind—The height of waves and its relation to velocity of wind—The time required to develop large waves, and the duration of storms—The length and speed of the swell observed after storms—The probable height of the swell during storms—The relation between the dimensions and path of a cyclonic depression and the nature of the winds produced—The depth in which waves break, and its relation to defence works.

LECTURE II.—JANUARY 29. — The action of waves and tidal currents on sea-beaches and sandbanks—The proper action of waves to drive sand and shingle shoreward—The proper action of waves to drive mud seaward—Special conditions under which the action on sand is reversed—The proper action of the tide to drive shingle in the direction of the flood—The normal removal of shingle from promontories and its accumulation in bays—The exceptional accumulation of shingle in salient positions, *e.g.*, at Dungeness—Groynes—The reason of the graded arrangement of shingle on the Chesil beach—The formation of a sandbank on the up-channel side of a promontory—Sandbanks in estuaries and their arrangement by tidal currents—Their rippled surface as a means of mapping these currents—Their influence on the formation of tidal bores—The struggle between land water and tidal water to arrange the sandbanks in the Severn—The variability of the Severn Bore as determined by these factors—The circumstances which determine the starting point of the Severn Bore.

LOUDON M. DOUGLAS, F.R.S.E., "The Meat Industry." Three Lectures.

February 5, 12, 19.

LUTHER HOOPER, "The Loom and Spindle: Past, Present, and Future." Three Lectures.

February 26, March 4, 11.

NOEL HEATON, B.Sc., F.C.S., "Materials and Methods of Decorative Painting." Three Lectures.

March 18, 25, April 1.

HOWARD LECTURES.

Monday evenings, at 8 o'clock :—

CAPTAIN H. R. SANKEY, R.E., M.Inst.C.E., "Heavy Oil Engines." Four Lectures.

April 29, May 6, 13, 20.

Dates to be hereafter announced :—

F. MARTIN DUNCAN, "The Work of the Marine Biological Association."

JOHN NISBET, D.Oec., late Conservator of Forests, Burma, "The World's Decreasing Timber Supplies."

CHARLES C. ALLOM, "The Development of Artistic Skill in the Applied Arts."

ERNEST KILBURN SCOTT, Assoc.M.Inst.C.E., M.I.E.E., "The Manufacture of Nitrates from the Atmosphere."

CHARLES BRIGHT, F.R.S.E., M.Inst.C.E., M.I.E.E., "The Administration of Imperial Telegraphs."

HAROLD COX, "The Interdependence of Morals and Economics."

E. D. MOREL, "British Rule in Nigeria."

GORDON CRAIG, "Art of the Theatre." MISS ELLEN TERRY will preside.

THEODORE E. SALVESEN, "The Whaling Industry of To-day."

PROFESSOR ERNEST A. GARDNER, M.A., "Greek Sculpture."

GEORGE FLETCHER, "Technical Education in Ireland."

Hosted by Google

MEETINGS FOR THE ENSUING WEEK.

MONDAY, JANUARY 15...Bibliographical, 20, Hanover-square, W., 5 p.m. Annual Meeting. Presidential Address by Mr. H. B. Wheatley.

Brewing, Institute of (London Section), Criterion Restaurant, Piccadilly, W., 8 p.m. Mr. H. E. Field, "Fire Protection at a London Brewery."

Economics, London School of, Clare Market, W.C., 8.30 p.m. Sir Clement Kinloch-Cooke, "Emigration."

Surveyors, 12, Great George-street, S.W., 7 p.m. (Junior Meeting.) Mr. E. H. Blake, "Mortgages."

Geographical, Burlington-gardens, W., 8.30 p.m. Mr. Archibald Rose, "The Chinese Frontier of India."

London Institution, Finsbury-circus, E.C., 5 p.m. Mr. M. M. Pattison Muir, "Alchemy."

Architectural Association, 18, Tufton-street, S.W., 7.30 p.m. Mr. E. F. Strange, "Alfred Stevens."

TUESDAY, JANUARY 16...Statistical, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5 p.m. Professor S. J. Chapman and Mr. F. J. Marquis, "The Recruiting of the Employing Classes from the Ranks of the Operatives in the Cotton Industry."

Illuminating Engineering Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. T. E. Ritchie, "Colour Discrimination by Artificial Light."

Royal Institution, Albemarle-street, W., 3 p.m. Professor W. Bateson, "The Study of Genetics." (Lecture I.)

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Discussion on Papers: 1. Mr. S. H. Ellis, "Reinforced-Concrete Wharves and Warehouses at Lower Pootung, Shanghai." 2. Mr. W. C. Popplewell, "The Direct Experimental Determination of the Stresses in the Steel and in the Concrete of Reinforced-Concrete Columns." 3. Mr. W. H. Burr, "Composite Columns of Concrete and Steel."

Photographic, 35, Russell-square, W.C., 8 p.m. Mr. J. W. Gordon, "A Speculum Condenser."

WEDNESDAY, JANUARY 17...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. Cyril Davenport, "Illuminated Manuscripts."

Biblical Archæology, 37, Great Russell-street, W.C., 4.30 p.m. Anniversary.

Meteorological, 25, Great George-street, S.W., 7.30 p.m. 1. Annual Meeting. 2. Presentation of the Symons' Gold Medal to Professor Cleveland Abbe. 3. Address by Dr. H. N. Dickson (President), on "Some Meteorological Observations."

Metals, Institute of, at the Institution of Mechanical Engineers, Storey's-gate, S.W., 10.30 a.m. 1. Professor Dr. C. A. F. Benedicks, "A Metallographic Hygroscope." 2. Dr. G. D. Bengough, "A Study of the Properties of Alloys at High Temperatures." 3. Professor H. C. H. Carpenter, "Further Experiments on the Inversion at 470° C. in Copper-Zinc Alloys." 4. Mr. R. H. Greaves, "The Influence of Oxygen on Copper containing Arsenic or Antimony." 5. Mr. F. Johnson, "The Influence of Tin and Lead on the Micro-structure of Brass." 6. Mr. Arnold Philip, "A Contribution to the History of Corrosion: the Corrosion of Condenser Tubes by Contact with Electro-Negative Substances." 7. Dr. W. Rosenhain, "The Nomenclature of Alloys." 8. Professor T. Turner, "The Behaviour of Certain Alloys when Heated in Vacuo."

Microscopical, 20, Hanover-square, W., 8 p.m. Address by the President, on "Certain Blood Parasites."

United Service Institution, Whitehall, S.W., 4 p.m. Earl Fortescue, "The Immediate Requirements of the Territorial Force, with special reference to Recruiting."

Royal Society of Literature, 20, Hanover-square, W., 5.15 p.m. Professor W. L. Courtney, "Dramatic Literature."

THURSDAY, JANUARY 18...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Indian Section.) Rev. Walter K. Firminger, "The Old District Records of Bengal" (to be read by the Rev. J. A. V. Magee).

Geographical, Burlington-gardens, W., 5 p.m. (Research Meeting.) Dr. J. S. Owens, "The Settlement of Sediment in Running Water."

Royal, Burlington House, W., 4 30 p.m.

Antiquaries, Burlington House, W., 8.30 p.m.

Linnean, Burlington House, W., 8 p.m. Dr. A. Anstruther Lawson, "Some Features of the Marine Flora of St. Andrews."

Chemical, Burlington House, W., 8.30 p.m. 1. Messrs. C. T. Heycock and F. E. E. Lamplough, "Boiling Points of Mercury, Cadmium, Zinc, Potassium and Sodium." 2. Mr. J. F. Thorpe, "Formation and Reactions of Imino-compounds. Part XVII.—The Alkylation of Imino-Compounds." 3. Messrs. W. H. Perkin, W. M. Roberts and R. Robinson, "1:2-Diketohydrindene." 4. Messrs. E. G. Jones, W. H. Perkin and R. Robinson, "Isonarcotine." 5. Mr. J. J. Sudborough and Miss M. K. Turner, "Esterification Constants of some Substituted Acetic and Benzoic Acids." 6. Mr. P. May, "Aromatic Antimony Compounds. Part III.—Primary Aryl Derivatives."

China Society, Caxton Hall, Westminster, S.W., 8.30 p.m. Staff-Surgeon W. P. Yetts, "Symbolism in Chinese Art."

London Institution, Finsbury-circus, E.C., 6 p.m. Rev. A. S. Palmer, "Literary Blunders."

Royal Institution, Albemarle-street, W., 3 p.m. Professor A. W. Bickerton, "The New Astronomy." (Lecture I.)

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Mr. C. E. Collins, "Holidays among Sea-Fowl."

Electrical Engineers, Victoria-embankment, W.C., 8 p.m. Discussion on Mr. A. H. Seabrook's paper, "Residence Tariffs."

Historical, 7, South-square, Gray's Inn, W.C., 5 p.m. Mr. H. Jenkinson, "The Records of the Royal African Company."

Mining and Metallurgy, at the Geological Society, Burlington House, W., 8 p.m. 1. Mr. F. Reed, "A Submerged Flexible-Joint Main." 2. Mr. C. Brackenbury, "Unwatering Tresavean Mine." 3. Mr. H. M. Morgans, "Notes on the Operation of Two Winding Engines." 4. Mr. C. P. C. Sullivan, "Stoping at the Calamon Mine."

Economics, London School of, Clare Market, W.C., 5 p.m. Dr. T. Farkas de Boldogfa, "The Constitutional Law of Hungary."

FRIDAY, JANUARY 19...Royal Institution, Albemarle-street, W., 9 p.m. Professor Sir James Dewar, "Heat Problems."

North-East Coast Institute of Engineers and Shipbuilders, Bolbec Hall, Newcastle-on-Tyne, 7.30 p.m.

Civil Engineers, 25, Great George-street, S.W., 8 p.m. (Students' Meeting.) Mr. G. Ingram, "The Turbo-Blower and Turbo-Compressor."

Engineers, Junior Institution of, at the Institution of Electrical Engineers, Victoria-embankment, W.C., 8.30 p.m. Sir George Greenhill, "The Sighting of Small Arms and Artillery."

Mechanical Engineers, Storey's-gate, Westminster, S.W., 8 p.m. Dr. Edward Hopkinson and Mr. Alan E. L. Chorlton, "The Evolution and Present Development of the Turbine-Pump."

SATURDAY, JANUARY 20...Royal Institution, Albemarle-street, W., 3 p.m. Rev. John Roscoe, "The Banyoro; a Pastoral People of Uganda. I.—The Milk Customs."

Hosted by Google

Journal of the Royal Society of Arts.

No. 3,087. VOL. LX.

FRIDAY, JANUARY 19, 1912.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, JANUARY 22nd, 8 p.m. (Cantor Lecture.) VAUGHAN CORNISH, D.Sc., F.G.S., F.C.S., "Ocean Waves, Sea-Beaches, and Sandbanks." (Lecture I.)

WEDNESDAY, JANUARY 24th, 8 p.m. (Ordinary Meeting.) WILLIAM J. GEE, "A New Process for Hydraulic Separating and Grading." ROBERT KAYE GRAY, M.Inst.C.E., will preside.

Further details of the Society's meetings will be found at the end of this number.

INDIAN SECTION.

Thursday afternoon, January 18th; SIR KRISHNA GOVINDA GUPTA, K.C.S.I., in the chair. A paper on "The Old District Records of Bengal," by the REV. WALTER K. FIRMINGER, B.D., Senior Chaplain, H.M.'s Bengal Establishment, was read by the REV. J. A. V. MAGEE, M.A.

The paper and discussion will be published in a subsequent number of the *Journal.*

THE ROYAL SOCIETY OF ARTS.*

By SIR HENRY TRUEMAN WOOD, M.A.,
Secretary of the Society.

VI.—THE PREMIUMS.
(1754–1851.)

Continued.

In the first twenty years or so of its existence, down to 1776, the Society expended a little over £1,500 in premiums connected with the manufacture of textiles—part in establishing, or attempting to establish, new branches of the industry, part in endeavouring to improve textile machinery. With regard to the latter part of the work, it is easy to see, after a century's experience, that they were working on wrong lines; but that is merely to say that the members of the Society who directed its proceedings were no wiser (or not much wiser) than their contemporaries. They took immense pains to improve existing apparatus, instead of—as if they had been gifted with sufficient prophetic insight they might have done—anticipating the slow course of inventive progress, by encouraging the production of new methods. It is reasonable to wish they had been more enterprising; it is unreasonable to blame them for their lack of non-existent knowledge. *Ex post facto* criticism of the sort is as foolish as it is easy.

The Society's treatment of the important question of spinning mechanism is a good case in point, and it is very clearly stated by Dossie.* At the time when he was writing (1768) a certain amount of progress had been made in the construction of spinning machinery. Just thirty years before (1738) Paul and Wyatt's machine for "spinning by rollers" had been patented, and soon after the patent was granted the apparatus was in successful operation.† Yet Dossie, with full knowledge of the facts, gives his deliberate and reasoned opinion in favour of improving the ordinary spinning-wheel.

"I am authorised," he says, "to give this judgment on the principle of spinning by mechanism instead of the hand, from my own observations, as well as those of two other very judicious members of the Society, who were best acquainted with that matter, in the spinning machine invented by the late Mr. Paul, which carried this application of mechanics to the greatest extent it is perhaps capable of. By a very great expence, and the assistance of the most ingenious theoretic, as well as practical, mechanicians of our time, he attained to the construction of a machine, that being moved by

water, horses, or any other power, would spin, in the most perfect manner, any number of threads, without other assistance of the hand, than to supply the carded cotton, take away the finished roll of thread, and rectify any accidental disorders of the operation. But the delicacy of the work of the machine, equal almost to that of clocks, which subjected it to be easily disordered, and at the same time so expensive to be repaired, and the peculiar manner of carding, which was likewise very expensive, have occasioned this machine to be wholly laid aside as unprofitable, after sixty or seventy thousand pounds have been spent in various attempts to establish its use."

Now these remarks are perfectly sensible, and it was in consequence of the ideas and opinions that they embody that the attention of the Society was devoted to the improvement of the spinning-wheel. Various prizes were offered, and certain small improvements were duly rewarded. None of them, however, were of any great value, and, as we fully recognise now, the efforts of the Society were quite futile, and its energy was entirely misdirected. Hargreaves had already (1764) invented his "Jenny," and Arkwright had patented (1769) his "water-frame," while a little later (1780 or thereabouts) Crompton brought out his "mule." One wishes that those three names were to be found in the Society's lists, instead of three of the improvers of the venerable spinning-wheel, who were duly rewarded.

A good many rewards for improvements in the loom were made at different times by the Society.* In 1764 a prize of £100 was offered for improvements in the stocking-frame, and in the minutes of 1765 is an interesting description of the competition, for which a large number of persons entered. These were set up in the "machine-room," and a number of expert workmen were employed to test them. After a careful examination, the full prize was awarded to one of them, and this was supplemented by an amount subscribed by a number of manufacturers. This encouragement to British stocking weavers was of special value, because the manufacture was in a depressed condition at the time, and suffering severely from competition with the better productions of French looms.

The premium lists contain mention of occasional awards down to the year 1830, and amongst these were some for improvements of considerable value. Porter, writing in 1831,* refers to the improvements in silk weaving which had been rewarded by the Society, which he says, "has done more for the encouragement of ingenious artisans in this branch of industry than has been, or than could be, effected by the patent laws under the present system." Amongst these may be noted the improvements in the "drawboy" for which a prize was awarded in 1807 to A. Duff. The mechanical drawboy was invented by Joseph Mason, to whom, in 1687, a patent was granted for "weaveing such stuffes as the greatest trade in Norwich now doth depend upon, without the helpe of a draught-boy." Before his invention the cords of the loom, which had to be drawn in a prearranged succession in order to produce the pattern, had to be pulled down by a boy who stood at the side of the loom and used a large fork and lever for the purpose. When a mechanical device was substituted for the boy who acted as the weaver's assistant, the apparatus took its name from the original worker whom it replaced.

The actual invention of the drawboy has erroneously been attributed to Duff, but what he did was to introduce very considerable improvements. He himself, in his paper in the *Transactions*, disclaims novelty for his invention, which he describes as an improvement on methods previously known. Three years later, in 1810, J. Sholl was rewarded for further improvements on Duff's apparatus.† A little later still came the great invention of Jacquard, on which various improvements in details were made by English inventors. Some of these were rewarded by the Society, the most important of these being the invention of W. Jennings, a weaver or loom-maker of Bethnal Green, who reduced the great height of the Jacquard apparatus, and thereby rendered it available for use in the rooms in which the silk weavers then generally worked.‡

The manufacture of silk in England had been firmly established by the two great immigrations of Flemish weavers in the sixteenth century and of Huguenots in the seventeenth. Mills for "throwing" silk had also been set up in the eighteenth century. But the various attempts which had been made to produce silk in this country had all failed. The success of

* A very full account of the Society's relations with John Kay, the inventor of the fly-shuttle, was given in the *Journal* of December 8th, 1911, so there is no need to refer to them in the present article.

Hosted by Google

Louis XIV.'s great minister, Colbert, in establishing the production of silk in France aroused emulation over here, but without practical result. James I., whose efforts to encourage English manufactures perhaps deserve more credit than they have received, tried to acclimatise the silkworm, and for this purpose he had mulberry trees planted in St. James's Park on the site of the present Buckingham Palace. The experiment was continued for some time, since it is recorded that in 1628, Charles I. appointed Lord Aston keeper of "His Majesty's mulberry garden at St. James's, and of the silkworms and houses thereunto appertaining"; but the garden, as far as its original object was concerned, proved a failure, and turned into a place of public entertainment. A scheme started in 1718 had no better success. Large plantations were laid out in Chelsea, but after a short trial, the project collapsed. Dossie, in two letters which he wrote (under the signature of "Agricola") to the *Museum Rusticum* in 1766,* relates how a person, whose name is not given, sent some specimens of English-grown silk to the Society in that year, and how the Society, not considering his silk deserving any serious reward, yet encouraged him by the gift of a reel and basin such as were used by the silk-growers of Piedmont.† This seems to have been one of several attempts to grow silk in this country at the time, for some small prizes were awarded in 1763 and in 1778 for raising and winding silk. The Society seems to have held the view that the production of silk in England was not practicable, and while it took a good deal of trouble to promote silk-growing in the American colonies, it did nothing at first to encourage it in Great Britain. The specimens, however, abovementioned drew fresh attention to the matter, and Dossie rather vigorously combated the received opinion, urging that further experiments should be made. Accordingly, in 1768, a prize for English-raised silk was offered, and from time to time after this date, efforts were made to encourage the planting of mulberry trees and the raising of silk-worms. The Hon. Daines Barrington contributed a paper to the second volume of the *Transactions* on the subject, and in it he also urged the advantage of silk-growing in England, and gave some information as to the practice in the East and on the Continent. The Society continued to offer rewards for the plantation of mulberry trees, and for the production of silk, with the result that from time to time small quantities of cocoons were produced, but the matter never got beyond the experimental stage, where indeed it now remains. Some years later, in 1825, a vigorous attempt was made to raise silk here on a commercial scale, and a company with a large capital was started. It, however, was unsuccessful, and though even later proposals have been put forward for the plantation of mulberry trees and the raising of silkworms, they have never led to any practical result. In 1840, W. Felkin, of Nottingham, sent the Society some samples of British-grown silk, and was formally thanked for them, and in 1873 Sir Daniel Cooper produced some similar experimental specimens. The latest communication on the subject to the Society is a paper read in 1877 by Mr. Francis Cobb, in which the writer recommended the raising in England of silkworm "grain," or eggs, for exportation abroad. The reason generally put forward for the failure has been the lack of cheap labour, but whatever the cause, the fact remains that while it has been shown that perfectly good silk can be produced in this country, nobody has ever succeeded in producing it in profitable quantities.

At various times attempts were made to encourage the production of lace in England. The first award was taken in 1762 by Dorothy Holt, who made the ruffles worn by George III. at his coronation. Several other small prizes were given about the same time, but the matter dropped, and though some years later the offer of prizes was renewed, nothing very much came of it. Lace making was one of the very few domestic industries which survived, and perhaps it neither needed nor profited by artificial stimulation.

Between the years 1861 and 1865 the amount of £410 was expended in rewards for what was known as "quilting in the loom," that is to say, weaving fabrics having a diagonal pattern like a quilt. Such fabrics were imported from the East, and "Indian quilting" was much admired, as appears from occasional references in contemporary literature. Some, perhaps all, of the material was hand-made. It was not, however, produced in England, till the Society, in 1761, offered a prize for "a quantity of quilting, made in a loom in imitation of, and nearest in goodness to, the Marseilles or India quilting." In successive years samples of a gradually

* *Museum Rusticum*, Vol. VI. pp. 89 and 241.

† It appears from the minutes that the correspondent wrote under an assumed name, "Rusticus," but it seems, from a note by Dr. Templeman on one of his letters, that he was really John Delamare, a member of the Society and a silk manufacturer of Spitalfields.

Hosted by Google

improving character were produced in silk, cotton, linen and wool, until in 1765 the committee on Manufactures reported that "the manufacture appears to be sufficiently established," and the prizes were discontinued.

The writer of the "Observations on the Effects of Rewards" in the class of manufactures, appended to the list of awards published in 1778, writes in a very jubilant strain about the result of these particular prizes, for he says:—

"The manufacture is now so thoroughly established and so extensive, being wrought in all the different materials of Linen, Woollen, Cotton and Silk, that there are few persons of any rank, condition or sex in the kingdom (and we may add within the extent of British commerce, so greatly is it exported), who do not use it in some part of their clothing; so that we may safely say, if the whole fund and revenue of the Society had been given to obtain this one article of trade, the national gain in return should be considered as very cheaply purchased."

In the first half of the eighteenth century a number of factories had been started in England by Walloon, Flemish and French weavers for the manufacture of tapestry and pile carpets, apparently with but moderate success.* The subject was one to which a good deal of attention was paid by the Society, and premiums were given in 1757 to Moore, of Chiswell Street, and to Whitty, of Axminster, in 1758 to Passavent, of Exeter, and in 1759 to Jeffer, of Frome. It seems probable that Passavent's factory was the one founded about three years earlier, and mentioned by Johnson's friend, Baretti, two years later (1760).

By these awards, it is stated,† the manufacture of carpets "is now established in different parts of the kingdom and brought to a degree of elegance and beauty which the Turkey carpets never attained."

The drugget, for the manufacture of which a prize was offered in 1758, was not the floorcloth now known by that name, but a "sort of stuff very thin and narrow, usually all wool and sometimes half-wool and half-silk." ‡ It was used as a material for clothing, and as late as 1832 Bulwer Lytton describes one of the characters in his "Eugene Aram" as wearing a "spencer of light brown drugget." There was a great demand for it in the Lisbon market, and this market was mainly supplied from France, so it was thought that there was a good opening for British trade. Various awards were made during the next four years, and satisfactory samples were produced, but "owing to exterior circumstances attending the course of our trade with Portugal," the importation to Lisbon was never established. Dossie, who reports the matter, comforts himself with the philosophical reflection that if such a branch of the woollen manufacture had been established it would only have come into competition with branches already existing.

In 1809 the Society made the following award:—

"To the Patrons and Committee of the Flag Association, for a matchless specimen of double brocade-weaving in a flag now executing in Spital-fields, the silver medal set in a broad gold border."

A full account of this flag is given in a curious and rather interesting pamphlet which has been preserved in the Guildhall Library.*

It appears that Sholl and some other journeymen weavers formed a committee to produce some work which would afford proof of the capacity of British workmen to manufacture something as good as any foreign work. With this object they collected subscriptions to defray the cost of weaving a very elaborate flag. They collected over £570, but when the flag was finished they found themselves in debt for £380 more. The flag was exhibited at the Society's distribution of prizes in 1811, when the medal was presented, the flag being then finished. It seems by the description to have been a very remarkable piece of work, and from the terms of the award it was evidently highly approved by the committee. Its after history is not known, Sholl's work having been published in 1811.

About the end of the eighteenth century the idea of making fishing-nets by machinery seems to have attracted some attention both in France and in England. The Société pour l'Encouragement de l'Industrie Nationale (founded in 1801) offered a prize of 10,000 francs, a part of which (according to the "Encyclopædia Britannica") was awarded to Jacquard. In 1771 the Society of Arts offered a prize of twenty guineas for a similar object. Awards were made in 1776, 1796, and 1806, and the two machines (by Boswell, of Barnstaple, and Robertson, of Edinburgh), for

* A good summary account of these is given in the latest (eleventh) edition of the "Encyclopædia Britannica," in the article on carpets by Mr. Alan Cole. The history in the earlier editions is neither full nor accurate.

which the last two awards were made, look from the descriptions as if they would have worked well enough, but the above quoted authority states that the first efficient machine was by Paterson, of Musselburgh (the date of which was about 1820). The devices of some of these net-making machines were afterwards embodied in some of the later lace-making machines.*

What is now termed "Industrial Hygiene" was amongst the first subjects to which attention was given—that is to say, methods of preventing injury to workmen engaged in dangerous or unhealthy occupations, or proposals for the substitution of innocuous substances for those in the preparation or use of which there was risk of injury to life or health.

The late Mr. Benjamin Shaw, therefore, when in 1876 he founded a prize for inventions devised to minimise the risks incidental to industrial occupations, was only carrying out a very old tradition of the Society.

The first prize of the sort was offered in 1771, for any means of lessening the injurious effects of the process of fire-gilding or water-gilding, as it was sometimes called. In this process a coating of an amalgam of gold and mercury is applied to the metallic surface to be gilt. The mercury is volatilised by heat, and the gold is left as a thin adherent film. The process has now been to a large extent superseded by electro-plating; but it is still used for fine work, as it gives a very good solid deposit. The mercurial vapours given off are, however, extremely injurious to the operator, and before proper appliances were devised to carry them away, the early workers suffered severely from them. The offer produced an apparatus intended to remedy the objections, and in 1774 a prize of twenty guineas was awarded to its inventor (J. Hills), who kept a curiosity shop in Berwick Street. According to the description of Dossie † who (like the present writer) found Hills's own description unintelligible, the apparatus consisted of a funnel fixed in front of the furnace and over the article under treatment. This funnel was connected by a pipe to the furnace chimney, and a draught produced by a bellows drew up the fumes and discharged them into the flue. If necessary, glass screens could be added, with openings through which the workman could pass his hands, enclosed in leather gauntlets. After inspecting a model, the Society's committee ordered a full-sized apparatus to be constructed and set up. A "Mr. Platts, a workman in the water-gilding way," was engaged to work it. "A day being fixed, several members of the Society went to see its effect, and reported that they had not felt any of the so-called sweet vapour during the operation." Having thus assured themselves, by personal immunity from mercury poisoning, of the value of the apparatus, they decided to award Mr. Hills the offered prize. A little later Platts wrote that he had made use of the apparatus "ever since the trial." He added, "I ... wish I had been so happy as to have had the use of such an invention twenty years ago; I make no doubt but that I should have been free from the disorder I have so long laboured under."

The actual process of fire-gilding is practically identical now with that seen by the Society's committee in 1774, and a certain amount of risk is still run by the workman. But he works under very much better sanitary conditions, and he has the advantage of various appliances, such as india-rubber gloves, unknown to his predecessors of a hundred and fifty years ago.

Forty years later we find the same grievances existing, and a fresh attempt made to remedy them. In 1811 a prize of twenty guineas was awarded to Richard Bridgen for "a method to prevent the inhalation of noxious vapours in gilding metals." This time it was a mask to be fitted over the workman's nose and mouth, and connected to a tube, which was led to the back of the head, so that the air breathed was not charged with the fumes immediately proceeding from the heated metal. If preferred, the tube might be lengthened and led to a window, so as to provide communication with the external air. That the device was quite practical and effective, though decidedly inconvenient, may be admitted as certain. That it is still regarded in some quarters as a novelty is shown by the fact that when, eight years ago, in 1903, a special prize was offered by the Society for a dust-arresting respirator, several masks, identical in principle with Bridgen's, were submitted in competition.

A considerable further advance was made by John Roberts, who, in 1825, received a silver medal and fifty guineas for "apparatus to enable persons to breathe in thick smoke, or in air loaded with suffocating vapours." This apparatus would appear to be the original of the various modern devices, firemen's helmets, respirators and the like, used—or proposed—for enabling persons to breathe in smoke or noxious atmospheres. It consisted of a leather

† Dossie, Vol. III. p. 370.

Hosted by Google

helmet, padded so as to fit airtight to the wearer's neck and shoulders, and fitted with glass or mica eye-pieces. From the front of the helmet was suspended a flexible leather tube, with a helical wire inside, and terminating in a trumpet-shaped mouth. The object of this was to draw the air for respiration from near the floor level, where there was less smoke. The trumpet was filled with moist sponge covered with coarse cloth. For convenience, the pipe was strapped to the wearer's thigh. If the cloth was sufficiently porous, this must have been a very efficient and practical appliance. It is evident that the pipe was an unnecessary detail, and might have been dispensed with. Roberts's apparatus was carefully tested by the Society's committee, and was found to work very well, according to the account given in the *Transactions.** He himself was a working collier of St. Helens.

Considerable public attention was drawn a little later still (in 1830) to the Chevalier Aldini's† wire-gauze mask ‡ or screen for the use of firemen, and the Society gave him a gold medal, with the remark: "Something is still wanting to give to his ingenuity all the practical utility of which it is capable; and it is in the hope of this being effected that the Society again call to it the public attention." §

The dangers to health from many dusty trades, in which the harm is done by mechanical particles breathed by the workman, was not overlooked, and in 1805 a gold medal was offered for "obviating the prejudicial effects that attend the operation of pointing needles by grinding them dry, during which the particles of grindstone dust and steel, being thrown into the air, and received with it into the lungs, occasion asthma, consumption, and other painful disorders." The offer was afterwards extended to include other processes of dry grinding, and was continued for twenty years. In ordinary grinding work with a wet stone, the stone cuts more quickly, because the water washes away the metallic particles and fine dust, so that the grain of the stone is not, as the grinders say, "choked," but the dry stone, though it cuts more slowly, leaves a finer surface, and therefore has always been used for needle-pointing and for similar work.*

Of the various appliances submitted, some of which received rewards, the best was that of J. H. Abraham, of Sheffield, to whom, in 1822, the Society awarded its gold medal for a magnetic guard to protect persons employed in dry grinding. The apparatus is described in the *Transactions.*† The stone is enclosed in a wooden casing, so that only a portion is exposed, and the current of air generated by its revolution carries the dust into a tube, by which it is led away. The invention also includes a respirator to cover the mouth and nose. This respirator was fitted with magnets, for the purpose of arresting the fine particles of steel thrown off in the process of pointing needles, and in other processes of dry grinding. Although the invention was greatly appreciated at the time, and was actually brought into practical use, it never became popular, the main objection to it having been raised by the workpeople themselves, who feared that the lessened risk attached to their employment would lower their wages. Similar considerations have always stood in the way of the introduction of various appliances intended to limit the risks associated with all trades in which the workpeople breathe a dusty atmosphere.

The question of producing a lead glaze for pottery, which would be effective without affecting the health of those employed in the manufacture, is a very old and a very important one, and one that has not yet been solved. At a very early date it came before the Society, and in 1793 a prize of a gold medal was offered for "glazing earthenware without lead."

As is well known, the glaze on earthenware is merely a thin coating of glass, or silicate of soda. On many of the coarser forms of pottery, the glaze may consist of pure silicate of soda, and may be obtained by the use of common salt. But such a glaze is only applicable to clay bodies, which will stand a very high temperature—a class which includes a very large number of the roughest sorts of pottery, and also what is known as stoneware. By the use of lead a very much more fusible glaze is obtained, and this is available for all the more delicate kinds of porcelain and other more easily fusible ware.

The offer, in 1793, induced an application from one Law, who submitted specimens of an "East Indian material called by him 'She Kaw.'"

* *Transactions*, Vol. XLIII. p. 25.

† Giovanni Aldini (1762-1834) was an Italian physicist of some distinction, and Professor of Physics at Bologna.

‡ In 1827 a reward of five guineas had been paid to J. Callaghan for a wire-gauze "face-guard for smelters." This was intended merely to protect the face from heat, but it might have been applied to other purposes. (*Transactions*, Vol. XLV. p. 152.)

Samples were submitted to Thomas Wedgwood for report, and he reported adversely on the material, which proved to be some sort of selenite.

For many years the offer was continued without any result, until 1820, when a claim was made by John Rose, of Coalport. "The principal ingredient of my glaze," he wrote, "is felspar of a somewhat compact texture, and a pale flesh-red colour, which forms veins in a slaty rock adjoining to the town of Welsh Pool, in Montgomeryshire. This material, being freed from all adhering pieces of slate and of quartz, is ground to a fine powder, and being thus prepared, I mix with 27 parts of felspar, 18 of borax, 4 of Lynn sand, 3 of nitre, 3 of soda, and 3 of Cornwall china clay. This mixture is to be melted to a frit, and is then to be ground to a fine powder, 3 parts of calcined borax being added previously to the grinding." This was perhaps the first of the many felspathic glazes which have been suggested as substitutes for lead glaze. It was, no doubt, an excellent glaze, and probably well deserved the gold medal which was awarded to Mr. Rose for his invention. Two years later, in 1822, another premium was awarded to J. Meigh, of Shelton, Staffordshire, for another felspathic glaze.

The offer of the prize was continued for another two years, and in the meantime arsenic had been added to the prohibited ingredients. But after 1823 the premium was discontinued.

As is well known, the problem has not yet been satisfactorily solved. As late as 1910 a Departmental Committee reported on the dangers attendant on the use of lead in the manufacture of earthenware and china, and this report contains the fullest and latest information on the subject of leadless glazes. Many such glazes have been added to that of John Rose, but none of them are so effective as, and all of them are more expensive than, a glaze in which lead forms a part. Very great improvements have naturally been made in the manufacture, and to a very large extent the desired end has been attained by the method of preparing the lead glaze, which is now made of a much less soluble character than of old, so that the processes of manufacture are much less dangerous to the workmen. By such means, and by insisting upon proper sanitary precautions, the death-rate has been so largely reduced that practically the object sought for has been attained without the necessity for prohibiting methods of earthenware-making, which, whatever might be their result upon the health of the workers, would only, in the opinion of those best qualified to judge, have the result of driving the manufacture of high-class ware out of the country, and of placing it in the hands of foreigners.

Until quite the end of the eighteenth century, chimneys were always swept by climbing boys, and nobody seemed to see any hardship in this occupation for children. Even so kindly a soul as Charles Lamb, in his essay on chimney-sweeps, ignores the enormous amount of brutality and cruelty which fell to the lot of "those tender novices, blooming through their first nigritude." Mrs. Montague, the celebrated "blue-stocking," gave the climbing boys an annual dinner, and so, if Elia is to be believed, did his old school-fellow, James White. But the first to make a serious effort to improve their condition appears to have been Jonas Hanway, who was instrumental in introducing into Parliament the Bill which was passed in 1788. This Act (28 George III. c. 48) imposed certain restrictions on the business, but, on the whole, was ineffective.

In 1796 the Society offered a prize for an apparatus for "obviating the necessity of children being employed within flues." A note to this announcement refers to the great hardships endured by, and to the frequent fatal accidents occurring to, the children employed. The prize offered was a gold medal or forty guineas. This prize was renewed at intervals up to 1803. Various proposals were submitted, including a machine by G. M. Smart, but no awards were made before 1805, when Smart sent in an improved machine, and to this the prize was awarded. This apparatus was practically the same as that which is now used —namely, a number of rods connected together, and carrying a brush at the top. In Smart's apparatus the rods were hollow; they fitted one into the other by means of sockets or screws, and were all held together by a cord running through them. This machine was afterwards known as the "scandiscope," and soon came into general use.* According to a note in the *Transactions*, Smart had given up his own profitable business from philanthropic motives, and devoted himself to the invention and popularisation of chimney-sweeping apparatus.

* A great deal of information about the climbing-boys and the reform which led to their suppression will be found in Mayhew's "London Labour and the London Poor" (edition of 1861), Vol. II. p. 399. Howe, in his "Everyday Book," Vol. II. p. 518, also gives many curious and interesting details, including a quaint advertisement of the scandiscope.

Hosted by Google

In the year 1800 the Society for Improving the Condition of the Poor took up the subject, and in 1803 a special society was formed for superseding climbing-boys. The treasurer of this society at one time was William Tooke, a vice-president of the Society of Arts, who many years later, on the death of the Prince Consort in 1862, held the presidency of the Society for a year until the election of the then Prince of Wales (King Edward VII.). It was due to the exertions of Mr. Tooke, and to the appeal of Mr. J. J. Angerstein, the well-known philanthropist, that the Society of Arts associated itself with the newly-formed society, and renewed its offer of prizes for machines for sweeping chimneys. In 1817 a Parliamentary inquiry was held, at which Tooke, Smart, and others gave evidence, and this led to the passing of a second Act in 1834 (4 & 5 Will. IV. c. 35). Eventually a third Act (3 & 4 Vict. c. 85) was passed in 1840. This came into force in 1842, and at last put an end to the use of climbing-boys.

After the award to Smart various other prizes were given for other chimney-sweeping machines, including some in which the brush was dragged through the flues by means of a rope. But none of these seem to have come into use in this country, although the rope machine is extensively employed in France.

Considering that the foundations on which the science of chemistry was eventually built were only laid in the last years of the eighteenth century, it is obvious that such industries of a chemical nature as existed could only be of a purely empirical character, and were not really conducted on scientific principles at all. Some progress, it is true, had been made in technical chemistry abroad,* but in England there had been but little advance. Indeed, it was the discovery by Leblanc, in 1792, of the method of making carbonate of soda from common salt that really formed the basis of modern industrial chemistry, since it provided a cheap source of alkali, previously only obtainable from vegetable ashes as an impure carbonate of potash and soda, or in the form of salpetre (nitrate of potash), either native or artificial. In an early premium list (1770) is included a prize for barilla,† "made from Spanish kali, raised in Great Britain." The offer was continued for thirty years, but produced no results, nor was a similar offer for barilla grown in any British possession more effective, though the barilla industry was an important one in India, and Dr. Roxburgh, the great Indian botanist, who died in 1815, reported that one species of *Salicornia*, abundant on the Coromandel coast, might yield barilla sufficient to make soap and glass for the whole world. No better result was obtained by a similar prize offered for British grown kelp, richer in alkali than the ordinary sort.

Later on (1783) the true way of supplying the demand for alkali was suggested in the offer of a prize for obtaining soda from sea-salt, a problem which, after exercising the minds of many chemists and inventors (among the most notable of these was Roebuck, the friend of Watt and Priestley, who ruined himself in the attempt), was eventually solved by Leblanc, in response to a prize offered, not by the Society of Arts or any other society, but by the Emperor Napoleon.

The Society's efforts to increase the supplies of saltpetre or "fossil fixt alkali" have already been referred to in the article dealing with the Colonies.* An attempt was also made to establish works for the production of saltpetre in England, but the only result of these efforts was to demonstrate the impracticability of manufacturing it on a commercial scale at a price which would compete with that of imported saltpetre, and, after a few years, the attempt was abandoned.

Rewards were also offered for the production of borax, sal-ammoniac, bismuth, and some other materials in Great Britain, but naturally without more result. Somewhat better fortune attended an effort to establish in England the manufacture of verdigris (basic acetate of copper), used as a pigment and a dye, and then imported from France, where it was made by treating copper-plates with wine-lees.† In this country the necessary vegetable acid was obtained by using the pulp of apples from cider-presses, and other fruit-juice. By the offer of liberal and continued grants, the industry was actually started, and a considerable amount of the material was produced, but no regular manufacture was established.

One of the two first prizes offered by the Society was for English cobalt, the object being the production of smalt and zaffre, both silicates

* Sir Edward Thorpe, in his "History of Chemistry" (1909), gives the names of Gahn, Marggraf, Duhamel, Réaumur, Macquer, Kunkel and Hellot as the pioneer technical chemists of the eighteenth century.

† Barilla was the ash of plants of the genus *Salicornia* or glasswort. It contained only about a fourth of its weight of carbonate of soda.

* *Journal*, September 29th, 1911.

† The chief seat of the manufacture is still Montpellier, in France.

Hosted by Google

of cobalt, associated with silicate of potash, and made by melting the oxide of cobalt with sand and potassium carbonate. The glasses thus obtained form useful blue colouring matters. The first offer (1754) produced some samples, and an award of £50 was paid for cobalt from a Cornish mine in 1755. Nine years later, a similar sum was granted to Nicholas Crispe, the watchmaker, one of the founders of the Society, for making zaffre and smalt. Again, in 1810, the attempt was renewed, but without practical result.

Among the earliest objects to which attention was directed was the improvement of methods of dyeing textiles, wool, silk and cotton, and the encouragement of the domestic production of the materials (mainly vegetable) which were then employed. England was much behind other countries in its methods of dyeing and calico-printing (as it was in most other industrial processes) when the Society was founded, and much of the cloth woven here had to be sent abroad to be dyed, as much of the linen had to be sent abroad to be bleached. The very first prize offered by the Society was for a dyeing material, madder, and this was followed by others for dyeing cloth, silk, linen and cotton, sometimes of specified colours, and sometimes by improved or cheaper methods, or by materials not previously used. The Society worked hard for twenty years to establish the cultivation of madder in England, and by 1775 it had expended a sum of £1,516 in the effort. After the first two or three years, it paid a definite amount of £5 per acre of madder grown annually, and these payments varied from £5 for a single acre up to, in one exceptional case, £145. After 1775 the rewards were discontinued, the Society's object having so far been attained that the price of imported madder was reduced, and its quality improved, by the competition of the home-grown product. It is also recorded that the Society was instrumental in obtaining an Act of Parliament, which modified the amount of tithe levied on crops of so costly a nature as madder.*

Numerous rewards were offered for the importation of new or little known dye-stuffs from the colonies, and some rather unavailing efforts were made to start in England the growth of tinctorial plants more suited for other climates. Such, for instance, were the orchella weed (*Rocella tinctoria*), a lichen native to many parts of the world and producing the colouring matter archil, or orchil, long used for dyeing red and purple; and, even a less reasonable proposal, indigo. A premium for growing the former in Great Britain was offered in 1763, and a similar offer was published in 1817 with reference to indigo. A suggestion in 1763 as to the employment of Prussian blue (sesqui-ferrocyanide of iron) may be noted. The material was known at the time, but appears not to have been used as a dye.

Besides thus endeavouring to add to the list of materials available for the dyer, the Society included in its premium list the production of new or improved colouring matter for use as pigments. Amongst these perhaps the most important was a substitute for white lead. For over fifty years from 1788, when it was first offered, a prize for a "substance for the basis of paint" "equally proper for the purpose as the white lead now employed," appeared in the premium list. The value of the prize was at first £30, but it was afterwards raised to 100 guineas. That the prize was never awarded is not perhaps very remarkable, since it is only of quite recent years that even a partial substitute for white lead (a basic carbonate of lead) has been found in zinc-white (zinc oxide), and even this, though it is non-poisonous and is unaffected by atmospheric influences, does not combine with the oil of the paint as effectively as the lead, while the paint has less "covering power," and is more costly.

In the first printed list of premiums is a prize for improved varnish, and from time to time prizes were offered for varnishes, materials for varnish-making, methods of bleaching lac, etc. Although some small rewards were given, the offers appear to have had no practical result until 1833, when a gold medal was presented to J. Wilson Neil for a paper on the art of making copal and spirit varnishes. Until the publication of this memoir, varnish-making had always been professedly a trade secret, and the methods of its manufacture were jealously concealed. Mr. Neil, however, who was a varnish-maker of great experience and of considerable reputation, put an end to this state of things by giving full and copious details of all the methods and materials employed. His paper, which occupies fifty-five pages in Vol. XLIX. of the *Transactions* (1831-3), pp. 33–87, was for long the principal, if not the sole, source of information on the subject, and though its contents have often been republished, it remains to the present day a valuable treatise on the manufacture, and may still be consulted with advantage.

* Dossie, Vol. I. p. 42.

At a time when oil was the chief source of illumination, and vegetable oils were scarce and expensive, many attempts were made to get rid of the fœtid smell of the train oil which was for many purposes, on account of its cheapness, the only sort available. A very early prize was offered by the Society (in 1757) for the "edulcoration" of oil. According to Dossie,* the result can hardly be considered to have been satisfactory, for when samples of the "edulcorated" oil were compared with some of the same oil before treatment, "it was difficult to say which was the worst. For the operation had added an empyreumatic smell to the putrid fœtor which was very little diminished." Dossie, however, can hardly be considered an impartial critic, for he afterwards (1761) produced a process of his own, for which the Society gave him £100. His process consisted in treating the oil with chalk or lime, and adding either common salt or potash. It was said to have been very successful.†

A good example of the results of the efforts of the Society to introduce new medicinal plants is afforded by the introduction of rhubarb (*Rheum palmatum*) into Great Britain. In 1763, the Society appointed a Committee "to pursue the requisite measures for introducing the culture of the true rhubarb," and eventually a gold medal was offered.

The Committee obtained specimens of the plants and roots from various sources, but were doubtful if they had got hold of the genuine rhubarb, until they found that Dr. Mounsey, an English physician settled in Russia, had, at the suggestion of Sir Alexander Dick, President of the Royal College of Physicians of Edinburgh, sent over some seeds of the plant, which had been planted by various persons in England and Scotland. Dr. Hope, the Professor of Botany at Edinburgh, had raised some plants, others had been "raised in the garden of the Museum in London." Accordingly, in 1769, gold medals were awarded to Dr. Mounsey for introducing the seed, to James Inglish for raising plants from it,‡ and seven years later (1776) Sir A. Dick was awarded a gold medal, and Mr. Callendar, of Newcastle, a silver one. The Society still continued its rewards in order to secure the growth of the plant on a commercial scale, and during the following twenty years various medals were given, amongst others a silver medal, in 1789, and a gold one, in 1794, to William Hayward, of Banbury, which town became, and still remains, the principal seat of the industry in England.

* Vol. I. p. 188.

† Dossie's paper was published in full, some time after the author's death, in the *Transactions*, Vol. XX. (1802) p. 209.

‡ A full account of the history of the introduction of rhubarb is given in Dossie, Vol. II. p. 258, and in Vol. III. p. 208, there is a very interesting letter from Sir A. Dick.

Another medicinal plant, the growth of which it was attempted to encourage, was opium. In 1796, John Ball, of Williton, Somerset, sent to the Society some samples of home-grown opium, and, as on examination the drug proved to be of good character, a "bounty" of fifty guineas was presented to him. Full details of his method of growing the poppies and of obtaining the extract were supplied by Mr. Ball,* who wrote enthusiastically about the prospects of his crop, and said that he expected to be able to dispose of all that he could grow to a London druggist at the price which foreign opium then fetched, viz., twenty-two shillings a pound.

In the premium list for the following year, 1797, gold and silver medals were offered for specified amounts of British-grown opium, and this offer was continued for some time, though without much response. In 1800, the larger prize was awarded to Thomas Jones, who for some years had grown opium at Enfield and elsewhere.† Though he says he found more difficulties than Mr. Ball had reported, and had suffered in some years from unfavourable weather, he had produced considerable amounts of saleable opium, which was reported upon as equal to the best Turkey. It was concluded that the possibility of producing the drug commercially in England had been demonstrated.

After an interval of nearly twenty years, yet another gold medal was awarded, in 1819, to John Young, an Edinburgh surgeon, who had successfully grown opium in Scotland. He, like his two predecessors, contributed a very full and interesting paper to the *Transactions*,‡ and he writes as if he had had some experience of Indian opium-growing. He states that he had obtained 56 lbs. of opium from an acre of ground, which, at 36*s.* per pound (the London price at that time), would bring in a little over £100. The total net profits per acre are estimated at £110 7*s.* 6*d.* It was therefore demonstrated that opium, as rich in morphia as the eastern product, can be grown in Great Britain, but it is one of those crops which requires an abundance of cheap labour, and probably for that reason its cultivation has never been permanently established here.

In 1801 a gold medal was offered for the production of artificial ultramarine. The offer was continued for a good many years, and in the list for 1812 a note was added that "it appears from the analysis of lapis lazuli by Klaproth, and the experiments of Guyton (related in the 'Annales de Chemie'), that ultramarine is a blue sulphuret of iron, and that a blue substance much resembling it is constantly found amongst the scoriæ of blast furnaces where iron is reduced." Nobody was found, however, to act on the suggestion. Foreign chemists were more enterprising, for after Tassaer in 1814 observed the spontaneous formation of a blue compound in the soda furnaces at St. Gobain, the Société pour l'Encouragement offered a prize for an artificial ultramarine. Ultimately the problem was solved by Guimet and by Gmelin, the latter of whom was then at Tübingen, and an industry was started which still flourishes in Germany. The material is a silicate of alumina and iron, together with iron sulphide. The manufacture has never been established in this country.

In 1821, a gold medal was offered for a test for arsenic, and the offer was continued for six years without result. Fifteen years later, however, it produced a communication from James Marsh, the well-known chemist of Woolwich Arsenal, and to him the medal was awarded, in 1836, for the test since known by his name. Marsh's test for arsenic is described in all chemical text-books, and is familiar to all chemists. It is only necessary to say that the description given in the *Transactions** holds good to-day. The test is one of extraordinary delicacy, and the cautions given by the inventor as to the need for special care in securing the purity of the reagents employed are as necessary now as when they were written.

PROCEEDINGS OF THE SOCIETY.

SIXTH ORDINARY MEETING.

Wednesday, January 17th, 1912; Sir Walter Armstrong in the chair.

The following candidates were proposed for election as members of the Society:—

Aiyar, Palayam Rajam Sesha, B.A., 10, Kuppumuthu-street, Mount-road, Madras, India.

Baker, Asa George, Messrs. G. & C. Merriam Company, Springfield, Massachusetts, U.S.A.

Barbour, James Foster, Maysville, Kentucky, U.S.A.

Bowles, George Vernon, c/o Messrs. Read Brothers, Ltd., Kentish Town, N.W.

Butt-Gow, H. F. S., Laimakuri, Dibrugarh P.O., Upper Assam, India.

Crouch, Vernon Foster, J.P., c/o Chief Native Commissioner, Salisbury, South Rhodesia, South Africa.

Durrant, Hubert Arthur, Hunstanton, Norfolk.

Eberle, Professor Eugene G., Ph.G., A.M., Dallas, Texas, U.S.A.

Fuchs, Ernest, Box 334, Guadalajara, Mexico.

Gibbs, Eustace L., Tyntesfield, Flax Bourton, Somerset.

Harkness, William Young, Lago Vista, Negritos Payta, Peru, South America.

Hughes, Vivian Arthur Beesley, Ellerslie, Grassfield-avenue, The Cliff, Manchester.

Langton, John James Perez, 421, South Seventh-street, St. Louis, Missouri, U.S.A.

Leitner, Henry, The Leitner Electrical Company, 7, Prince's-street, Westminster, S.W.

Ripper, Charles, 7, Laurel Bank, Lancaster.

Scotland, Alexander Paterson, Keetmanshoop, German South-west Africa.

Sen, Diwan Mangal, Gujranwala, Punjab, India.

Spence, David, Ph.D., F.I.C., The Diamond Rubber Company, Akron, Ohio, U.S.A.

Windass, John, F.S.A.M., The Hall, Osbaldwick, York.

The following candidates were balloted for and duly elected members of the Society:—

Child, Henry William Robert, Briardale, 33, Crediton-road, West Hampstead, N.W.

Loch, Lieutenant Percy Gordon, I.A., c/o Messrs. Cox & Co., Hornby-road, Bombay, India.

Newlands, Lord, LL.D., 36, Grosvenor-square, W., and Mauldslie Castle, Carluke, N.B.

Prankerd, Miss Edith, 51, Campden Hill-court, Kensington, W.

The paper read was—

ILLUMINATED MANUSCRIPTS.

By Cyril Davenport, V.D., F.S.A.

Illuminated manuscripts form an important division of water-colour painting in a small or miniature size. The earliest existing manuscripts are Egyptian, and some of them are illuminated, or ornamented with pictures. Early Egyptian paintings on papyrus are done in water-colours mixed with white, known as body-colour, tempera, or gouache. The designs are outlined in black or red and filled in with flat washes of colours, all of which have proved permanent. The colours used are iron-red, copper-blue, and green (and later, lapis lazuli blue), yellow earth, ochre, lampblack, and

* Vol. LI. p. 67.

Hosted by Google

chalk or white clay. Some of the books of the dead—particularly the Papyrus of Ani, written about 1500 B.C.—show these interesting paintings to perfection.

Until about the second century B.C. papyrus remained the chief substance upon which writings were made, but at that time a scarcity of supply occurred, and Eumenes II., King of Pergamum, introduced vellum, prepared from calf-skin, as a substitute. Vellum quickly superseded the brittle fibre of the Nile reed, and became, as it still remains, the ideal material for writing and illumination.

From the fourth century onwards, until the sixteenth, we find an unbroken series of European illuminated manuscripts on vellum; and the illustrations found in these follow, in the main, after about the thirteenth century, the general characteristics of the art of their particular period and country.

The schools of illuminated manuscripts may be very roughly divided into two main divisions —the Byzantine and the Gothic—each of which may again be subdivided almost indefinitely.

In A.D. 330 the Emperor Constantine went to Byzantium, and the great early epoch of Christian art began shortly afterwards. It was, primarily, a religious movement, and in some sort a reaction against the classicalism of Rome. Oriental feeling is evident. Asia Minor, Syria, and Africa, all influenced Byzantine art. No doubt numbers of pre-Byzantine manuscripts existed, but they have almost all disappeared. There were great losses of libraries at Constantinople, Alexandria and Rome, and numbers were also destroyed by the Iconoclasts in the eighth century.

Byzantine manuscripts are written in Greek; the vellum is sometimes stained purple, and the early writing is in large letters of gold and silver. The style reached its highest point of excellence about the tenth and eleventh centuries, and its influences are still apparent in the ritual of the Greek Church and in Russian religious art generally. The effects are richly decorative and gorgeous in colour, the figures stately, with carefully arranged drapery and accessories. As authority for ceremonial, manners, costume and furniture, the value of illuminated manuscripts cannot be overstated.

So-called Byzantine influence was strong in European illuminated manuscripts until the twelfth or thirteenth centuries, when the work of each country began to differentiate according to the national influences brought to bear upon it. After this it becomes possible, with increasing certitude, to attribute a given piece of illumination to a definite country of origin. At the same time it must not be forgotten that, as the knowledge of minute peculiarities of style increases, many manuscripts that can at present only be classed as Byzantine, will probably be more definitely placed. Early manuscripts, so far as styles go, are indeed largely composite productions, and many influences have been brought to bear upon them.

Early Byzantine manuscripts commonly contain full-page miniatures, and the script is large, the letters often being uncials (*uncia*—an inch), or what we might call small capitals. Later manuscripts of the eleventh and twelfth centuries or thereabouts, are usually in small letters (minuscules), and show small miniatures in borders, headpieces and groups.

About the end of the twelfth century a remarkable change took place in the general style of production and ornamentation of manuscripts. Generally the books tended to become smaller (although until the fifteenth century large books were often made in Italy, France and Flanders), and the writing as well as the illuminations became more delicate. Much attention was now paid to the decoration and exemplification of initial letters, which began to be ornamentally extended upwards and downwards along the blank margins of the pages, and the full-page miniatures of the Byzantine period tended to disappear. The Gothic style may be said to have prevailed from the twelfth or thirteenth century until the fifteenth century, when, for the remainder of the time of production of illuminated manuscripts, it merged into Renaissance styles, particularly in Italy and Flanders. Gothic influence was most marked in the work done in England, France, and Flanders, where it caused a remarkable development, but in Italy it had only a slight influence. The periods of highest distinctive development of the art in Europe took place in the thirteenth and fourteenth centuries in England, in the thirteenth, fourteenth and fifteenth centuries in France, and during the fifteenth and sixteenth centuries in Italy and Flanders.

The classical Renaissance, which began in Italy about the middle of the fifteenth century, had some effect on Italian illuminations, and also on Flemish, but it came too near the period of the end of the art altogether to have a universal influence.

The art of illumination in Spain, Bohemia,

Hosted by Google

Hungary, and Poland never reached any distinctive eminence. The work done can only be considered as a variety of one or other of the well-known styles.

Ireland.

Now it is necessary to go back into the earlier period of the art of illumination in order to consider a most interesting and beautiful school of ornamentation that possesses rare peculiarities of its own. The Byzantine School was pictorial—the Celtic, which we are now considering, is ornamental. The ornamental ideas which are so exquisitely shown in Celtic manuscripts have undoubtedly had very great influence over the imaginations of designers of European manuscripts. Traces of this influence can be seen for a very long time in purely ornamental work. As well as "Celtic," this school may be called "Irish," "Anglo-Irish," or "Hiberno-Saxon." In any case the inspiration is certainly from Ireland, if not the actual execution. Irish scribes, celebrated in early times, migrated freely to the Continent, and their work was very highly esteemed. The chief examples of illuminated Celtic work now existing are:—

The Book of Durrow. At Dublin. Seventh century.

Dimma's Book. At Dublin. Seventh century.

The Lindisfarne Gospels. In the British Museum. Eighth century.

St. Chad's Gospels. At Lichfield. Eighth century.

The Book of Armagh. At Dublin. A.D. 807.

MacRegol's Gospels. At the Bodleian, Oxford. Ninth century.

The Book of Kells. At Dublin. Probably eighth or ninth century.

MacDurnan's Gospel Book. At Lambeth. Ninth or tenth century.

So that, although the actual dates of these Irish manuscripts are very uncertain, it is clear that, for about four hundred years, we know that Irish scribes and illuminators produced magnificent manuscripts, a few of which still exist. The ornamentation is the most remarkable point in these manuscripts. We find a bewildering mass of interlacing forms, human, lacertine, serpentine, quadrupeds and birds, then there are curves and spirals, plaited and knotted work, and tessellated designs in great profusion. These ornamental motives resemble contemporary work in bone, stone, metal and basketwork, and some may, I think, have been derived from woven work. Many of the three lobed ornaments, "triquetra," nearly resemble modern Japanese designs, and similar work to many of the curves and interlacings can be traced in Maori wood-carvings. The colours used are generally thick and opaque, probably mixed with glaire of egg as a medium. The most commonly used are light red or orange, green, blue, purple, pink, yellow. The designs, however involved, are measured out in a masterly way, and exquisitely drawn. The outlines are in black or brown. A few words here and there are written in powder gold, but I do not think leaf-gold has been originally used in any of these manuscripts. There are some parts of the Lindisfarne Gospels picked out with leaf-gold, but I believe these to have been added at some late period. The ornamental designs are often outlined with small red or orange dots.

England.

English work from the eighth to the twelfth centuries shows some Byzantine and Celtic feeling, combined with other influences. Anglo-Saxon work is of great interest, especially for the curious outlining, and the peculiar attitudes of the figures. In the tenth century there was a large output of beautiful work, mainly coming from Winchester, Westminster, St. Albans and Exeter. The framework or borderings of many of the full-page miniatures are often of great beauty. In the twelfth century the Gothic style began to assert itself, and the work generally tends to become smaller, and more delicate. The thirteenth and fourteenth centuries saw the same style continued, the Gothic influence affected English and French illuminators in the same way, so that the difference between them is often very difficult to detect. Initial letters become more and more ornamental, and the full-page miniatures tend to disappear. In the fourteenth century the highest point of excellence in English illumination may be said to have been reached. There are fine "bar" and "frame" borders, reminiscent of the beautiful Winchester work of an earlier time, and there are many instances of small grotesques and imaginative and fancy designs in borders and initial letters. "Queen Mary's Psalter" belongs to this period. On some of the fragments of a Bible made for Richard II. appears a remarkably beautiful tracery on gold-leaf backgrounds, a small decorative pattern traced out by means of pointillé work, a manner of working that for delicate charm is unequalled. The "Sherborne Missal," belonging to the Duke of Northumberland, is also a magnificent specimen of English work. The fifteenth century saw the decline and practically the end of the art of

Hosted by Google

the English illuminators, and later work of this kind done here was chiefly the work of foreign artists, mainly Netherlandish.

Although printed books have finally superseded illuminated manuscripts, except as luxuries, the capacity of English artists to produce the latter in a style that need fear no comparison at all is shown in the case of an exquisite little manuscript recently presented to the British Museum by Lady Burne-Jones. It is a copy of Fitzgerald's "Rubaiyat" of Omar Khayyam, translated, written and illuminated by William Morris in 1872, with figures painted by C. Fairfax Murray, from designs by William Morris and Sir E. Burne-Jones.

France.

In France, in the eighth and ninth centuries, occurred what is known as the "Carolingian Renaissance," due to a revived interest in art matters initiated and fostered by Charlemagne himself. In the main, this art was influenced by that of Rome and Ravenna, as well as that of Byzantium, and it also shows the influence of Moorish and Celtic art. Purple vellum and gold letters appear, but the work is coarsely executed. The great centres were Tours, Rheims, Metz and Aix-la-Chapelle.

In the thirteenth century in France the art of illumination generally began to throw off its Byzantine fetters, and with the advent of the Gothic wave of art, French artists readily fell in with the feeling of the new style, with which they quickly became identified, and in which they remained paramount until about the middle of the fifteenth century. Illuminated manuscripts became part of a recognised craft, and gradually ceased to be the monopoly of religious orders. Secular subjects were freely treated, and borders and accessories often show architectural motives. Minute lettering was much liked, and most delicately and beautifully executed. Besides Bibles and Psalters, numbers of herbals and bestiaries were made. Romances were produced in considerable numbers, and so were works on medicine and surgery: many of these show very interesting paintings of actual operations.

In the fourteenth century the great and varied output of French illuminators continued in an even increased degree, and most of the illuminated manuscripts made in other countries followed closely on French lines, which set an example to be followed all over Europe. Among the most distinctive smaller peculiarities found about this time in French illuminations may be noted fine diaper or tessellated backgrounds, the presence of a graceful running design of small gold ivy leaves, now and then in colour, and many illustrations showing figures in monotone or "grisaille."

During the fifteenth century the output of fine illuminations in France continued with vigour, beautiful work was done for the great collectors—the Duc de Berry, and John, Duke of Bedford. The illuminators whose names are best known, are Pol de Limbourg and Jehan Foucquet. Towards the end of the century came the decadence, and shortly after the advent of printed books the production of written manuscripts died out.

Italy.

In Italian illuminated manuscripts a similar course to the French may be observed, but the period of greatest excellence began a little later. We have seen that in France this period began in the fourteenth century, but in Italy it may be said to have begun about the fifteenth, and to have lasted into the sixteenth.

Before 1300 A.D., many Greek manuscripts were written in Italy. In early Italian illuminations curious rectangular nimbi were used to denote living personages. Celtic art shows its influence in many cases. The "Exultet" rolls made at Monte Cassino have the illustrations painted the reverse way to the script, so that a reader reading the roll and allowing it to drop over the desk before him, would show the pictures right way up to the audience.

The Gothic influences which so strongly influenced French and English work in the thirteenth and fourteenth centuries, had not so marked an effect upon Italian illuminations, which were, however, at that time at a period of comparative unimportance. Flesh colour shows a grey tinge with greenish shadows. Gilded studs or discs with filagree scrolls in pen-work often appear. At the period of the Renaissance, about the middle of the fifteenth century, the flowering period of Italian illumination began; now we find fine and brilliant work with distinctive and delicate designs and beautiful bright clear colour. The gilded discs still remain favourite, but a worthier peculiarity is found in the rich and decorative borders and patches ornamented with a design founded on a white interlacing spray of vine stalk with tendrils, often interspersed with animals, putti, masks, and other ornamentation at intervals. Beautiful books were made at Florence and Milan. The Sforza Book of Hours was made at Milan for Bona of Savoy about 1490, and Attavante degli Attavanti worked at Florence. In the sixteenth century

Hosted by Google

worked Giulio Clovio, a most clever miniaturist and very fond of shell gold. He was the last great Italian illuminator, and even his work shows the signs of decadence.

GERMANY.

On the decay of the Carolingian Renaissance in the ninth century—a renaissance which, to a considerable extent, affected German work, arose a more particularly German revival, known as the Ottonian Renaissance. In the tenth century Otto II. married the Byzantine Princess Theophano, and from Hildesheim, Richenau, Treves, and Ratisbon came many fine manuscripts in that and in the succeeding centuries. The work was coarse, with strong flesh tints. Large patterns are found with striped and interlaced backgrounds and hard technique. In the twelfth century there was a large output of big Bibles. German illuminations have always been more or less heavy and large.

FLANDERS.

Illumination in Flemish manuscripts began slowly to develop about the thirteenth century, and to differentiate in a similar way to that noticed in England and France. In the fourteenth century the production of illuminated manuscripts remained small; many Flemish miniaturists worked in France, and their work is difficult to distinguish from French work.

In the fifteenth century a greater activity shows, and the art attained a high level. Much distinctive work was done, delicate landscapes are plentiful, and many paintings in grisaille, often on monotone coloured grounds, are found. Excellent and typical work continued well into the sixteenth century, when most of the European countries had ceased their output. In the later period in Flemish work we find numerous examples of broad borders enclosing the script. These frame-like borders are rectangular and painted with flat monotone grounds, grey, pink, purple, and sometimes dull gold. On this groundwork are scattered flowers, fruits, birds, and insects delicately painted in natural colours, but with strong shadows, giving an appearance of high relief.

The latest glory of Flemish illuminated manuscripts is the "Grimani Breviary," now at Venice, executed about 1510. Some fine Flemish miniatures were added to the Sforza Book of Hours, painted in a like manner to the Italian work preceding them.

Like the other European schools of illuminated manuscripts, the Flemish, lasting longest, finally succumbed before the victorious march of the printing press.

Now that all these beautiful productions may be considered as examples of a no longer living art, we are able to consider them in a proper perspective, and as a whole. I feel sure that no one who has ever been privileged to examine the finest examples left of this exquisite art, whether in private hands or in public museums, can possibly fail to award the highest possible meed of praise and admiration to the mediæval monks, artists, illuminators, gilders, and scribes who produced them, many of whom were, undoubtedly, the best artists of their time.

DISCUSSION.

THE CHAIRMAN (Sir Walter Armstrong), in opening the discussion, said the difficulty in discussing the paper was to discover any point on which to differ from the author, and he therefore proposed, in the few remarks he desired to make, to amplify rather than criticise the excellent paper that had been read. Some of the earliest illustrations shown by the author dealt with Irish manuscripts. It always seemed to him that, in discussing Celtic ornament, especially the characteristic interlaced designs, sufficient stress had not been laid upon the fact that they were almost identical with the designs that were used by the metalworkers. In following a scroll or an elaborate interlacement through all its intricate ends, it was difficult to make it wrong in metalwork, and he thought the Irish must have learned their extreme accuracy in carrying out designs in illuminated manuscripts from the influence of their metalworkers. The Book of Kells was a perfectly marvellous piece of work from that point of view. He differed, however, from the author in thinking that the Book of Kells was the most beautiful Irish illuminated manuscript. It was far and away the most elaborate, but he thought, as a work of beauty and of artistic imagination, it was not to be compared with the Lindisfarne Gospels. So far as elaboration went it was a miracle, because it was possible to go through the most elaborate scrolls and interlacements and never lose hold of any of the threads. For instance, if the tail of one of the curious animals or snakes was found it was easily possible to find the head; in fact, the whole thing was a miracle of the virtues of extreme patience and contentment on the part of the workman, virtues that were getting rare in the present day. He also wished to mention the great vigour that was shown in the English illuminations down to the time when they lost their supremacy. As the author had stated, English illuminations were supreme down to some time in the fourteenth century; the end of their supremacy was generally put at about the time of the Black Death, in the middle of the fourteenth century. Up to that time they seemed to be characterised by more artistic vigour than any other illuminations, not only up to then but

Hosted by Google

since. There were a great many specimens in the British Museum which showed an extraordinary vivacity in the utilisation of dramatic motives. They were generally not the kind of illuminations which were the most attractive to reproduce, because they were mostly linear and not much in the way of colour, but they showed a vivacity and a power of dramatic design which he did not think reappeared at all in the art of illumination after that time.

MR. CECIL HALLETT said that, so far as he had observed, the effect of illuminated manuscripts upon the ordinary visitor to the British Museum was most disappointing. To his mind the manuscript room was one of the most interesting in the whole Museum; nevertheless, as he had experienced only that afternoon, it was the one part of the Museum in which he found it most difficult to interest an ordinary audience of visitors. He recently ventured to tell some visitors so as pleasantly as he could, suggesting at the same time that it was a kind of imputation upon our national character. All visitors seemed to be interested in the mummies but not in books, and he always dreaded the hour when it was his duty to show people the illustrated manuscripts and books. Of course, the trouble might be due to the fault of the guides. He desired to ask the author, in conclusion, how the Byzantine influence reached this country. Was it through the Norman Conquest?

MR. ROBERT STEELE was sure the audience would desire to express its extreme admiration for the enormous technical skill shown by the author in the production of the beautiful slides that had been shown. When it was remembered that the slides thrown on the screen, which appeared as pictures several feet high, were drawn and coloured by the author in the space of about an inch in length, those who had done any drawing would recognise the great skill that had been displayed. Turning to the subject of the lecture, the development of Celtic art had always seemed to him a most interesting chapter in the history of design. There was a main line of design in ornament which ran straight down from Greek times, through Rome, Italy and France, although not perhaps so much in manuscripts as in sculpture, and continuously down to the present day. This was an art of which almost nothing was known, but which one was led to suspect in Asia Minor, which ultimately produced Byzantine art, and through Byzantine art and its modification of Italian art had led to Romanesque and Gothic in its various ways. But in none of those arts was any affiliation found with the Celtic manuscrips. Skilled motives were discoverable in savage art right through the world. But in Mr. Herbert's book on manuscripts, a very magnificent book produced quite lately in the series under the author's charge, a hint was given which he thought solved the problem. In all other countries illuminated manuscripts passed from hand to hand; for instance, they were brought by the early missionaries from Rome to England; but as far as was known the missionaries who landed in Ireland were very poor men, with very small manuscripts which had no ornament on them at all. When the ornament had to be produced it was done by a generation which had grown up quite independently, which knew nothing of the beautiful books of the Roman Church, and which was cut off from the books of the Roman Church by a difference of ritual. When they started the ornament they had to adopt the ornament of their own metalwork; and the illumination in the book was a copy of pre-existing metal ornament which was perhaps connected with the Norse ornament. Mr. Herbert had worked the history out in an excellent way, and he thought that point ought to be borne in mind. It was difficult to raise any discussion on the paper. The author had given so complete an outline, and at the same time had so carefully avoided any of the points that were not yet settled, that it was only possible to compliment him on his dexterity as well as his knowledge. He regretted very much that the author had not shown any slides of the "Exultet" Rolls. There was in the Museum a most beautiful roll, to which the author had referred, relating to a little service introduced into Monte Cassino in the thirteenth century on one of the early Sundays in Lent. It was then the custom to sing a number of Psalms, and on each Psalm being sung a candle was put out; and on turning over each of the rolls magnificent illuminations of the scene were found. He knew nothing about them until Mr. Herbert's book appeared, and when he subsequently inspected the rolls it seemed to him that the rise of Giotto and the whole of his school was explained. Giotto and his school in painting were practically without father and mother in the history of art, but in looking at the "Exultet" Rolls the real origin of the school was apparent. He would have been very glad indeed to have seen slides of those rolls among the pictures the author had shown.

THE CHAIRMAN, in proposing a hearty vote of thanks to the author, said it was impossible to do so without referring, as Mr. Steele had done, to the extraordinarily beautiful set of slides that Mr. Davenport had shown. The skill which had been displayed in their production was almost equal to that of the old illuminators themselves. The next thing Mr. Davenport ought to do was to illuminate a book, and to revive an art which deserved reviving.

The resolution of thanks having been carried unanimously,

MR. CYRIL DAVENPORT, in reply, thanked the audience for the vote of thanks they had accorded to him. He was very pleased to hear the chairman's remarks with regard to the Book of Kells and the Lindisfarne Gospels, because they rather echoed what he felt himself. A very great authority, Professor Westwood, had said, however, that the

Hosted by Google

Book of Kells was a finer piece of work than the Lindisfarne Gospels, and that was why he did not like to say it was not. He wished to thank Mr. Robert Steele for his very able contribution to the discussion, and promised him that before he heard the lecture again he would be able to show him a very good slide of an "Exultet" Roll.

MR. ALAN S. COLE, C.B., writes as follows:—"I am sorry that a bad cold prevents me from attending the meeting this evening, when Mr. Davenport is to read his interesting and valuable paper on Illuminated Manuscripts, an advance copy of which I have had the advantage of reading. Had I been able to be present, I should have ventured to point out their value in throwing light upon sources of design for embroideries and tapestries, etc. I made some allusion to this in the Cantor Lectures which I delivered in 1905, since when I have been fortunate in having under my hands some of the finest illuminations known. One of the most elaborate pieces of embroidery in Europe is the so-called Dalmatic of Charlemagne, preserved at St. Peter's, Rome. It has been much discussed, and its work attributed to a period of from two to four hundred years later than Charlemagne. But the illuminated Sacramentary given about 826 to the Archbishop Diogo of Metz, and the Vivianus Bible presented to Charles the Bald about twenty years later, seem to prove that the magnificent design for the Dalmatic may quite well have been produced in Charlemagne's time, and that the tradition of the Ecclesiastics at Rome has greater claim on belief than the opposing opinions held by the erudite antiquaries. Again, it is equally interesting to note that the famous worsted embroidery on linen, commonly called the Bayeux Tapestry, displays incidents of the Norman Conquest represented in a style identical with outline drawings in Œlfric's Pentateuch of the eleventh century in the British Museum. Many thirteenth and fourteenth century illuminations seem to have been the sources of supply for groups of figures in embroideries like the well-known Syon Cope, and even stained-glass panels like those of the Pricke of Conscience window at York. Designs for tapestry wall-hangings have certainly been derived from illuminations. Hennequin or John of Bruges adapted from a manuscript belonging to Charles V. of France representations of various subjects in the Apocalypse, which were in due course woven in tapestry for the Duke of Anjou, and supplied by the Paris merchant, Nicolas Bataille, in instalments between the years 1376-90. The greater part of this set of tapestries is now in the cathedral at Angers. Some fifty years later Jehan Foucquet, to whom Mr. Davenport has given particular mention, painted the superb full-page illuminations of the 'Grandes Chroniques de France'—now in the Bibliothèque Nationale—which are highly suggestive of designs for tapestry. But, besides these, there are in the Louvre a set of monochrome drawings, about ten inches by seven, attributed to Jehan Foucquet, illustrating events in the Siege of Troy. At the Victoria and Albert Museum we have a hanging 21 feet by 13 feet which reproduces one of these drawings—the one relating to the coming of Queen Penthesilea and her Amazons to the assistance of King Priam. Enlargements on so large a scale, and for decorative stuffs in demand for religious and lay purposes, contributed to the great development in the fifteenth century of the practice of drawing and painting then arising, which, however, the art of illumination had nurtured on a smaller scale for over some thousands of years previously."

THE QUEBRACHO WOOD INDUSTRY OF PARAGUAY.

The word quebracho is a contraction of the colloquial Spanish and Portuguese term, "quiebra-hacha," originally applied to many trees in Latin America. It means a "breaker," and the character of the timber is implied in this meaning. Species of the quebracho tree are to be found growing in the Chaco country of Paraguay, Brazil, and northern Argentina, the red coloured being the one containing tannin, used in the manufacture of the extract so valuable in the tanning of hides. It is used also for furniture. Every portion of the tree is utilised for the extraction of tannin. In Paraguay and the Argentine Republic the wood is a valuable asset, the land bearing the trees selling from £600 upwards per square league. During one year Paraguay manufactures many thousand tons of extract, and the United States imported in 1910 over £850,000 worth of quebracho for tanning and other purposes. Much of this wood comes from the Chaco region of South America, which belongs to both Argentina and Paraguay, but the largest area is part of the latter country, and it grows wild in all parts. Gathering quebracho is now a recognised industry, and so extensive has it become that even railways are pushed into the wilderness to facilitate the ever-increasing supply to market, while steamers travel up the rivers emptying into the Parana so as to be on hand to receive the wood or the extract as it is brought from the forest, and whole settlements gather and leave permanent traces over this immense tract of Paraguay where quebracho grows. Quebracho may be cultivated, although the tree is of slow growth, but the necessity for that step may arise if the demand continues. In addition to its great value as furnishing tanning material, the tree is of great service in railway and fence construction in South America, for the wood is extremely hard and seems to be the only material immediately available for sleepers; its reputation has spread so widely that many sleepers are at present being exported to Europe. The industry of extracting tannin from quebracho had its origin in France, where a consignment of logs was sent from Paraguay in 1874. The first factory in South America for the manufacture of the extract was erected at Puerto

Hosted by Google

Casado, Paraguay, in 1889, followed a few years later by others, to support which thousands of leagues of quebracho land in the Paraguay Chaco were bought.

AREA AND POPULATION OF THE GERMAN COLONIES.

The colonial extension of Germany is of comparatively recent growth. Previous to 1880 the colonies were unimportant, and it was not until after the death of Prince Bismarck that the colonial policy of the German Empire has been to extend her possessions beyond the seas.

According to the latest statistics, the colonies of Germany cover an area of 2,658,500 square kilometres (1,026,181 square miles), with a population of 13,943,970, or only 5·25 persons per square mile. The proportion of whites to the native population is also very small, being only one to 580.

The areas and population of the various colonies are as follows:—

AREAS.

	Sq. Kilometres	Sq. Miles.
East Africa	995,000	384,070
South-East Africa	835,100	322,348
Cameroons	495,600	191,302
New Guinea	240,000	92,640
Togo Land	87,200	33,659
Caroline Islands	2,476	956
Samoa	2,572	993
Kiao-Tcheou	552	213
Totals	2,658,300	1,026,181

POPULATION.

	Native.	European.
East Africa	10,028,000	3,756
South-East Africa	69,000	12,935
Cameroons	2,302,000	1,284
New Guinea	301,000	688
Togo Land	1,000,000	372
Caroline Islands	20,000	566
Samoa	35,000	473
Kiao-Tcheou	165,000	3,896
Totals	13,920,000	23,970

The total value of the trade with these colonies is estimated at 255 million marks (£12,750,000), of which 115 million marks (£5,750,000) represent the imports, and 140 million marks (seven millions sterling) the exports. Taking into consideration that in these amounts Kiao-Tcheou figures for 100 million of marks (five millions sterling), the value of the trade of the German colonies must be considered insignificant when compared with their extent. The value of the imports of Germany to her colonies, although showing an increase from 25 million marks in 1900 to 42 million marks in 1909, only represents about one half of the total import trade. The export trade, although it has increased considerably during the last ten years, does not appear to have benefited German ports to the extent that might have been anticipated, a large proportion being with other countries.

THE PRODUCTION OF OATS AND BARLEY IN FRANCE.

The production of oats and barley in France during 1911 shows an increase on that of 1910. The following official statistics, published by the Minister of Agriculture, show the areas cultivated and quantities produced of these cereals.

AREAS CULTIVATED.—OATS.

Year.	Hectares.	English Acres.
1911	4,040,100	9,979,047
1910	3,951,300	9,759,711
Increase	88,800	219,336

QUANTITIES PRODUCED.

Year.	Hectolitres.	Bushels.
1911	107,288,400	295,043,100
1910	102,469,000	281,789,750
Increase	4,819,400	13,253,350

The average yield is 26·55 hectolitres of oats per hectare (29·56 bushels per acre) in 1911, as compared with 25·93 hectolitres per hectare (28·88 bushels per acre) for the whole of France in 1910.

The quantity of barley was:—

AREAS CULTIVATED.

Year.	Hectares.	English Acres.
1911	774,425	1,912,829
1910	748,480	1,848,745
Increase	25,945	64,084

Hosted by Google

QUANTITIES PRODUCED.

Year.	Hectolitres.	Bushels.
1911	17,201,240	47,303,410
1910	15,321,300	42,133,575
Increase . .	1,879,940	5,169,835

The average yield is 22·21 hectolitres per hectare (24·75 bushels per acre) in 1911, and 20·47 hectolitres per hectare (22·8 bushels per acre) in the previous year.

ARTS AND CRAFTS.

Lettering.—The most fastidious amongst us have been congratulating ourselves of late on the improvement which has undoubtedly taken place in recent years in lettering of various kinds—printed, carved, painted, and written. Not only are notices, titlepages, signs, etc., far better than they were even a few years ago, but posters and other kinds of advertisements are, as a rule, far less offensive than they used to be, and are sometimes quite pleasing to look upon. Again, as a result of the teaching of script in the art schools, it is now quite common to see addresses and simple pieces of writing well spaced, good in form and generally satisfactory. The writing usually taught in schools of art, however, has very little to do with the kind of current hand which is necessary in the everyday affairs of life, and it is by no means unusual to find that the ordinary handwriting of a student who writes really beautiful script, is poor and weak, if not appallingly bad. Perhaps the gulf between the two sorts of writing is responsible for a state of affairs in one of the departments of lettering which can only be described as deplorable.

Many of the senders and recipients of Christmas and New Year cards are too intent upon the wishes conveyed in them to pay very great attention to the form in which they are presented; but anyone really interested in lettering, printing or writing, could hardly fail to be depressed after turning over a dozen books full of this season's greeting cards. The carefully printed, embossed or engraved words which formed part of the decoration of the front page were sometimes (though by no means always) quite adequately rendered, but the more personal wishes within were, for the most part, extraordinarily badly done. When Roman capitals had been made use of, or some other ordinary printing type, the result was sometimes fairly satisfactory, though often enough the fount employed was by no means the best; but when it came to current hands and formal writing of various sorts the work was poor beyond all expectation or forgiveness. The hands used were usually cramped and stilted, and quite unharmonious, whilst the flourishes were for the most part altogether meaningless and added apparently at random. Finally, the taste which should have been apparent in the setting out of the page, was too often conspicuous by its absence. It is comparatively easy to understand the point of view of the person who dislikes and will have none of what he describes as "fancy writing," but if we are to have decorative, or indeed formal, writing at all, it should surely be based on good models. The old writing masters had many failings, especially the later ones, and some of these perpetrated work which no one in his senses would wish to drag from the well-merited oblivion in which it is buried; but amongst the others are men like Palatino, Yciar, De Beaugrand, and Davies of Hereford—to mention at random only a few—who have much to teach to those willing to learn. If the training of the people who are going to do this kind of work included a study of a few of the best hands of earlier writing masters, things would at least be less bad than they are at present. When we turn to the cards, whose ornamentation consists almost entirely of lettering, much the same state of affairs is observable. Those which depend on current or cursive writing are generally thoroughly unsatisfactory—lacking in spontaneity as well as in grace of line and daintiness of composition. For some years past, however, a certain number of cards, well and tastefully written in half uncials and Roman characters, have been issued, and these continue, as far as the lettering pure and simple is concerned, to be quite adequate; but the revival of illumination has had rather a bad effect upon them. It seemed to be essential this year that they should begin with an illuminated initial, and that as a rule some further ornament should be added. Now a really beautiful illuminated initial is in itself one of the most satisfying forms of decoration, but the combination of such an initial with the remaining text and its relation to the page as a whole is a matter which always requires very careful consideration—even more consideration when the page is small and the text short than in the case of a closely-written quarto or folio—and it is just this point which has been overlooked by the Christmas-card writers and illuminators. They have generally overweighted their text with unwieldy initials and overloaded it with superfluous ornamentation. Now the ordinary student has been carefully taught to do script nowadays, and he quite often does it very well, but when he tries to combine it with illumination and adapt it to a Christmas card he too often fails. Perhaps some people would say that is because he has been taught too much; but is it not at least as likely to be because he has not been taught enough? We talk a great deal just now about originality and allowing the student to find his own way, but we neglect to furnish him with the necessary outfit for his journey. After all, there is such a thing as taste, and unless a man learns something about that his artistic equipment is lacking in an absolutely essential feature. It is sometimes said, with a certain amount of truth, that taste cannot be

Hosted by Google

taught; but it can be cultivated, and it should be the business of the schools to set about doing it.

Arts and Crafts and Home Industries in Italy.—The more one sees of Italy the better one realises that an arts and crafts movement, as we in England understand it, not only does not, but cannot, at present exist. The movement with us was necessitated by the decay of the artistic crafts, which, owing to various causes, mainly economic, were felt to be altogether in a bad way. It was, at the outset, essentially a movement of artists—mainly of designers and architects—who turned their attention to reviving various crafts which seemed in danger of being either extinguished or entirely swallowed up by manufacture; and though none of the original movers made fortunes by their efforts, some of them at any rate earned quite a comfortable livelihood. In Italy the case is quite different. With the exception of Milan, which is more or less like any other big city, the Italian towns have retained their own characteristics to a very marked degree, and along with them their own artistic industries. Some of these may be, from the point of view of art, in rather evil case, and others are being more or less ruined by foreign tourists of different nationalities, very ready to gush over characteristic work, and quite unwilling to pay for really good workmanship. But the industries, such as they are, remain, sometimes conducted on a fairly large scale, but quite frequently carried on by small men, who employ half a dozen hands or so, and are content with a very modest livelihood, and while this is the case there is little or no chance for artists who take to handicraft to earn what they would be likely to consider a living.

But whilst an arts and crafts movement is to seek, there is a very strong effort in favour of home arts and industries, although it is unlike our British movement, in so far as it is practically confined to women's work, and consists mainly in an attempt to revive or keep alive amongst the peasant women throughout Italy their own traditional needlework. Some of this work is, of course, famous throughout the world. Who has not heard, for instance, of Venetian point? And at various exhibitions in London we have had opportunities of seeing the beautiful drawn threadwork which comes from Æmilia, and (since the Messina disaster) some of the Sicilian industries. But work is being done in Tuscany and Umbria which, though it is less well known, is extremely interesting, and distinctly recalls some of the most unusual work in the Bargello—that in coloured silks on a white or écru linen ground. The ground stuff is left to form the pattern, which stands out in white against a worked background of red, green, brown, or blue as the case may be. It is in this combination of white and colour that the north and central Italian embroidery and drawn threadwork seems to excel. White work is for some purposes unrivalled, but embroidery in colour on white linen offers a far greater scope to the worker. The Sicilian needlework, however, is perhaps the most interesting of all, and large quantities of it are being done. One comes across a piece of coloured work now and again which might well have come from the Greek islands, but the embroidery as a whole is entirely white, and includes, besides beautiful drawn threadwork of the type of Greek lace, that much more unusual work in which, while no threads are drawn out, the background is formed by drawing the threads tightly together into a simple lattice pattern, whilst the design stands out from it in the plain material. Some of the patterns executed by this method, though they are supposed to be copied from Saracenic originals, are too incoherent to be very satisfactory, but the workmanship is extremely interesting. It is rather odd that in places so far apart as Umbria and Sicily, and in such very different kinds of work, the same unusual practice of working the ground and leaving the pattern plain should obtain, though the designs in both cases rather suggest that they may, at some period or other, have been derived, or at any rate influenced, from an Oriental source.

EMPIRE NOTES.

The Royal Visit to India.—In His Majesty's message to the Prime Minister, on the eve of his departure from India, referring to the success of his and his gracious Consort's visit to that great Dependency, he says: "This satisfaction will be still greater, if time proves that our visit has conduced to the lasting good of India and of the Empire at large." In this hope all Imperialists will share, as the welfare and prosperity of India are bound up with the welfare and prosperity of all the oversea Dominions and Dependencies of the British Crown. The importance of the step taken by His Majesty in holding a Durbar in India, to say nothing of the changes which, on the advice of his Ministers, he announced, cannot but have a great and, it is believed, a permanently beneficial influence upon the peoples of that country, bringing them into closer union with each other, under British rule, and promoting the spirit of loyalty to the British throne.

The Congress of Imperial Universities.—Arrangements for holding the proposed Empire Universities Congress, which have been in progress for the last twelve months, are rapidly approaching completion. The meetings are to be held in London from July 2nd to the 6th, and it is hoped that the fifty-two Universities scattered throughout the Empire will all send delegates. Although only four days are allotted for the meetings, the oversea delegates, for a fortnight previous to the Congress, will be the guests of the Home Universities, and will have the opportunity of visiting these great seats of learning, and of studying, on the spot, the methods of teaching and administration in operation therein. This of itself will be most

Hosted by Google

useful, both as a preparation for the Congress and as a means of bringing together the heads of the Home and visiting Universities. There are two committees charged with the duty of arranging for the Congress, and of receiving the delegates. Among the members of these committees are the Secretary of State for the Colonies, and the High Commissioners and Agents-General of the various Dominions. The Prime Minister, the Leader of the Opposition, and the Archbishop of Canterbury, besides a number of University leaders, are also members. Dr. Alexander Hill has been appointed general secretary. The Congress will discuss the important subject of improving the relations of the various Universities to one another; it will review the whole question of higher education within the Empire, and efforts will be made to give a practical issue to the discussion.

The Imperial Emigrant and his Political Religion.—Under this somewhat singular though attractive title, there is an article in this month's *Nineteenth Century*, from the pen of Mr. Arthur Hawkes, the Canadian Special Commissioner, sent to England to study the immigration policy of his government from this side of the water. "My mission," Mr. Hawkes says, "is to ascertain what methods are being followed by the Dominion and Provincial Governments to obtain immigrants, and to propose measures for more effective co-operation between them, with a view to increasing permanently the flow of immigration to Canada." In doing this, he proposes, by his article and any addresses he may deliver, to present to the British public "the emigrant, as the real custodian of the Empire's future, the living epistle of the only political religion that can preserve British unity throughout the world." From this point of view, he regards the emigrant as so important a factor in the growth and development of the Empire that he would fain make the average home-staying Briton become, for the moment, "even as an emigrant, that he may know the things that make for the glory of the country to which the emigrant goes, and the influence of that country on the one he is leaving." How far the writer may succeed in his purpose it is difficult to say, but that it is desirable for those who wish to promote the progress and unity of the Empire, but who themselves have no intention to emigrate, to view the question from the emigrant's standpoint, both on his outgoing and on his return to revisit the homeland, there can be no question. In any case, emigration to our oversea Dominions is a subject that needs to be carefully studied, especially in view of our congested districts, if we are to people the empty spaces of Canada, Australia, and South Africa with the British born, and, at the same time, to relieve the pressure of over-population at home. It is to the populous centres of the United Kingdom rather than to our country districts—which are being sadly depleted by migration to the towns as well as by emigration to our oversea Dominions and to foreign countries—that the attention of those who, like Mr. Hawkes, are desirous of inducing our people to emigrate, should be turned.

Canada and the New Year.—An interesting consensus of opinions as to Canada's new year's prospects, has been issued in a leading London Canadian paper, in which Canadian representatives of trade and commerce, one or two Premiers, and Ministers of Agriculture and Labour have taken part. According to these writers, the outlook of 1912 is full of promise. The President of the Canadian Bank of Commerce says: "The new year could hardly promise better for Canada. Immigration, railroad building, improvements to towns and cities, enlargement of factories, Clearing-House returns, the revenues of the Dominion Government, foreign and domestic trade, are all on a larger scale than ever before." The president of the Grand Trunk Railway system says, "the railways are showing larger increases in their gross receipts than is the case with the railways to the south of us, while in every branch of industry there is marked activity and increased business." A concrete illustration of this promised development is afforded in many of the new townships that are springing up along the railway lines, as, for example, in Red Deer, a town in Alberta, through and in connection with which three trans-continental and three branch lines are being constructed, making in all eleven lines now converging upon that town. As in its immediate neighbourhood there are the largest and most important coal deposits known in Canada, which will be tapped by one of the lines now in construction, Red Deer is likely to become an important industrial as well as agricultural centre. The same may be said of other towns in all the provinces, not excepting the Eastern Provinces, in which a progressive policy of railway development and land settlement has been adopted.

Victoria's Irrigation Lands.—Reference has been made in these columns to the various irrigation schemes of Australia, and, in passing, Victoria has been noticed. One prominent factor, however, in regard to the advantage to the settler afforded by these irrigation farms has been somewhat overlooked, which is that irrigated land is ready for occupation, so that the settler can commence farming operations immediately on his arrival on the land he has selected, or which has been selected for him. In the case of most non-irrigated Government land in Australia, the newcomer is called upon to perform years of arduous toil before his holding can be profitably worked, and thus valuable seasons are lost. Apart from this, farming is, of course, safer in irrigated than in non-irrigated districts, in view of occasional dry seasons. The Victorian Government is now renewing its efforts to secure applicants for this class of settlement, and a new departure in emigration to Australia will shortly be made in the form of conducted parties for intending settlers with capital. Arrangements for this purpose have been made with one

Hosted by Google

of the leading shipping companies to grant a reduction in its saloon fares, by a boat leaving in the course of the next three or four months, in order to afford land seekers the opportunity of making a comfortable voyage to Australia. A pamphlet has recently been issued by the Victorian Land Commissioner in London, which points out what can be done by men with small capital, and by young men who intend taking up farming life, who will receive instruction in general farming, not only without fees, but with the promise of a small wage to be paid by the farmer, which will range, according to ability, from 5*s.* to £1 per week with maintenance.

Orange-growing in Western Australia.—One of the best districts in Western Australia for orange growing is known as Harvey. This district is situated in the south-west division of the State, at the foot of the Darling Range. From a picturesque point of view it is one of the finest in Australia, especially when the orange trees are in blossom. Oranges of all kinds have been successfully grown there for many years, and for size and flavour the Washington navel orange of Harvey is unequalled by any in the world. At Harvey the trees are cultivated in a highly scientific manner, and no trees are allowed to grow untended. Western Australia as a market for deciduous fruit has yet to be exhausted, and it will probably be some years before large shipments of oranges will be sent to London. Europe will be able, when the time comes, to take as many oranges as Western Australia can send, as the export season is at the time when such fruit would be in keen demand. For some time past the Government of Western Australia has had under consideration a large scheme of irrigation for the south-west division. Whilst the rainfall of that State is one of the most certain in the whole of the Australian Continent, it is felt that better results should be obtained from the land than hitherto. It is suggested that a commencement should be made in the Harvey district, as it lends itself admirably to irrigation, since it is possible to lock large volumes of water in the local hills by diverting the sources of the Harvey River in the winter into land-locked dams. There is one particular hollow in which, were a wall built on one side, thousands of millions of gallons of water could be stored. From its position water could be articulated for many miles over the eastern district of the south-west division, in which are some of the finest wheat lands of Australia. On the west and south-west side of the ranges are also some splendid fruit and dairy lands, the value of which would be considerably enhanced by the introduction of irrigation. On this subject a deputation of Harvey growers recently waited upon the Minister for Agriculture to urge immediate action. At Brunswick, about twenty miles from Harvey, a small irrigation scheme has been in successful operation for some years; the experience gained from this will be of great value to the Government in undertaking a larger scheme.

New Zealand's Revenue and Prospects.—According to a recent cablegram, the revenue of New Zealand, for the nine months ending December 31st last, shows an excess of £598,000 over the total for the corresponding period of 1910. This is an interesting and, indeed, a striking fact, read in the light of certain statements made in a recent article on some aspects of New Zealand life and legislation. Evidently, notwithstanding some defects inherent in all human affairs, the general progress and the continued prosperity of that Dominion are not greatly affected by the legislation, much of which is of an experimental character, in which the Parliament of that country has indulged during the last few years. Referring to the above statements, the High Commisioner, Sir William Hall-Jones says "There is no country in the world which exports as much per head as New Zealand." He further affirms that a great deal that has been done has "wrought substantial change for the better in the condition of the working classes," and he cites the factory laws as an example. A comparison of the financial condition of New Zealand to-day, with what it was a few years ago, cannot but be gratifying to New Zealanders. In 1904, for example, the bank deposits, other than those in savings banks, amounted to 19 millions sterling, while in 1909, the latest return available, they stood at just under 22 millions, and, what is a still more satisfactory indication of the general prosperity of the people, the savings banks depositors in 1909 numbered 408,770, and the total deposits amounted to over 14 millions sterling, or an average of £34 8*s.* 2*d.* per depositor, or £14 6*s.* 3*d.* per head of population. In all directions—industrial, agricultural, educational, and social—as far as these can be judged by reports and returns, there appears to have been a continuous and remarkable development in the prosperity of the country.

CORRESPONDENCE.

SACRED FISHES.

Some correspondents having been interested by the casual statements made by me of the veneration in which certain fishes were held by the now dead nations [Egypt, Babylonia, Israel, Greece, and Rome] of the Old World, and still are held by India, the only living integral survival of historical antiquity, and its fullest and truest interpreter [even before scattered and peeled Israel], reported in connection with Dr. Travis Jenkins's lecture on "The Fisheries of Bengal" in our *Journal* of December 22nd, it has seemed to me desirable to supplement what I then incidentally said, by this systematic and comprehensive Note on the subject; in the writing of which I have chiefly

Hosted by Google

relied on such readily accessible authorities as the Bible, Homer, Herodotus, and Aristotle, and Pliny and Athenæus,—the information accumulated by the two last being overwhelming; at the same time overlooking nothing of pertinence to the question recorded by Plutarch ["Isis and Osiris"], Lucian ["The Syrian Goddess"], and Appuleius ["Magic"].

The earliest patent historical indications of the sanctity of specified fishes is afforded by their being held *tabu*, or "forbidden" for food, because they were *totems*, or reputed [Darwinian] ancestors, and hence heraldic signs, of certain tribes and peoples; and, where this explanation of their sanctity was lost, by their being held "an abomination," as by Israel to this day [Levit. xi. 9–12, and Deut. xiv. 9–10]; and assuredly not—not in the instances of fishes—because of their being regarded as unwholesome food: the other explanation in this connection of the sanctity of fishes being traceable, in casual cases, to statecraft, or priestcraft, or the cunning of individual epicures and fishmongers. Further Biblical references to the worship of fishes are to be found in Exodus xx. 4, and Deut. iv. 18, where Israel is adjured not to make any graven image in gold or silver, in the similitude of any figure, the likeness of male or female, of any fowl that flieth in the heaven above, or beast that is on the earth beneath, or of any fish that is in the waters under the earth, "to bow down to them and serve them" [after the manner of the surrounding pagans]; and again, possibly, in the mention, Song of Songs vii. 4, of "the fish ponds in Hesbon"; and (if the verse is rightly translated) in the judgment prophesied against Egypt, Isaiah xix. 10,—"And they shall be broken in the purposes thereof all that make sluices and ponds for fish."

Herodotus tells us [II. 77] that many kinds of fish were eaten by the Egyptians; and [II. 72] that two kinds, the Lepidotus and the Eel ["Phagrus"] were sacred throughout the Nile; while from Plutarch we learn that the "Latus" was held especially sacred at Latopolis, the "Oxyrhynchus" or "Pointed-Nose" at Oxyrhynchus, and the Eel at Phagroripolis, and Syene; it having been constituted an object of special worship at the former city in order to induce its inhabitants to keep the irrigation canals from the Nile in better order. The fish was also regarded in Egypt as a symbol of Isis, the wife of Osiris; the goddess, with their son Horus in her arms, being sometimes represented with a fish surmounting her head; and Horus himself as standing on a crocodile, and holding a fish above the aureole encircling his young head; both representations having, probably, as their immediate purpose, an astronomical significance.

Passing from the Nile to the Tigris and Euphrates, we find the myth of the Fish-man deity, Oannes [so named by Berosus, the Euahanes of Hyginus, Aos of Damascius, Oēs of Helladius, Hea (Fish-woman) of the Chaldæans, and Ea of the Accadians], coming up out of the Indian Ocean, and introducing the characteristic civilisation of Chaldea [afterward Babylonia] and Assyria, throughout Mesopotamia. This Protean (now masculine and again feminine) divinity has been identified with the similar Fish-man god Dagon [1 Sam. v. 2–7] of the Philistines; and with Derceto, or Atargatis, the Aphrodite Ourania of Herodotus, the Fish-woman goddess of the Syrians. But while, in our present imperfect knowledge, we must apply to this identification the caveat, "quod scis, nescis," the parallelism between all these Fish-human forms, as objects of ichthyolatry, from beyond "the river of Egypt," up to the confines of Persia, suffices for the purposes of this Note. Ninua, the daughter of Hea has also been identified with the city of Nineveh; its name [cf. Nun, "the Fish," a name of Hea], meaning, according to some, the City of "Fish-dwellers"; and the myth of Jonah, that reads so incongruously among the canonical scriptures of Israel, has immediate reference to Nineveh as a centre of Euphratean fish-worship; and although Jonah means "Dove," the dove and the fish are interchangeable as hierophallic symbols, and are absolutely consorted in the myth of the descent of Semiramis [Sammuramat] from Derceto or Atargatis. It is in the light of these fables that the full meaning of the Saviour's reply to the Pharisees and Sadducees becomes so clear:—"A wicked and adulterous generation seeketh a sign, but there shall be no sign given them but the sign of the prophet Jonas [Matt. xvi. 4]"; and again:—"The men of Nineveh shall rise up in judgment with this generation; for they repented at the preaching of Jonas, and behold a greater than Jonas is here" [Luke xi. 30]. The modern name of Nineveh, Mosul, if altogether of Arabic origin, can only mean, Place of "Confluence"; and any sort of conjunction, coupling or pairing [even as of the two lips, two nostrils, etc.] is a sacred thing ["juncta juvant"] in Hindu, and all pagan mythology. But I have before now drawn attention to the fact that Masulipatam, on the Coromandel coast of India, immemorially in coasting commercial communication with the head of the Persian Gulf, and so closely, as alone sufficient to explain the influence of the art of Babylon and Nineveh on its famous chintzes, as on the hangings of the temples of Southern India alike on the Coromandel and Malabar coasts, and on the sumptuary pile carpets, denominated, by European importers, "Malabar carpets,"—that the name of this town, correctly spelled, Machli-patam, also means "Fish-town." Again, Matsya, the Sanskrit word for "Fish," and the denomination of the "Fish-Incarnation," the very first *avatar* or theophany of the Lord Creator Vishnu, is also one of the most ancient and sacred names of India, as Fruitful of "Fish"; the direct reference undoubtedly being to the wealth of the Bay of Bengal in fish, particularly about the mouths of the great rivers that debouch into it; although some consider this name to refer also to the countries, Kathiavar, Gujerat, etc., about the Gulf of Cambay. The root of the word *matsya* is *mad*, "joyousness," "liveliness," "gaiety," "intoxication" [compare *madad*, an "opiate pill," and Madana, the "Goddess of Love," "Delight," etc.]. When I returned to Bombay in 1854–5, a story was

Hosted by Google

current there of a Lord Stanley ["the Rupert of Debate"?] having been there some time before and putting up in Colaba simply to eat Pomfret. If true, the story should not be let pass into oblivion. But the most fascinating fish in all India is the "Bombay Duck," in that up to this date it has defied all attempts convincingly to demonstrate the etymology of its endearing name. It is probably of the same category as such names [of herrings] as "Yarmouth Capons," and "Digby Chicks."

Crossing over to Italy and Greece, Pliny says, VII. 2 (1), that the Indians dwelling west of the Indus "know no food but fish"; IX. 22 (16), that "auguries are derived from fishes; IX. 80 (54), that after the death of L. L. Lucullus, surnamed Murena, from his love of that fish, the stock in his ponds sold for about £32,000; and IX. 80 (55), that the fish-pond of C. Hirrius was sold for a like sum,—instances of the many flagrant vulgarities that tainted, and at last undermined and overthrew "the grandeur that was Rome"; XXXII. 7 (2), that "in the Fountains of Jupiter at Labrauda [in Caria] there are eels which eat from the hand, and wear earrings; also at Chios, at the Temple of Old Men ['senum delubrum'] there; and at the Fountain of Chabura ['the Fountain of Juno'—*i.e.*, Atargatis, of XXXI. 22 (3)] in Mesopotamia"; XXXII. 8 (2), that, "at Myra, in Lycia, the fish in the Fountain of Apollo . . . give oracular responses, when thrice invoked by the sound of a flute . . . and that at Hieropolis [Bambyce, Mabug], in Syria, the fish in the Lake of Venus [Atargatis], bedecked with jewelry of gold, answer to the call of the temple attendants"; and XXXII. 10 (2), that, "Numa Pompilius forbade the serving up of fish without scales at the festivals of the gods . . . with the intention that banquets, both public and private, and the covers laid before the gods, might be more economically provided for the future; and also to preclude the risk of the caterers on such occasions forestalling the market, and raising the price of the fish required"; and Athenæus, after giving, I. 22, the names of eight writers on fish, says, III. 85, that the fish of all kinds caught at Byzantium were stated to be superior to all other fish taken elsewhere [in the Mediterranean and Euxine]; VII. 18, quotes from "the Telchinian History":—"What are called sacred fish are the Dolphin and Pompili" [compare Anglo-Indian Pomfret, and see Yule's "Glossary"]; himself adding, that "it is an exceedingly libidinous fish, sprung at the same time with Aphrodite from the foam of the sea [a euphemism for the matter that flowed from the mutilated Cœlus, or his son Saturn]"; VIII. 2, that in certain places where there is no overflow of rivers, small fishes are at times found in deeply dug ditches, as in Paphlagonia, where they are called "fossil fish"; VIII. 4, quotes from Theophrastus that there are in India fish that leap out of the rivers, on to their banks, and then back again into the water, "just like frogs"; VIII. 7, that when Sarpedon, the general of Demetrius, was, just after his defeat near Ptolemais by Tryphon, delivered from utter destruction by a sudden wave from the sea swallowing up his victorious enemy, he sacrificed incredible quantities of fish to Poseidon; VIII. 10, that Nemesis was metamorphosed into a fish; VIII. 36, that Apollo was honoured among the Eleans under the title of "Fish-Eater"; and that in the temple of Diana at Pisa, Neptune was represented as offering a parturient tunny to Jupiter; while in VIII. 37, he gives the following account of Atargatis: (1) from "Antipater of Tarsus, that among the Syrians," no one could eat fish without Gatis being invited [ἄτερ Γάτιδος], whence the common people, taking her name to be Atergatis, abstained altogether from eating fish; (2) from Mnaseas, that "Atergatis was a bad queen . . . and forbade fish to her people, because she had such an appetite for fish herself," and hence the custom still continues among the Syrians when praying to her, to offer her similitudes in gold and silver of fishes; and also real fish, daintily cooked, which the priests and the goddess eat themselves; and (3) from Xanthus the Lydian, that Atargatis, "being taken prisoner by Mopsus, King of Lydia, was drowned, with her son, in the lake [one of the holiest of her fish-ponds] near Ascalon . . . and was devoured by the fishes therein." My last extract, from Athenæus, shall be the irrelevant one of the last two lines of his quotation from Alexis, which I translate here, simply as an affectionate tribute to him as a learned and most truly companionable opsologist:—

"Eat fish, and drink like fish, to the full of your lust:—
Pericles, Codrus, Cimon, they all are but dust!"

It will be recalled also, and with sympathy, how the Children of Israel, when they went out ["on strike"] into the desert of Sin, soon "fell a-lusting" after "the flesh-pots of Egypt," "the fish which we did eat in Egypt freely" [Ex. xvi. 3, Num. xi. 4, 5]. It is also a suggestive fact that although most of the Greek words compounded of ὄψον, "a dainty," refer to dainties and dainty cookery generally, they would seem to refer especially, at least in ancient Athens, to fish and its cookery; thus, ὀψοπώλης is "a fishmonger," ὀψωνέω to "buy fish," ὀψωνία "purchase of fish," ὀψωνόμος, inspector of [prices of] fish," ὀψοφάγοι, "fish-eaters," and ὀψοφαγίστατοι, "fond fools after fried fish."

The vestiges of ichthyolatry to be traced in the remains of the ancient art of the West, although fewer than the evidences of it sequestered in our ancient literatures, are now better known than the latter, owing (1) to the wide circulation given during the past eighty years to the results of antiquarian research in Egypt, and Mesopotamia, and Anterior Asia, and Greece,—the figure, in particular, of the Euphratean Fish-man god so frequently seen on the cylinders [for sealing letters] of Babylonia and Assyria, being now familiar throughout Europe and America; and (2), to the perpetuation of the Fish-woman figure as a charm in the peasant jewelry of Southern Italy. The Greeks, with

Hosted by Google

whom, in art, we must include the Romans, were instinctively repelled by the unnatural conventional and symbolical forms of the popular divinities in Egypt and Mesopotamia; the tendency of their genius having been to represent them by the most highly inspired artistic expression that could be given to natural forms, above all, to the human form, by the graver, the chisel, and the brush; until, for examples, their Zeus, and their Athene, were perfected to the realisation of the ineffable ideals of Homer and of Phidias. No Greek jeweler, sculptor, or painter, not even the depraved "pilferers of minium," and "painters of dirt" [πορνογράφοι], would have prostituted and degraded their art to the reproduction of such monstrous personifications of their greater gods, as the "Bull-headed Dionysos," the "Horse-headed" Demeter, and the "Horse-man" Poseidon; notwithstanding that the crude and repulsive archaic images of these divinities may have indefinitely continued to be venerated by the common herd of their worshippers. It was only the minor mythological beings that the Greeks ever rendered in the composite iconography of the original Oriental conceptions of them; and even then they refined them to the uttermost by the severest artistic draughtsmanship of their strange symbolical features, as in the instances of the Centaurs, Pegasus, Pan and the Satyrs, Scylla and Charybdis, Geryon and, if they may be added, the Chimæra, and the ever loathsome Harpies; while the sacred fishes appear in Greek art either, in their real and true shapes, like the Dolphin at the beautiful feet of statues of Aphrodite, and the dolphins circling the lovely head of the Nereid Arethusa, on the coins of Syracuse; or as the deformed Oriental presentments of them, transformed by deft draughtsmanship into such artistic conventions as of the other Nereid, Amphitrite, and of her father Nereus, and Triton, and the Sirens. These ichthyomorphs, issuing primordially from the banks of the Nile, and the Tigris and Euphrates, were carried by the "go-a-ducking Phœnicians," and later by the "merry Greeks," into every country bordering on the Mediterranean Sea, and under the Italian common name of *sirene*, and *cavalli marini*, are still to be found in use as talismanic trinketry through all the countryside about such old-world places as Palermo and Messina, Naples and Brindisi: while twice in the past forty years I have seen them in those wonderful shop windows of Regent Street, and Piccadilly, and Bond Street—whereof every student of comparative technology may truly say:—

"They are the books, the arts, the academies,
That shew, contain, and nourish all the world!"

If any reader of the *Journal* will compare these *sirene*, or *cavalli marini*, with the representation of the goddess Amphitrite on the mosaic floor, illustrated by Professor Dante Vaglieri in the paper on his archæological researches at Ostia, published in *Nash's Magazine* for last month [December, 1911], it will at once be recognised that the continuity of Greek art, at least in its "motives" and craftsmanship, is as marked among the peasantry of Southern Italy, as is that of Hindu art among the agriculturists of Southern India; and owing very much to analagous physiographical, and geographical and commercial, and political, and religious causes. But India alone still holds the living secrets of the hiero-typology of her art—Hindu art—and of the full significance of the sanctity of the fish; as these were first systematised by the priests and bards of all the historical races, Semites, Hamites, and Aryas, of the Old World, after they had advanced out of savagery [and totemism], into barbarism, toward joyous semi-civilisation [and poetical polytheism]: and for my own part I would rather ever remain a semi-civilised Pagan:—

"So might I standing on this pleasant lea,
Have glimpses that would make me less forlorn:
Have sight of Proteus rising from the sea,
Or hear old Triton blow his wreathed horn."

And as for the sunny "Fountains" of Venus [Aphrodite], great Apollo, Jupiter [Zeus], and Juno [Here], of which Pliny writes, the likes of them, reflecting the ever dazzling sun, flash everywhere like mirrors, over the whole far and widespread plains of India—India of the Hindus: and in Islam itself, the fishgarths before the mosque at Tripolis [Syrian], and the mosque at Edessa [Syrian], are the self-same "Fountains" frequented in the ancientmost days of Anterior Asia by the idolatrous Phœnicians. Among the photographs of the majestic Coronation Durbar at Delhi, published during the current month in the illustrated newspapers of London, one of the most impressive was of the serene and stately *Jama Masjid*, or Mosque, of that right imperial city, with the large square "tank" before it, filling the foreground; and, by a happy coincidence, in *The Wide World* for this month [January, 1912] Mr. J. H. Bell, British Consul at Shiraz, in his paper, entitled "Across Persia and Europe on Pony-back," reproduces, on page 387, a photograph of the shrine at Qumisheh, near Ispahan, with its tank of sacred fish before it. At leisure moments, learned Muslims will playfully feign, or possibly they accept it seriously, that "Jonah's Whale" [Atargatis], is at times to be seen, as in vision, basking in these tanks. Anyhow, Jonah is their Zu'n-Nun, "He of the Whale" [compare "Joshua, the Son of Nun," *i.e.* "Fish," or (Sea) "Serpent," "Oannes"]; and "Jonah's Whale," with the Ox on which Moses rode, and the Ass on which Balaam sat, and the Ass on which the Queen of Sheba rode when she visited King Solomon, and the Ass on which our Saviour rode into Jerusalem, are among the ten or twelve animals that, in the belief of all Muslims, are admitted into Heaven. The very name of the letter N, in Hebrew, Arabic, Greek, English, etc., is said, by Al Baizwai, to be derived from the name of "Jonah's Whale," that is Nun, which refers ultimately to Hea [Atargatis, etc.], and the abyss of waters out of which Oannes arose, somewhere about the vague site of "the Garden of Eden," and there laid the fast-bonded foundations of

Hosted by Google

Mesopotamian industrial, artistic, literary, and religious culture. It seems indeed as if there could be nothing of this world—of the universe—that ever was, or is, or will be, that is not inextricably commingled with everything else, past, present, and future.

Having written so far, I have received a letter insisting on the anagramatic origin of the Christian Fish symbol, and protesting against its identification with "any heathen type." There can, however, be no gainsaying of this historical fact, and it is but one of many instances [see Count Goblet D'Alviella's "Migration of Symbols," edited, with an Introduction by myself: Constable] enforcing the truth so clearly and pithily expressed by St. Thomas Aquinas, in his great Hymn, "Pange lingua," in the verse beginning "Tantum ergo":—

> "Et antiquum documentum
> Nova cedit ritui":—

a hymn which, for spiritual insight, fervent feeling, and the music of its movement is unapproachable within the whole range of Latin Hymnology, unless only by Gladstone's devoutly impassioned translation of "Rock of Ages."

George Birdwood.

GENERAL NOTES.

Machinery for India.—Mr. Frederick Noel-Paton, who is the Director-General of Commercial Intelligence, India, sends the *Journal* a leaflet, in which he points out that India is now the largest single purchaser of machinery from England, but that the business might be largely extended if there was better co-operation between British makers of machinery. Many engineers in England make only part of the appliances required in a given industry. In Europe this matters little, for it is easy to find makers of complementary plant and consult them with a view to completing the requisite estimate. It is different in India. British firms send out travellers, who often fail to get orders because they can only quote for one part of the plant required, and Mr. Noel-Paton urges that through one channel or another full information should be given. In most cases the manufacturer knows what other appliances are required and what their power or capacity should be. "He knows where a suitable engine could be obtained and where—say—suitable crushers or centrifugals could be bought to complete the equipment. In such cases it would be sufficient if he dropped a line to the makers of the complementary plant, saying that a certain official wanted information about a plant for such-and-such an industry, stating that the writer was sending drawings and approximate quotation, and asking that his correspondent should forward similar information about such-and-such complementary appliances of corresponding capacity." In some foreign countries organisation and co-operation among manufacturers has been carried further than in England, and co-ordination between officials and manufacturers is more highly developed.

Agricultural Implement Trade of France.—During 1910, France imported 35,000 tons of agricultural machinery and implements to the value of 45½ million francs (£18,200,000), as compared with 37,000 tons and 48 million francs (£19,200,000) of the previous year. The greater part of this machinery came from the United States, Canada, Great Britain, Germany, and Belgium. The exports, on the other hand, were much less, being 7,400 tons, to the value of 48 million francs (£19,200,000) only. The principal customers for this class of machinery are: Algeria, Tunis, Italy, Switzerland, Spain, Turkey, Chili, and the Argentine Republic.

Consumption of Horse-flesh in Paris.—The consumption of horse-flesh in Paris appears to have increased rapidly from 1897 to 1907, when it reached its maximum; since then it has slowly decreased.

		Kilograms.
1897–1901	the average annual consumption was	5,513,000
1902–1906	" "	10,743,000
1907		14,893,000
1908		14,495,000
1909		14,184,000
1910		13,704,000

Of this last amount, equal to 13,496 tons, 12,197 kilograms were furnished by animals slaughtered in Paris and 1,507,000 kilograms were imported from other places. The total number of animals slaughtered last year at the abattoir for horses in Paris was 49,403, being 48,070 horses, 870 asses, and 463 mules. The average yield of meat per head was 246 kilograms (=542½ lbs.).

Production of Iron Ore in Spain.—Although Spain is a great producer of iron ore, the industry seems to be stationary, the output in 1909 being about the same as in 1899, while the other leading producers have been increasing their output by rapid strides. The failure of Spain to keep pace with the other nations in iron ore production is largely due to the growing scarcity of ore in the Biscayan iron zone. In 1909, in the province of Biscay, 3,870,000 tons of ore were mined, of which over three millions were exported. The provinces of Guipuzcoa and Navarre export yearly from 20,000 to 30,000 tons of ore by rail to France through the station of Irun, and about 75,000 tons by water to the United Kingdom and Germany from the port of Pasages. From the province of Santander 800,000 tons are exported annually. Further to the west, along the northern coast, are the ports of Rivadesella San Esteban, Ribadeo, Vivero, and Corunna, whose exports amount

Hosted by Google

annually to 400,000 tons of phosphoric ores. Practically all the ore from southern Spain, 3,500,000 tons, is non-phosphoric, and thus adaptable for the manufacture of Bessemer steel. The total production of iron ore in Spain in 1909 was 9,384,634 tons.

SERICULTURE IN NORMANDY.—During the last few years silkworm rearing has been revived in Normandy, where it at one time was carried on to some extent. Since 1844 until recently the industry had almost entirely disappeared from the country. A circular has lately been issued by a committee of sericulturists drawing the attention of landowners and farmers to the advantages which might be derived from the planting and cultivation of the white mulberry tree as well as from the production of silk.

SALE OF GRAPES AT FONTAINEBLEAU.—The sale by auction of the grapes from the celebrated vinery of the "Treille du Roi" at Fontainebleau realised 3,374 francs (£135). The total weight of the crop, which was of a very fine quality, amounted to 1,475 kilograms (3,252 lbs.). The grapes, which were sold in fifty-nine lots of 25 kilograms (55 lbs.) each, fetched on the average 2·29 francs per kilogram (about 10½*d.* per lb.). This espalier, which measures 1,350 metres (1,476 yards) in length and 2½ metres in height (8 feet), was planted in 1531 by order of François I., King of France, and here originated the famous *chasselas* of Fontaineblean. The soil is deep, of a sandy nature, and the vines have an easterly and south-easterly aspect.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock:—

JANUARY 24.—WILLIAM J. GEE, "Hydraulic Separating and Grading." ROBERT KAYE GRAY, M.Inst.C.E., will preside.

JANUARY 31. — PROFESSOR G. W. OSBORN HOWE, M.Sc., M.I.E.E., "Recent Progress in Radio-Telegraphy." SIR WILLIAM H. WHITE, K.C.B., F.R.S., will preside.

FEBRUARY 7.—LEONARD HILL, M.B., F.R.S., and MARTIN FLACK, M.A., M.B., B.Ch., "The Influence of Ozone in Ventilation."

FEBRUARY 14.—CECIL THOMAS, "Gem Engraving." SIR ARTHUR JOHN EVANS, D.Litt., LL.D., F.R.S., will preside.

FEBRUARY 21.—FRANK WARNER, "Silk." SIR GEORGE BIRDWOOD, K.C.I.E., C.S.I., M.D., LL.D., will preside.

FEBRUARY 28.—H. A. ROBERTS, M.A., "The Relations of Science to Commerce and Industry." PRINCIPAL SIR HENRY A. MIERS, M.A., D.Sc., F.R.S., will preside.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

FEBRUARY 8. — COLONEL SIR THOMAS H. HOLDICH, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc., "The North-East Frontier of India."

MARCH 14.—E. A. GAIT, I.C.S., C.I.E., Census Commissioner for India, "The Indian Census of 1911."

APRIL 25.—WALTER SAISE, D.Sc., M.Inst.C.E., Hon. Member Institute of Mining and Geology, India, A.R.S.M., V.D., "The Coal Industry and Colliery Population of Bengal."

MAY 16. – NEVILLE PRIESTLEY, Managing Director, South Indian Railway, "Indian Railways."

COLONIAL SECTION.

Tuesday afternoons, at 4.30 o'clock:—

JANUARY 30.—W. A. LEGG, M.Inst.C.E., late Supervising Engineer, Irrigation Department, Cape Colony, "Irrigation in South Africa." The HON. SIR RICHARD SOLOMON, G.C.M.G., K.C.B., K.C.V.O., K.C., High Commissioner for the Union of South Africa, will preside.

MAY 7.—ALAN BURGOYNE, M.P., "Colonial Vine Culture."

MAY 21.—THE HON. J. G. JENKINS, "Australian Railways."

CANTOR LECTURES.

Monday evenings, at 8 o'clock:—

VAUGHAN CORNISH, D.Sc., F.G.S., F.C.S., "Ocean Waves, Sea-Beaches, and Sandbanks." Two Lectures.

Syllabus.

LECTURE I.—JANUARY 22.—The size and speed of ocean waves—The height of waves in lakes, seas, and rivers—The length of waves in lakes, seas, and rivers—The steepness of waves, and strains upon ships—The periodic time of waves, and the rolling of ships—The speed of waves and its relation to velocity of wind—The height of waves and its relation to velocity of wind—The time required to develop large waves, and the duration of storms—The length and speed of the swell observed after storms—The probable height of the swell during storms—The relation between the dimensions and path of a cyclonic depression and the nature of the winds produced—The depth in which waves break, and its relation to defence works.

LECTURE II.—JANUARY 29. — The action of waves and tidal currents on sea-beaches and sandbanks—The proper action of waves to drive

Hosted by Google

sand and shingle shoreward—The proper action of waves to drive mud seaward—Special conditions under which the action on sand is reversed—The proper action of the tide to drive shingle in the direction of the flood—The normal removal of shingle from promontories and its accumulation in bays—The exceptional accumulation of shingle in salient positions, *e.g.*, at Dungeness—Groynes—The reason of the graded arrangement of shingle on the Chesil beach—The formation of a sandbank on the up-channel side of a promontory—Sandbanks in estuaries and their arrangement by tidal currents—Their rippled surface as a means of mapping these currents—Their influence on the formation of tidal bores—The struggle between land water and tidal water to arrange the sandbanks in the Severn—The variability of the Severn Bore as determined by these factors—The circumstances which determine the starting point of the Severn Bore.

LOUDON M. DOUGLAS, F.R.S.E., "The Meat Industry." Three Lectures.

February 5, 12, 19.

LUTHER HOOPER, "The Loom and Spindle: Past, Present, and Future." Three Lectures.

February 26, March 4, 11.

NOEL HEATON, B.Sc., F.C.S., "Materials and Methods of Decorative Painting." Three Lectures.

March 18, 25, April 1.

HOWARD LECTURES.

Monday evenings, at 8 o'clock:—

CAPTAIN H. R. SANKEY, R.E., M.Inst.C.E., "Heavy Oil Engines." Four Lectures.

April 29, May 6, 13, 20.

Dates to be hereafter announced:—

F. MARTIN DUNCAN, "The Work of the Marine Biological Association."

JOHN NISBET, D.Oec., late Conservator of Forests, Burma, "The World's Decreasing Timber Supplies."

CHARLES C. ALLOM, "The Development of Artistic Skill in the Applied Arts."

ERNEST KILBURN SCOTT, Assoc.M.Inst.C.E., M.I.E.E., "The Manufacture of Nitrates from the Atmosphere."

CHARLES BRIGHT, F.R.S.E., M.Inst.C.E., M.I.E.E., "The Administration of Imperial Telegraphs."

HAROLD COX, "The Interdependence of Morals and Economics."

E. D. MOREL, "British Rule in Nigeria."

GORDON CRAIG, "Art of the Theatre." MISS ELLEN TERRY will preside.

THEODORE E. SALVESEN, "The Whaling Industry of To-day."

PROFESSOR ERNEST A. GARDNER, M.A., "Greek Sculpture."

GEORGE FLETCHER, "Technical Education in Ireland."

MEETINGS FOR THE ENSUING WEEK.

MONDAY, JANUARY 22...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Dr. Vaughan Cornish, "Ocean Waves, Sea-Beaches and Sandbanks." (Lecture I.)

Sanitary Engineers, Caxton Hall, Westminster, S.W., 8 p.m. Mr. L. W. Chubb, "Smoke Abatement."

Aeronautical, at the United Service Institution, Whitehall, S.W., 8.30 p.m. Dr. E. H. Hankin, "Bird Flight."

Surveyors, 12, Great George-street, S.W., 8 p.m. Mr. J. C. Rogers, "An Evening in the Institution Library."

British Architects, 9, Conduit-street, W., 8 p.m. Sir Alfred East, "Colour Decoration."

Victoria Institute, 1, Adelphi-terrace House, W.C., 4.30 p.m. Mr. E. W. Maunder, "The Conditions of Habitability of a Planet, with special reference to the Planet Mars."

London Institution, Finsbury-circus, E.C., 5 p.m. Mr. L. Binyon, "Chinese Art."

TUESDAY, JANUARY 23...Royal Institution, Albemarle-street, W., 3 p.m. Professor W. Bateson, "The Study of Genetics." (Lecture II.)

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Discussion on following papers: Mr. Somers Howe Ellis, "Reinforced-Concrete Wharves and Warehouses at Lower Pootung, Shanghai." Mr. W. C. Popplewell, "The Direct Experimental Determination of the Stresses in the Steel and in the Concrete of Reinforced-Concrete Columns." Mr. W. H. Burr, "Composite Columns of Concrete aud Steel." Mr. Richard John Durley, "The Central Heating- and Power-Plant of McGill University, Montreal."

Colonial, Whitehall Rooms, Whitehall-place, S.W., 4 p.m. Dr. T. Miller Maguire, "The New Pacific."

WEDNESDAY, JANUARY 24...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. William J. Gee, "A New Process of Hydraulic Separating and Grading."

Geological, Burlington House, W., 8 p.m.

Economics, London School of, Clare-market, W.C., 5 p.m. Mr. Ben Morgan, "The Trade, Industry, and Finance of the British Empire."

United Service Institution, Whitehall, S.W., 3 p.m. Mr. G. Renwick, "Our Food Supplies in Time of War."

Royal Society of Literature, 20, Hanover-square, W., 5 p.m. Mr. Howard Candler, "Lucian and his Times: the Underflow of Christianity."

THURSDAY, JANUARY 25...London Institution, Finsbury-circus, E.C., 6 p.m. Dr. Vaughan Cornish, "Waves of the Sea."

Royal Institution, Albemarle-street, W., 3 p.m. Professor A. Bickerton, "The New Astronomy." (Lecture II.)

Camera Club, 17, John-street, Adelphi, W.C., 8 30 p.m. Mr. A. Keighley, "Pictures of Italy."

Electrical Engineers, Victoria-embankment, W.C., 8 p.m. Messrs. Miles Walker and H. D. Symons, "The Heat Paths in Electrical Machinery."

FRIDAY, JANUARY 26...Royal Institution, Albemarle-street, W., 9 p.m. Professor B. Hopkinson, "The Pressure of a Blow."

Physical, Imperial College of Science, South Kensington, S.W., 5 p.m.

SATURDAY, JANUARY 27...Royal Institution, Albemarle-street, W., 3 p.m. Rev. John Roscoe, "The Banyoro; a Pastoral People of Uganda." (Lecture II

Hosted by Google

Journal of the Royal Society of Arts.

No. 3,088. VOL. LX.

FRIDAY, JANUARY 26, 1912.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, JANUARY 29th, 8 p.m. (Cantor Lecture.) VAUGHAN CORNISH, D.Sc., F.G.S., F.C.S., "Ocean Waves, Sea-Beaches, and Sandbanks." (Lecture II.)

TUESDAY, JANUARY 30th, 4.30 p.m. (Colonial Section.) W. A. LEGG, M.Inst.C.E., late Supervising Engineer, Irrigation Department, Cape Colony, "Irrigation in South Africa." The HON. SIR RICHARD SOLOMON, G.C.M.G., K.C.B., K.C.V.O., K.C., High Commissioner for the Union of South Africa, will preside.

WEDNESDAY, JANUARY 31st, 8 p.m. (Ordinary Meeting.) PROFESSOR G. W. OSBORN HOWE, M.Sc., M.I.E.E., "Recent Progress in Radio-Telegraphy." SIR WILLIAM H. WHITE, K.C.B., F.R.S., will preside.

Further details of the Society's meetings will be found at the end of this number.

CANTOR LECTURE.

On Monday evening, January 22nd, MR. VAUGHAN CORNISH, D.Sc., F.G.S., F.C.S., delivered the first lecture of his course on "Ocean Waves, Sea-Beaches, and Sandbanks."

The lectures will be published in the *Journal* during the summer recess.

LIST OF MEMBERS.

The new edition of the List of Members of the Society is now ready, and can be obtained by Members on application to the Secretary.

COVERS FOR JOURNALS.

For the convenience of Members wishing to bind their volumes of the *Journal*, cloth covers will be supplied, post free, for 1*s.* 6*d.* each, on application to the Secretary.

THE ROYAL SOCIETY OF ARTS.*

By SIR HENRY TRUEMAN WOOD, M.A.,
Secretary of the Society.

VI.—THE PREMIUMS.
(1754–1851.)

Concluded.

Dollond's invention of the achromatic telescope in 1758 (for even if he was anticipated by Moor Hall, Dollond was an original inventor) rendered necessary the production of glass, especially flint glass, of great purity, perfectly homogeneous and free from striæ. Not only was improvement in the quality of the glass required, but large discs were wanted for astronomical refractors. With this object the Society offered prizes for optical glass in 1768. Two such prizes were proposed—one of £60 for a sample of optical glass, not less than 20 lbs. in weight, "fit for those purposes for which flint glass is used in achromatic telescopes," and a second of £20, for glass "suitable for the general purposes of opticians." The minutes of the committee at which the proposal was discussed do not give any further particulars, nor has any record been found to show with whom the proposal originated. It is possible that the committee hoped to obtain glasses which in combination would prove achromatic for all the colours in different parts of the spectrum, and so to get rid of the "secondary spectrum" or "residual dispersion," which can never be entirely abolished by the use of two kinds of glass only, though the Jena factory has recently produced glasses which go near the attainment of this end. It is also evident, from the stipulated weight of the specimen, that the committee had in view the production of larger discs than could at the time be manufactured. At all events, the committee wisely drafted their proposal in very general terms, so as to cover any possible improvements in the manufacture.

* The previous articles of the series appeared in the *Journals* of June 9th and 16th, September 22nd and 29th, November 3rd, 1911, and January 12th and 19th, 1912.

Hosted by Google

Two prizes were awarded—£30 to Abraham Pelling, in 1770, and £40 to Richard Russell, in 1771—but no practical result followed, and the offer of prizes was not continued after 1779.

It was indeed many years before the need was supplied. The French Academy also offered prizes for perfect discs of optical glass, but without any better success than the Society of Arts. The first to produce such discs was Pierre Louis Guimand, a Swiss watchmaker, about 1790. He was afterwards (1805) associated with Fraunhofer, and on his discoveries are based all the great modern improvements in the production of large discs for refracting telescopes. For any great improvement in the character of the glass itself we have had to wait till our own times, since it is only within the last twenty years that the Jena laboratory has furnished the makers of optical instruments with glasses in which high refractive power is combined with low dispersion, and high dispersive power with lower refractivity.

Henry Baker, the microscopist, was one of the founders of the Society, but this does not seem to have led him to propose any premiums for improvements in the microscope. Nor, indeed, had any such offers been made, could they have had much practical result, since it was not until the achromatic object-glass had been perfected that the modern microscope came into existence. Fraunhofer seems to have been the first to make an achromatic objective of any practical use (about 1816), and this was very imperfect, for five years later (1821) M. Biot expressed the opinion that "opticians regarded as impossible the construction of a good achromatic microscope."* Dr. Wollaston also thought that "the compound microscope would never rival the single." However, in 1824, satisfactory objectives were independently produced by Chevalier, in Paris, and by Tulley, in London, and the development of the microscope went on apace. The use of high powers necessitated the provision of rigid stands, and gradually led to the invention of the various mechanical devices for accurate focussing, and for imparting minute movements to the object, as well as all the other details of construction, which have brought the instrument to its present perfection. In the third, fourth and fifth decades of the nineteenth century, prizes for various improvements in the microscope were awarded to Varley (1831), Powell (1835 and 1841), Goadby (1835), and Ross (1837). The *Transactions* about the same time contain other communications on the subject. Hogg, in his book above referred to, attributes the Society's action to the influence of Mr. Edward Solly, who, he says, "has been the means of making its *Transactions*, since 1831, the vehicle through which nearly all the improvements in the construction of telescopes and microscopes have been made known to the world."*

* "The Microscope," Jabez Hogg (1855), p. 8.

In 1782, a gold medal was offered for "a cheap and portable transit instrument which may easily be converted into a zenith sector, capable of being accurately and expeditiously adjusted for the purpose of finding the latitudes and longitudes of places." This prize was continued till 1819, but without any result. The transit instrument was invented in 1690 by Olaus Römer, the great Danish astronomer, who was the first to measure the velocity of light by observing the eclipses of Jupiter's satellites. The first transit instrument was set up at Greenwich in 1721. It is not very obvious why this prize should have been offered, except that the great improvements in accurate timekeepers, resulting from the work of Harrison, Arnold, and the other skilful chronometer-makers of the time, rendered possible the use of more accurate astronomical instruments, and thus created a demand for them.

In 1774, a gold medal was offered for an invariable standard of weights and measures, and it was pointed out in the notice of the offer that previous suggestions for the determination of a standard by means of the pendulum had not been successful. The first of these suggestions was made by Picard, in 1671, who proposed that a pendulum beating seconds should be employed, and that one-third of its length should be adopted as the standard foot. Nevertheless, the only two candidates who received any awards both proposed to use the pendulum, and both submitted devices which could only give results of moderately approximate accuracy. One of them, Hatton, a watchmaker, who received thirty guineas in 1779, speaks of his apparatus as correct to the twentieth of an inch, though he proposes to employ an adjusting screw to ensure even greater accuracy! Fifteen years later, in 1794, Dr. More, the secretary, submitted a communication to the Society,† in which he very sensibly deprecates a reference to natural constants for the construction of a standard, and proposes the accurate copying of the then existing pound, preserved at the

* *Op. cit.*, p. 11.

Hosted by Google

Exchequer. It seems likely that More was led to publish his paper by the attempts then being made by the French National Assembly to fix on a theoretical standard. In 1790 they passed a decree adopting a system of measures based on the seconds pendulum, but in the following year they abandoned the pendulum, and decided to base their standards on a quadrant of the meridian. When the Republic was proclaimed this proposal was confirmed, and the one ten-millionth part of the arc of the meridian from the Pole to the Equator, was, as is well known, declared to be the metre or standard of length for France.

Dr. More really anticipated the course of our own legislation on weights and measures, which has simply ordained the accurate copying of certain ancient examples, and has declared that these copies are the actual standard weights and measures of the country. Practically the French Government have had to do the same thing, for the metre is not a fractional part of the earth's meridian, but the length of a certain platinum bar, preserved in Paris, just as our yard is the length of a certain bar (or rather the distance being certain marks on that bar) preserved in London.

The premium was only continued for a very few years. It is exceptional, inasmuch as it was open to "persons residing in any country whatever." Had the prize been continued for another 120 years or so, it would therefore have been available for the very beautiful suggestion, made about seventeen years ago by Professor A. A. Michelsen, that the length of the metre might be stated in terms of the wave-lengths of red light.*

In 1777, a gold medal was offered for a method of measuring "the degrees of sweetness in saccharine substances." This does not seem to have meant a saccharometer, but some means of establishing a standard of sweetness. Nothing came of this offer, which was continued for some time, and then abandoned, nor is it conceivable that such a standard could be set up. It was soon after this, in 1784, that the brewer's saccharometer was first introduced by Richardson. of Hull. It was a form of Martin's hydrometer, which indeed had been used in brewing in 1768. It had a scale adapted for the use of brewers, and was indeed merely a hydrometer which indicated the difference between water and wort, water containing a percentage of saccharine matter. Richardson's calculations are said not to have been quite correct, but sufficiently so for practical purposes.

* "Valeur du mètre en longueurs d'ondes lumineuses." Paris (1894). Chaney's "Weights and Measures" (1897), . 23.

The hydrometer in its modern form was described by Robert Boyle in the *Phil. Trans.*, 1675. It remains the same in principle, but has been improved in details, and has been fitted with weights and various scales to adapt it to liquids of different specific gravities. In 1771, a prize was offered for an instrument to measure the strength of spirit, and in 1781 a silver medal was awarded to Matthew Quin for his hydrometer. In 1790, a second silver medal and twenty guineas were given him for an improved instrument, the principal feature of which was a sliding scale to adapt it to different temperatures. Other awards were made, the latest in 1820, but Quin's appears to have been the most important instrument recognised by the Society.

Two gold medals were at different times awarded to the eminent mechanical engineer, Bryan Donkin; one, in 1810, for his tachometer, and one, in 1819, for his counting machine. Mr. Donkin was for long a Vice-President of the Society and Chairman of its Committee on Mechanics. He was the leading mechanician of his time, and was best known for his share in the completion and construction of Fourdrinier's paper-making machine. It can hardly be doubted but that he would have received some recognition for this also from the Society, if the machine had not been the subject of a patent.

The tachometer was so named by himself, and was intended, in his own words, "for indicating the velocity of machines." According to the description in the *Transactions*,* it was meant to indicate the varying velocity of machines rather than to measure their speed. This it did by means of a rotating cup filled with mercury, to which motion was given from some part of the machine. The spinning of the cup causes the level of the mercury to sink at the centre and to rise at the rim. The variations of level were indicated by the rise and fall of a column of spirit in a glass tube, the lower end of which was immersed in the mercury.

The counter would appear to be the original form of the now well-known device in which a train of wheelwork indicates on a series of dials for units, tens, etc., the revolutions of any spindle. Two arrangements are shown, both working by ratchet-gear, and indicating by clock-hands on a single dial.†

The award in 1825 of a silver medal and thirty guineas to W. Sturgeon, for "Improved Electro-Magnetic Apparatus," is of extreme interest, because the account of his apparatus contributed by Sturgeon to the *Transactions*,* proves him to have been the inventor of the electro-magnet. The whole subject has been very carefully worked out by Professor Silvanus Thompson,† who quotes a letter from Dr. Joule to Mr. Angus Smith, in which that great philosopher says:—"I have sifted Mr. Sturgeon's claims to the utmost. I have examined all the periodicals likely to throw light on the history of electro-magnetism, and find that Mr. Sturgeon is, without doubt, the originator of the electro-magnet, as well as the author of the improved electro-magnetic machine. The electro-magnet described by Mr. Sturgeon in the 'Transactions of the Society of Arts for 1825' is the first piece of apparatus to which the name could with propriety be applied. . . . To Mr. Sturgeon belongs the merit of producing the first electro-magnet constructed of soft iron."

Dr. Joule also states that Sturgeon was "without doubt the constructor of the first rotary electro-magnetic machine," the inventor of the commutator, and the first to use amalgamated zinc plates in batteries.

Professor Thompson reproduces the pictures of Sturgeon's electro-magnets from the *Transactions*, and expresses the regret which all interested in the subject must share, that the actual instruments, given by the inventor to the Society's museum, have not been preserved. He also, in an appendix, gives a very full account of Sturgeon's life and researches. Like so many other inventors, Sturgeon never received in his lifetime either the recognition or the reward he deserved. After his death his discoveries were utilised and developed by his successors, whose increased knowledge enabled them to realise the value of researches which his contemporaries were not sufficiently well-informed to appreciate.

Two years previously, in 1823, an identical award had been made to James Marsh, the chemist, who devised the well-known test for arsenic still associated with his name, and with whom Sturgeon had been for some time associated. In the note appended to Sturgeon's communication to the *Transactions*, attention is drawn to several points in which Sturgeon's apparatus is considered superior to that of Marsh.

† "The Electromagnet," by Silvanus Thompson, F.R.S. (Second Edition, 1892), pp. 2-9, and Appendix A, p. 412.

The award of a gold medal in 1840 to Alfred Smee for his galvanic battery was certainly well deserved. A convenient source of electrical energy was then much wanted, and Smee's cell was a great advance on all its predecessors. It was fairly constant, moderately cheap, of high electro-motive force, free from fumes, and readily put in and out of action without loss or waste.

The negative element was a thin sheet of platinised silver, the platinum being deposited as a fine adherent powder on the surface of the silver, which had previously been slightly roughened. This plate was supported in a light wooden frame between two zinc plates which formed the positive element. The exciting fluid was diluted sulphuric acid.

Smee's battery came into very general use for experimental work, and was for long used and greatly appreciated. A well-known and popular writer on electrical matters said, in 1875, after the battery had been in use for over thirty years, that it was "one of the most valuable gifts ever made to electrical science."*

The now universally used method of obtaining a conducting surface for electro-deposition by means of plumbago was the discovery of Robert Murray, and for it he received a silver medal and ten pounds in 1841. In his paper in the *Transactions*,† he says that Edward Solly was the first to obtain a conducting surface on a non-conducting material by the use of nitrate of silver, and he goes on to describe his own process, which is identical with that now used. In fact, the instructions he gives describe in every detail the present method.

In the later volumes of the *Transactions* are to be found descriptions of a great variety of instruments which received rewards of different value from the Society. Many of these are obsolete, many contain the germs of appliances since improved and perfected, some are now familiar. Drawing instruments, "perspectographs," etc., are numerous. Amongst these may be mentioned the ordinary child's "transparent slate," which now common toy received a gold medal in 1814, as a valuable means of teaching writing. There are several ellipto-graphs (including those devised by Farey, Cubitt, Clement, and Hicks), Ross's first spherometer (1841), with a central axial sliding rod, mounted in a truly-turned supporting ring, afterwards perfected by the substitution for the ring of a frame with three supporting points. Surveying instruments, sextants, and their predecessors,

* J. T. Sprague, "Electricity" (1875), p. 91.

† Vol. LIII. p. 10.

Hosted by Google

quadrants and octants, appear in the lists. Surgical and dental instruments are also fairly numerous. The list is a very long one. As to the value of its contents, only an expert in each class could speak with confidence, but its immense variety, at all events, bears testimony to the catholicity of the Society's objects and operations in the first half of the nineteenth century.

After the application of gas for illuminating purposes by Murdoch in 1792, we find a few prizes offered and awarded for improvements connected with gas-lighting.

In 1797 a prize was offered for a "substitute for tar," but though the offer remained open for many years, it does not seem to have attracted any competitors. This is remarkable, because the production of tar from coal had been known and practised for a considerable period. In 1681 letters patent had been granted to John Joachin Becher and Henry Serle for "a new way of makeing pitch and tarre out of pit coale." These inventors were followed by several others, amongst them the Earl of Dundonald, who had a patent for obtaining tar and other products from coal.

In 1810, B. Cook, of Birmingham, describes a process for the distillation and utilisation of gas-tar, which he said was at the time a waste product, though considerable amounts were made in the production of gas, and the coking of coal.* The tar, Cook stated, was superior to the "common tar" for paying ships' timbers. The more important part of the communication related to a method of distilling the tar, from which a "liquor or volatile oil" (light oil) was obtained, and a "residuum" (pitch) "equal to the best asphaltum." He had varnish made from the pitch and the light oil, and sent in a sample of work treated with the varnish. For this paper, which was certainly among the early practical proposals for the utilisation of the by-products of gas-manufacture, Cook received the very inadequate reward of a silver medal.

Cook, however, had been anticipated by Winsor, whose patent specification of 1804 refers to the production and utilisation of various by-products from gas-making. Still, Cook's paper is full of interest, as he appears to have been an original worker and to have achieved a considerable measure of practical success.

In 1808 a silver medal was given to Samuel Clegg "for his apparatus for making carbonated hydrogen gas from pit coal, and lighting factories therewith." The apparatus included a gas-holder of the form now generally employed, of which Clegg was apparently the inventor. He was apprenticed to Boulton and Watt, and was in business in Manchester as a builder of steam-engines. He was the inventor of the gas-meter, which he patented in 1815, but (probably because it was the subject of a patent) he did not submit it to the Society. In 1819 a gold medal was given to John Malam for improvements on Clegg's original meter.

* *Transactions*, Vol. XXVIII. (1810) p. 73.

It is worth mention that the well-known telescopic gas-lamp, or chandelier, which is in common use up to the present date, was invented by William Caslon, who received a silver medal for it in 1817. The drawings in the *Transactions** show a chandelier identical with the most modern form, with sliding tubes, water-seal and counter-balance weights.

In the year 1802, a gold medal and a grant of fifty guineas were given to Henry Greathead, of South Shields, for the invention of the lifeboat. There seems very little doubt that Greathead was the builder of the first practical lifeboat, but it is uncertain how far the actual invention was due to him. The subject has been very carefully and exhaustively worked out by Sir John Lamb in a paper on the lifeboat, which he read before the Society in 1910.† In 1785, Lionel Lukin, of Long Acre, took out a patent for an "unimmergible boat." Nothing very much seems to have come of Lukin's invention, though in the year that he took out his patent he converted a coble into a safety-boat, which was afterwards employed at Bamburgh, Northumberland, in saving life from shipwreck. Lukin's boat was fitted with a cork gunwale and airtight cases at the end. Another inventor was William Wouldhave, of South Shields.

In April, 1789, the Brethren of the Newcastle Trinity House had before them a proposal to station a boat permanently at the mouth of the Tyne, for the saving of shipwrecked persons. A committee was appointed to consider suggestions for the construction of a suitable boat, and to this committee both Wouldhave and Greathead submitted models. Neither was adopted, but Greathead, who was a skilled boat-builder, was instructed to build a boat, which he seems to have done, partly carrying out his own ideas and partly those of some of the members of the committee.

The various claims of the three inventors have long been the subject of discussion, and are never likely to be settled. But it is clear that Greathead's was the first practical lifeboat, and

* Vol. XXXV. p. 162.
† *Journal*, Vol. LVIII. p. 354.

Hosted by Google

the credit of its construction may be allotted to him. Besides the awards from the Society, Greathead received a grant of £1,200 from Parliament, 100 guineas each from the Trinity House and from Lloyd's, besides various other rewards.

A little earlier than this, attention had been directed to means of saving life from shipwreck by methods for effecting a communication between stranded ships and the shore. In 1792, the Society had given a "bounty" of fifty guineas to John Bell (then a sergeant, but afterwards a lieutenant, in the Artillery), for a method of throwing a rope from the ship to the shore.* But a great improvement upon this was brought before the Society sixteen years later, when Captain Manby received a gold medal† for his device for establishing communication from the shore to a stranded ship by the use of a mortar by which a line was thrown. The apparatus itself was devised in 1807, and was successfully used in the following year at the wreck of the brig "Elizabeth." It had previously been reported upon favourably by the Board of Ordnance, and before many years were over it was in extensive use all round the coast. After some twelve years' experience, the invention had been used so successfully, and had saved so many lives, that a Committee of the House of Commons recommended a payment to Manby of £2,000. The invention is still widely used in this and in other countries, but for many years past rockets have been substituted for the original mortar.

Other inventions of the same character were also rewarded by the Society about the same time, but none of them have stood the test of experience in the same way as Manby's well-known apparatus.

In 1776, a silver medal was given to Shipley, the originator of the Society, for a lighted buoy for saving life at sea. As the invention does not seem to be either specially valuable or remarkably original, it may, perhaps, be assumed that a certain friendliness of feeling dictated the award, as respect for his memory may have led to the publication of a description of the apparatus in the *Transactions* ‡ a few years after the inventor's death. A similar feeling may justify its mention now.

In the last half of the eighteenth century a great number of county maps were published. Their issue may without much doubt be traced to the offer by the Society of a prize of £100 for the map of any county on the scale of an inch to the mile. In justification of this statement it may be said, that, of the county maps mentioned by Gough in his great work on British topography, published in 1780, as being issued or in hand at that date, nearly all appear to be of a later date than 1762; and the same may be said of a list of such maps, which has been most obligingly placed at the disposal of the writer by Sir H. George Fordham, the great authority on this subject. Speaking of the survey of Yorkshire, which was carried out by Thomas Jefferys, the well-known cartographer, Gough says: "Jefferys undertook this, and other such surveys, in consequence of a premium of £100 offered by the Society of Arts for a county map." Jefferys died in 1771; this may account for his never having received a premium. After his decease the map was purchased and published by Robert Sayer.

This prize of £100* was first offered in 1759, though it was not included in the regular premium list before 1762. To avoid needless competition, a special announcement was made that the Society would accept an offer for the production of each map, and would afterwards pay the premium when the map was completed to its satisfaction. The first offer accepted was for a map of Dorsetshire by Isaac Taylor. This was published in 1765, and is described by Gough as a capital survey of the county, but he adds: "This, though the most particular, is very faulty in the place names." Whether on this account or for other reasons, no award was made to Taylor. There was some correspondence with him, and the last entry is in December, 1765, when the consideration of his map was "postponed." The first actual award was to Benjamin Donn, who in 1765 received £100 for his map of Devonshire. This was engraved by Jefferys.

The offer of prizes was continued in various terms up to 1801, after which it does not appear in the premium list, though awards were made as late as 1809. Smaller amounts than the original sum of £100 were sometimes paid, and in some cases medals were given instead of

* *Transactions*, Vol. X. p. 203; Vol. XXV. p. 135.

† *Ibid.*, Vol. XXVI. p. 209.

‡ Vol. XXV. (1807) p. 94.

* It was, however, but a small contribution to the actual expenditure on the production of such maps, if we are to rely upon the statement contained in Gough's notes on Sussex, in which a projected map of that county on a scale of two inches to a mile, in eight large sheets, is referred to as estimated to cost more than £2,400 for surveying, drawing and engraving, and to take six years in execution, four hundred subscribers at six guineas for the whole map being asked for.

Hosted by Google

money prizes. In all, an amount of £460 was expended, besides four gold medals, three silver medals, and a silver palette. Maps were obtained of the following counties:—

Devonshire (1765)	Hampshire (1793)
Derbyshire (1767)	Sussex (1796)
Northumberland (1773)	Oxfordshire (1797)
Leicestershire (1778)	North Wales (1802)
Somersetshire (1783)	Cardiganshire (1804)
Suffolk (1784)	Shropshire (1809)
Lancashire (1787)	

Many of these are mentioned in Gough.

For the map of Derbyshire P. P. Burdett received £100. This map was said to have been produced under the direction of the Rev. John Prior, of Ashby-de-la-Zouch, who himself received a silver medal and twenty guineas in 1778, for a map of Leicestershire, which was really made by J. Whyman, an assistant of Burdett, and was published in 1777. Burdett also produced maps of Cheshire and Lancashire.

William Faden, who received £50 for a map of Hampshire in 1793, and a gold medal for one of Sussex in 1796, was a well-known map-maker. He afterwards presented to the Society a number of county maps which he had produced.

John Cary (whose name is given as Carey in the list) received a gold medal in 1804 for his map of Cardiganshire. This engraver and map-seller is best known as the publisher of the "New Itinerary," a road-book which ran through eleven editions, 1798 to 1828, but he, and his successors, G. and J. Cary, engraved and published between about 1769 and 1850 a very large number of maps, atlases, and topographical works.*

The map of Northumberland, for which in 1773 Lieutenant Armstrong received fifty guineas, is said to have been a capital map. It was engraved by Kitchin in 1769. Lieutenant (afterwards Captain) Armstrong was a son of an earlier map-maker of repute, Captain Armstrong.

Besides the Society's prize maps, a good many other county maps were issued. The *Transactions* for 1801† gives a list of twenty-six such maps of English counties in the possession of the Society, and some were afterwards added. In all, about fifty seem to have been produced, besides the great series issued by the Greenwoods (1829–34).

In 1802 the Society offered three gold medals for mineralogical maps of England, Ireland, and Scotland. Each map was to be on a scale of not less than ten miles to the inch, "containing an account of the situation of the different mines therein, and describing the kinds of minerals thence produced."

It is not reported that any of these medals were awarded; but the offer had the important result of assisting William Smith to publish his great geological map of England and Wales.*

William Smith is known as the father of British geology. As Canon Bonney says of him, in his life in the "Dictionary of National Biography," "he found the key to stratigraphy—viz., the identification of strata by their fossil contents." Though a well-known and successful canal engineer (he received a medal from the Society in 1805 for draining Prisley Bog), he was a poor man, and had great difficulties in publishing his map. He was assisted by the Society with £50, and his map of England and Wales and part of Scotland—in fifteen sheets, measuring 8 ft. 9 ins. high by 6 ft. 2 ins. wide, and on a scale of five miles to the inch, with geological colouring—was engraved and published by John Cary on August 1st, 1815, with a dedication to Sir Joseph Banks, P.R.S. It was accompanied by a memoir to the map (London, 1815, 4to), also published by Cary, who, in addition to stratigraphical tables issued in 1816 and 1817, published a series of six detailed geological sections across various parts of England (1817–19) and also, between 1819 and 1824, twenty-one out of the full number of the county maps in his large folio atlas ("Cary's New English Atlas," 1809), with Smith's geological colouring and marginal notes on the strata.

In the same year (1802) as that in which the prizes for mineralogical maps were offered, the Society also offered a gold medal for a "Natural History" of any English or Welsh county. This was to be really an account of the natural resources of the county, "so that the public may be enabled to judge what arts or manufactures are most likely to succeed in such county." This information was more effectively provided by the "Statistical Surveys" of the counties, published by the Board of Agriculture. The first of these is dated 1793, so the offer of the Society seems rather superfluous.

In 1803 the Society gave fifty guineas to R. Horwood for his map of London. Some sheets of the map had previously been submitted, in 1791, but the Society declined to

* See "John Cary, Engraver and Map-seller," a paper by Sir H. G. Fordham, read in 1909 (December 6th) to a meeting of the Cambridge Antiquarian Society, and published in pamphlet form. Cambridge, 1910, 8vo.

† Vol. XIX. p. 43.

* An "explanation" of the map and some most interesting "observations" by Smith, are given in the *Transactions*, Vol. XXXIII. (1815) p. 51.

Hosted by Google

make any award to the work in its incomplete state, though they passed a vote of thanks to the author. There had been a number of maps of London published since Ralph Aggas issued what is believed to be the first map of the sort somewhere about 1560. Horwood's map was certainly a considerable advance on any of its predecessors, and more elaborate than any of them. It was one of the few maps of London made from an actual survey, carried out, as he says, by Horwood himself. All the houses are numbered, and it is stated that the publication of Horwood's map led to the general adoption of numbering, which had previously only been applied to a few streets. This statement, however, does not seem to rest on any very good authority. Not a great deal is known about Horwood. He was surveyor to the Phœnix Fire Office. It is said he produced his map for the use of that office, but he makes no reference to this in the letter from him printed in the *Transactions*.*

Although no actual award, beyond the thanks of the Society, was made to Messrs. Perkins & Co. for their description in the *Transactions*† of their process of steel-engraving for bank-notes, it is too interesting to be passed over. This absence of any award is doubtless due to the fact that the process was in use in America and by private English banks. It was afterwards applied to the production of postage stamps, when the introduction of the Penny Post in 1840 caused a demand for a large number of identical stamps.‡ Jacob Perkins, the principal of the firm, was a very ingenious inventor, and received several gold and silver medals from the Society. An American by birth, he passed much of his life in England. He was a pioneer in the use of high-pressure steam, and in this he was followed by his son, Angier March Perkins, and his grandson, Loftus Perkins, the last-named of whom built several of the first high-pressure steam-engines, and suffered the usual fate of those who are in advance of contemporary ideas.

In the "siderographic process," as it was termed, a soft steel roller was rolled to and fro over the surface of an engraved steel plate, until the design was transferred to the roller, which was then hardened, and used to produce other steel or copper plates. From these, impressions could be taken on paper in the usual way. As any number of these duplicate plates could be obtained, it was possible to produce as many identical paper prints as could be required. In the case of bank-notes, it was proposed that several artists of repute should be employed, each to produce a small vignette. All these vignettes were to be transferred to a single plate, on which also engine-turned patterns might be engraved. Thus prints, both artistic and complicated, would be produced, which certainly it would be beyond the power of any forger to copy, before the invention of photography.

From the commencement of the eighteenth century the paper industry had been developing, but it was chiefly concerned with the production of low-class papers. In the finer qualities English manufacturers could not compete with the productions of French and Italian mills.

The "export of paper in 1775 by Whatman seems to mark a turning-point in English paper-making. . . . Between 1754 and 1782 the Society of Arts was endeavouring to promote the manufacture of high-class paper in this country by the award of premiums and medals for the production of paper for copper-plate printing. The manufacture of silk-rag paper and of embossed and marbled paper also engaged its attention." *

As Mr. Rhys Jenkins says, many prizes were offered at different times for paper and paper-making materials, and these were continued for many years after the date he mentions. The first was the prize offered in 1757 for paper for copper-plate printing, and one of the latest that proposed, in 1830, for methods for manufacturing paper equal to China paper. At an early date an earnest attempt was made to obtain materials for paper other than rags, and a prize was offered in 1790 for paper from raw vegetable substances. In the announcement of this it was stated that the Society already possessed specimens of paper made from "thistles, potatoe haum, poplar, hop binds, etc." This offer was continued for thirty years without any addition being made to the list of materials, but it possesses a good deal of interest, because it was an intelligent anticipation of the course of future progress. Now, of course, practically all paper is made from "raw vegetable substances," that is to say, from cellulose which has not already been made up into some textile material. The volume of *Transactions* for 1823–4 (Vol. XLII.) was printed upon paper which, it is stated in a note, was made from "pure flax." The paper is good and is in excellent condition now, which is more than can be said for the paper of many of the volumes.

It was really not until about 1860 that paper materials other than rags were generally used. About that time esparto began to be employed to a considerable extent. In 1856, fifty tons of esparto were imported, and perhaps this may be taken as the beginning of its application to the extensive manufacture of paper.*

It is rather remarkable that so little was done by the Society for printing, in connection with which there are practically no awards of any importance. Perhaps the most interesting entry in this class is that of the gold medal awarded, in 1819, to Aloys Senefelder as the inventor of lithography. The Society was a little behindhand in this award, for the process had been perfected by the inventor in 1798.

The justification for the medal being given at this time was no doubt the fact that in the year 1818 Senefelder published his "Lehrbuch der Steindruckerey," and that it was this book that really drew attention to the new art, though before this date lithography had been applied to artistic purposes. The first dated English lithograph is a reproduction of a pen drawing by Benjamin West, P.R.A. It bears the date 1801, and was published with other similar plates by Fuseli, Barry and others in 1803.†

Senefelder was much gratified with the award, and he sent to the Society, through Mr. Ackerman, one of his lithographic presses. In the same year that Senefelder was thus honoured, a silver medal was awarded to C. Hulmandel "for a lithographic drawing," and in 1829 Joseph Netherclift received £20 "for his improved methods of making lithographic transfers."

In 1793 an application was made to the Society by some of the principal London basketmakers, which stated that their business was almost at a stand for want of osiers, because "great quantities of these twigs had annually been imported from France, and all intercourse with that country being stopped, a sufficient quantity, the growth of England, could not be obtained." As a consequence of this a great number of the workmen had been thrown out of employment. A number of prizes for planting osiers were offered, and the result was very satisfactory. Many landowners started osier plantations, and numerous prizes were awarded, including a gold medal in 1797 to Lord Brownlow, so that in 1806 the Society was able to announce that its object had been accomplished, and a sufficient supply of English osiers provided. The offer of prizes was consequently discontinued.*

It does not appear to be known with any certainty when the straw-plaiting industry was first introduced into England; but it was certainly established at Luton and Dunstable by the middle of the eighteenth century. A little later the Society did a good deal to encourage it. In 1762 and the three following years a number of small premiums were given for "chip hats like the Italian," and at the same time prizes were offered for straw hats like those made at Leghorn; but without any result. In 1805 a gold medal was awarded to William Corston for making straw-plait similar to the Leghorn plait from rye straw grown in Norfolk.† Again, in 1822, a silver medal was given to John Parry for the manufacture of Leghorn plait from straw imported from Italy. In the same year a silver medal was given to Miss Sophia Woodhouse, of Connecticut, U.S.A., for a new material for straw-plait, which turned out to be the *Poa pratensis*. Through the agency of the Society seeds of the grass were imported, and grown here.

William Cobbett thought he saw an opportunity of encouraging a useful industry in England, and printed an account of what had been done in his "Register." An importer of Italian straw then applied to Cobbett to know whether he could not get any of the American straw. The result of this was that Cobbett set to work in his usual energetic manner to see if English grasses might not be used for the same purpose, and he was successful in utilising various native straws and grasses. In appreciation of his efforts, the Society gave him a silver medal. Cobbett not being by any means a popular character at the time, the award did not meet with general approval. Edward Smith, Cobbett's biographer, says that the newspapers announced the award with the heading, "The Society of Arts humbugged at last." The award was of course perfectly well deserved, and apparently the real objection

was to Cobbett's political views, not to the useful work he had promoted. However, the Society continued to encourage the industry, which it hoped might occupy numbers of unemployed, and for three or four years it continued to give a number of small rewards, varying in value from fifteen to two guineas for the manufacture of hats and bonnets made of English straw.*

The manufacture of leather received less encouragement from the Society than might have been expected, considering that the industry had one of its most important seats close to London, in Bermondsey. In the year after its formation (1755) a prize was offered for buff leather, then principally imported. The prize was duly awarded, and the manufacture started, with a certain amount of success. "The Kentish Militia and some other corps had their accoutrements made of it."† It does not, however, appear that the production of such leather was continued.

The story of the introduction of the method of "Dying leather red and yellow as practised in the East for that kind called Turkey Leather" is rather a curious one. Dossie‡ tells us that one Phillippo, "an Asiatic" who was in England, was induced by two members of the Society to "try, on his return to the East, to make himself master of this and some other arts not known here, in order to communicate them, by means of the Society, in case he should come again to England." The Society agreed to pay him £100 if he succeeded, and on his return to this country with the secrets of the process, the money was paid him, with the additional complimentary gift of a gold medal.

The tanning industry was a long established and flourishing one in this country, but it was hampered by protective legislation. Only certain materials, of which oak-bark was the principal, were allowed to be used. This provision was not apparently for the benefit of the tanners, but to secure the use of proper materials, and, perhaps, to encourage the growth of timber. As a matter of fact, not only was the bark of timber trees used, but oaks were grown in coppices, which were cut for the sake of the bark alone. The Act in which this provision was included was held to prevent the use of oak saw-dust, and therefore a method, said to be successful, of utilising this material could not be employed. The Society gave the inventor £100, and protested against the clause in the Act—with what effect is not recorded. Prizes were offered, and a few awarded, for new tanning materials and methods, but the list is not a long one.

A great many inventions for saving life from fire and for extinguishing fires were rewarded by the Society. Among the latter was an invention of Ambrose Godfrey for extinguishing fires, which was brought under the notice of the Society in 1760 by the inventor's son. To test the device, a building was erected in Marylebone Fields. On May 21st, 1761, the building was set on fire, and when it was in full blaze Godfrey's shells were thrown into the house. According to a contemporary description, "their explosion immediately extinguished the fire, and even the smoke soon disappeared." This demonstration was carried out in the presence of the Duke of York, Prince William, afterwards William IV., Prince Henry, afterwards Duke of Gloucester, and a numerous crowd which was kept in order by a guard of 200 men.

There were also a good many fire-escapes. One of these, for which fifty guineas were voted in 1810 to John Davis, is practically identical with the modern fire-escape with its telescopic ladder and carriage. In his description of his apparatus, the inventor says that his attention was drawn to the subject by the death of a woman at Chelmsford, who had fallen off a "parish ladder" when trying to escape from a burning house.

In 1805 a prize was offered for a method of rendering muslin uninflammable without injuring the quality or appearance of the fabric, but though the offer was continued for many years, it met with no response.

The proposal was a very old one. As early as 1735 a patent was granted to Obadiah Wilde, who added a mixture of alum, borax and vitriol to paper pulp, with the view of producing incombustible paper. In the early part of the nineteenth century the subject attracted the attention of many chemists, amongst others of Gay-Lussac, who in 1830 proposed the treatment of fabrics with the carbonates of potash and soda. Fuchs suggested water-glass. In 1859 an elaborate paper was read to the British Association by Versmann and Oppenheim, who gave a full account of their own researches. An abstract of this paper, and an account of the valuable investigations by Sir Frederick

* A very full account of the development of the straw-plait trade is to be found in a paper read by Mr. A. J. Tansley on December 19th, 1860, and printed in the *Journal* of the 21st of that month (Vol. IX. p. 69). In the discussion, the secretary (Mr. Peter Le Neve Foster) gave a very full list of the awards made by the Society from 1805 down to 1825.

Abel carried on from 1855 to 1881, will be found in a report of a committee of the Society on fire prevention, published in 1883.* This gives a fairly complete history of the various attempts to render fabrics and other materials uninflammable, down to the date of its issue.

The supply of fish to London had always been a difficulty, and though many attempts had been made to bring fish by land, none of them had succeeded.† In 1761 a scheme for the supply of the markets of London and Westminster—a new fish-market had been started in Broadway, Westminster, in 1752—with fish brought up from the coast by land was laid before the Society by John Blake. The Society took up the proposal very warmly, and agreed to give Blake £1,500 for the purpose of carrying it out. Eventually no less than £3,500 was spent on this scheme. The proposal was taken up with a great deal of enthusiasm. According to a statement in the first volume of the *Transactions*, Parliament also made Blake a grant of £2,000, and by the energy of the Society an Act of Parliament was obtained by which the tolls on fish carriages were reduced, and other facilities granted for breaking down the monopoly in the London fish supply which then existed.

At first the Society were very much gratified with the result of their efforts, and they awarded Blake a gold medal with the inscription, "Fish Monopoly Restrained." But the practical results of the procedure do not seem to have been very satisfactory, for in the article above mentioned,‡ it is stated that the "plan has not in every degree answered the sanguine expectations of the Society." Still, it is stated that a good deal of fish had been brought up by land, and the fish-supply of London increased. It also appears that the Society were not quite satisfied with Blake himself, because there is evidence in the minutes of disputes having arisen about his accounts.

A later attempt to develop British fisheries was more successful. In 1805 a reward was offered for "curing herrings by the Dutch method." For some years this does not seem to have had much result, but in 1819 and 1820 two rewards of fifty guineas and £50 respectively were paid to J. F. Denovan, of Leith, for his success in the "curing of British herrings," and for introducing them into the market. Two communications in the *Transactions** give an interesting account of the way in which, after many unsuccessful attempts to get hold of the secrets of the business in Holland, he secured the help of six experienced Dutch fish-curers, and with their help started to catch and cure herrings on the west coast of Scotland. After a good deal of trouble and various misadventures, he was quite successful in his enterprise, and succeeded in sending to Edinburgh and London cargoes of herrings equal to the best Dutch. The method employed, then as now, is merely, after gutting and cleaning the fish, to pack them in barrels with salt or brine. Many other awards followed, and this was the beginning of the Scotch cured herring trade, which developed into an important business, and has, of quite recent years, spread to the East Anglian fishing ports. At the present time it is a thriving industry at Lowestoft.

In 1783 the Society proposed to deal with the question of general education, and the following announcement was made in the first volume of the *Transactions*†:—"The Society, desirous to improve the present mode of education, hereby offer the gold medal to the master of any academy or school for boys situated within or not more than thirty miles distant from London, who shall within three years from the date of this advertisement teach the greatest number of scholars, not less than four, to write and to speak Latin in common conversation correctly and fluently. Also the gold medal for teaching in like manner each of the following languages, viz., the German, the Spanish, and the Italian, being commercial languages, not usually taught at schools in England."

In December, 1786, Dr. Egan, the master of the Royal Park Academy, Greenwich, brought up five of his pupils, whose ages were between eleven and fifteen, and they, after being duly examined by the committee, were each awarded a silver medal, the gold medal being given to Dr. Egan.

In its earlier years the Society offered various prizes of a miscellaneous sort, prizes which may be taken as evidence of the catholic nature of its objects from its very foundation. Such, for instance, was the gold medal for a treatise on the "Arts of Peace" offered in 1759, a time when the arts of peace must have been less in men's minds than those of war, since the country was engaged in fighting in Europe, Asia, and America.

Among social and economical questions the question of female employment crops up again and again from 1768 onwards. Sometimes a reward is offered to those who employ the greatest number of women and girls in specified industries. Then more general offers are made—requests for suggestions, and so on. The general question of want of employment also comes up, and proposals are requested for providing employment for the poor, and for workhouse paupers especially.

It might be thought that the question of housing the agricultural labourer is a fairly modern one. It is certainly an object of discussion at the present moment. In 1799 the Society offered a gold medal to the landowner who should build in that year the greatest number of cottages with an allotment of two acres apiece, and another gold medal to the landlord who should apportion allotments of two acres to existing cottages on his estate. The offer does not appear to have attracted any response, and, after a few years, it was discontinued.

PROCEEDINGS OF THE SOCIETY.

SEVENTH ORDINARY MEETING.

Wednesday, January 24th, 1912; ROBERT KAYE GRAY, M.Inst.C.E., Member of the Council of the Society, in the chair.

The following candidates were proposed for election as members of the Society:—

Buchanan, James, J.P., Lavington Park, Petworth, Sussex.

Jones, Harry, 32, Acfold-road, Fulham, S.W.

The following candidates were balloted for and duly elected members of the Society:—

Burns-Begg, Colonel Robert, The Residency, Salisbury, South Rhodesia, South Africa.

Cochrane, His Honour Judge Andrew January, Maysville, Kentucky, U.S.A.

Hart, William Edward, M.A., J.P., Kilderry, Londonderry, Ireland.

Heming, Arthur, 8, James-street North, Hamilton, Ontario, Canada.

McKerrow, George, M.D., 7, Barns-street, Ayr, Scotland.

Morgan, G. S. Delmar, B.A., Kuala Lumpur, Selangor, Federated Malay States, and Thatched House Club, St. James's-street, S.W.

Tubby, Alfred H., M.B., M.S., F.R.C.S., 68, Harley-street, W.

Veitch, Henry Newton, 22, Old Burlington-street, W.

The paper read was—

A NEW PROCESS FOR THE SEPARATION AND GRADING OF SOLIDS SUSPENDED IN LIQUIDS.

By WILLIAM J. GEE.

An important natural law, which governs a large number of industrial processes, is that which accounts for the property possessed by water and other liquids of holding in suspension particles or grains of insoluble solid matter, when stirred up with them, and afterwards depositing the solid material when agitation has ceased.

If we examine this phenomenon closely, we shall find that, where there are particles of different size or mass suspended in a liquid, these deposit in sequence, the heaviest or coarsest first, and the finest or lightest last. The time taken for the solid particles to settle out of the liquid may vary from seconds, in the case of sand or coarse grit, to days, or weeks, as in the case of very finely-divided material.

This phenomenon is illustrated in Fig. 1, which shows a section of a vessel where solid matter suspended in a liquid has been allowed to settle. *A* is the water from which the solid matter has been deposited, *B* and *C* indicate the fine and coarse particles respectively, ranging in successive strata, in the order of their settling, from the coarsest at the bottom to the finest at the top. It would not be impossible, although somewhat difficult, to scrape off successive layers from this deposit, and thus remove the deposited material in two or more classes or grades of fineness.

It is found also that solids are deposited from liquids which flow very slowly. In this case, the heaviest and coarsest settle first, as before stated, but the finer and lighter particles are carried further along before settling out. This is illustrated in Fig. 2, where a current of water is shown flowing through a long trough, entering at *A*, charged with solid matter, and, after flowing slowly along the trough, running off at *B*. By adjusting the rate at which the water flows, it would be possible to arrange that all the solid matter would be deposited in the trough, and the water would run off perfectly clear. If we examine the material deposited in the trough, we shall find that it is graded from one end to the other, ranging from the coarsest at *C* to the finest at *D*. This method has the very great advantage over that shown in Fig. 1, that the grades are deposited side by side instead of one

Hosted by Google

on top of the other, and the removal of the material in the desired grades or classes is much facilitated.

It will, of course, be obvious that the movement of the water must, to some extent, retard the settlement of the solid particles, especially the lighter ones, and that, therefore, the deposition of the suspended matter from the water takes longer when the water is moving than it does when the water is quiescent. In practice, it is usual, in the many industries where this settling-out process is employed, to combine both methods. The water is allowed to flow along a slightly-inclined channel or series of channels, so as to settle out the coarser material, and then to run into a large tank or pit, where the finer particles are deposited by quiescent settling.

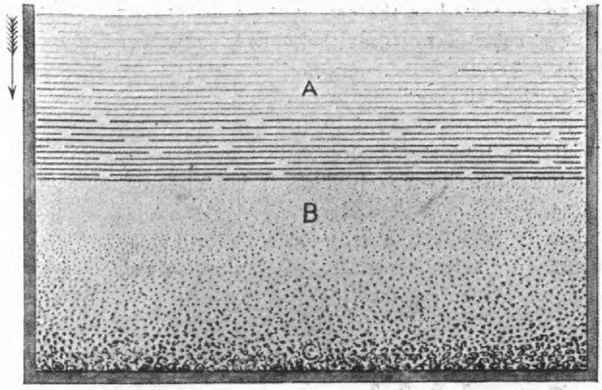

FIG. 1.

The slide now on the screen is a photograph of a "mica-drag," as it is called, taken at a China clay works in Cornwall. It is a typical illustration of the methods at present employed. Water containing in suspension the China clay is allowed to flow slowly along the parallel channels, wherein the fine sand and mica are deposited, and at the end of these channels it runs into the settling pits, seen in the distance, where the final settlement takes place.

It is not possible to get a perfect gradation by this method, as the channels are continually altering in level, because of the gradual silting up of the sand that takes place, the result being that the product from the settling-pit is usually found to contain some coarse material, and that the refuse in the channels has some fine clay with it.

The new process which I now have pleasure in bringing before you is a mechanical method of separating the solid matter from the water and, in the same operation, grading it. The process consists in passing the liquid containing the solid matter in suspension through a rapidly rotating drum, whereby the solids are caused by centrifugal force to be deposited on a removable lining on the inner surface of the drum, whilst the water or other liquid passes away clear of suspended matter. The essentially new and valuable feature of the apparatus is that a current of water is produced through the drum from end to end whilst the machine is rotating, with the result that the solids are deposited in the order of their mass, the largest and heaviest near the inlet end, and the finest and lightest near the outlet end, with every degree of fineness in between.

The apparatus is seen in sectional elevation in Fig. 3, and in cross-section in Fig. 4. The drum, *A*, fitted with a base, *B*, is mounted on a shaft or spindle, *C*, the whole being suspended from a ball-bearing of special design at *D*, supported between girders at *E*. Rotation is imparted by the pulley, *F*, to which a band-brake is fitted at *G*.

The upper end of the drum is closed by a cap, *H*, which makes a watertight joint with the drum at *I*, when clamped by the locking-ring, *J*. This forms a species of bayonet joint.

The cap, *H*, has a hole in the middle, and is held central on the spindle by means of the casting, *K*, which is a sliding fit on the spindle, and is connected with the cap by the upper ends of the six rods, *L*. At the bottom of the drum at *M* is fitted a weir-plate or diaphragm.

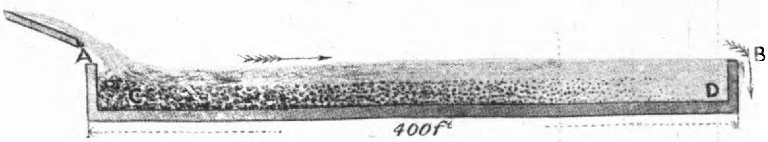

FIG. 2.

Depending from the cap into the drum is a kind of cage, seen best in the section, consisting of six vertical square rods, *LL*, to which are attached radial vanes or blades, *NN*. These blades extend the whole length of the drum,

being connected to the cap at the top end, and to a circular plate, *O*, at their lower end. The slide will make the "container," as it is called, quite clear to you.

The container slides easily in the drum, which it divides into six longitudinal compartments. Each compartment is provided with a curved plate, *P*. It will be understood that the container is, in effect, a removable lining to the drum, on which the recovered solids are received,

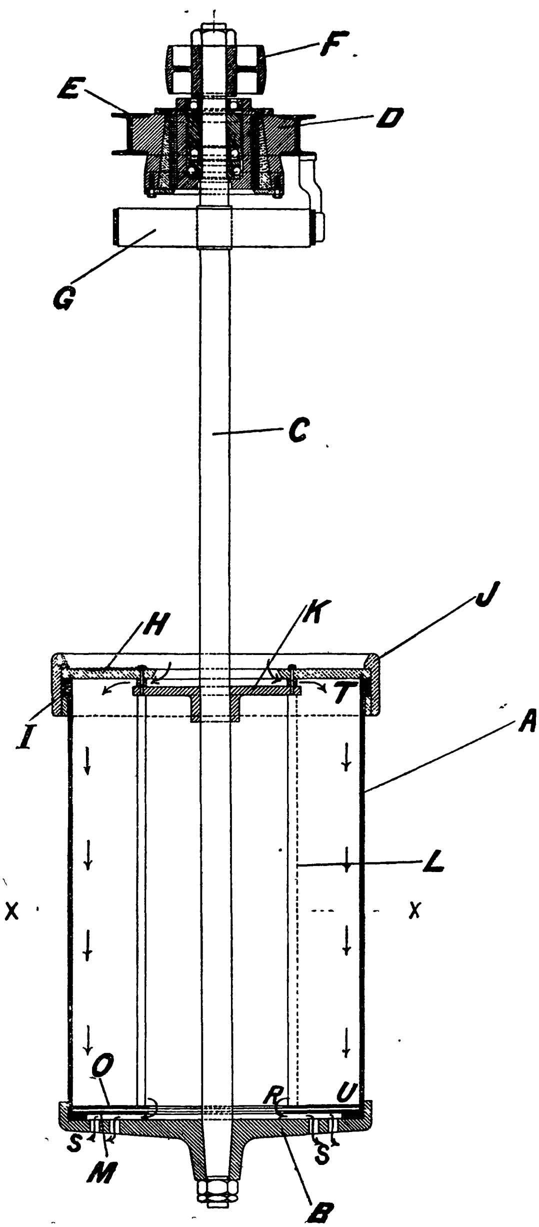

FIG. 3.

as shown in the horizontal section at *Q*. The operation of the machine is as follows:—

The requisite speed (usually between 100 and 200 ft. per second peripheral velocity) being

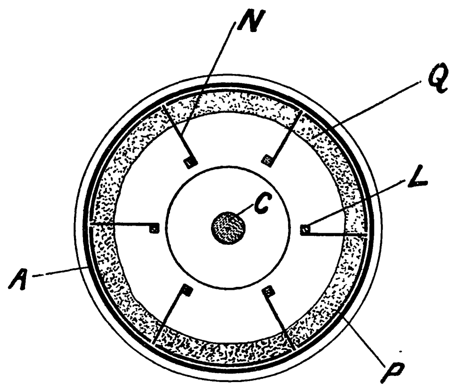

FIG. 4.

attained, the water containing in suspension the solid matter to be separated and graded is fed in a steady stream through the hole in the middle of the cap on to the casting, *K*, which also serves the purpose of a distributing-plate. The centrifugal force generated by the rapid rotation causes the water to fly to the wall of the drum and distribute itself thereon, so that an inner wall of water is soon formed which, when a given thickness is attained, overflows as indicated by the arrow at *R*, and passes out of the drum through the holes in the bottom, under the weir-plate, *M*, at *S*.

It will be understood that a slow, steady current of water is thus set up in the drum, in the direction of the arrows, and in passing down the drum, the solids in suspension are gradually deposited on the plates which line the drum. The coarse or heavy particles are very quickly separated, and these are found near the inlet at *T*. The finer particles are carried further along before they become separated, until the finest are deposited at *U*, near the outlet.

Consequently, the slab of recovered material ranges from the coarsest at one end to the finest at the other, with every possible degree of quality in between. The effluent water is quite clear.

When a sufficient charge of material has been recovered, the machine is stopped, the cap is unlocked, and the container drawn up by lifting gear (not shown) until the bottom plate, *O*, is within a few inches of the top end of the drum. The slides show views of the machine with the container in the raised position ready for

Hosted by Google

discharging. The curved plates can readily be removed, with the slabs of recovered material adhering to them, fresh plates are inserted, the container is lowered into the drum and locked,

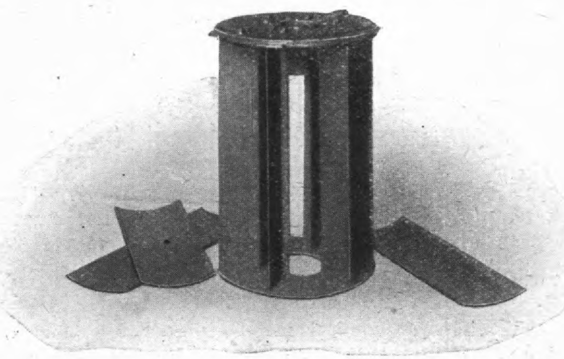

FIG. 5.—CONTAINER, SHOWING CURVED PLATES ON WHICH THE SEPARATED MATERIAL IS RECEIVED.

and the operation repeated. The slide shows a curved plate with the slab of material on it just as it is removed from the drum.

Four to five "journeys" per hour are made, and each operation in the usual-sized drum (3 ft. diameter by 4 ft. 6 ins. long) recovers about a quarter of a ton of graded material.

I have here a small machine which I propose to show you in operation. I must explain to you that it is necessary, in the commercial operation of these machines, that they should be provided with a reasonably firm foundation, or be built into the building in which they are worked; and as we have no arrangements of that kind here, this machine will have to run at a lower speed than would be used in the ordinary way. Luckily the grading effect can be exhibited perfectly at these low speeds, so from that—the most important—point of view, the demonstration will be perfectly illustrative of the results in commercial working. The only effect of the increased speed at which the machine works in actual practice is to increase the yield and to produce a dryer slab.

In order that the demonstration may be more graphic, I propose to mix together these two different coloured materials by stirring them together with water, and then to put the mixture through the separator, when we will find that they are separated from one another again. At the close of the meeting I hope you will be good enough to come and inspect these slabs more closely, when you will be able to see the grading effect produced by the apparatus much more clearly than at a distance

The industrial applications of the process are very numerous. A large number of commodities, such as whiting, fuller's earth, China clay and other clays, ochres, umbers, and other earthy pigments, Tripoli powder, pumice powder, emery and other polishing substances, and so on, are at present treated by first grinding or puddling them with water, and afterwards settling them out of the water in the various grades, in the manner I have already indicated. All these commodities can be treated by my process with results which are entirely satisfactory.

It would take too long, and would involve much repetition, if I were to deal separately and in detail with the application of the process to each of the commodities I have named, so I propose to select one of them, which is fairly representative of the remainder for detailed description. You will understand that, in reference to all the industries I mentioned, the process is equally beneficial.

We will therefore consider the application of the process to the production of China clay, or kaolin. This commodity is produced in Cornwall, and, to a smaller extent, on the edge of Dartmoor, in Devon. The present production

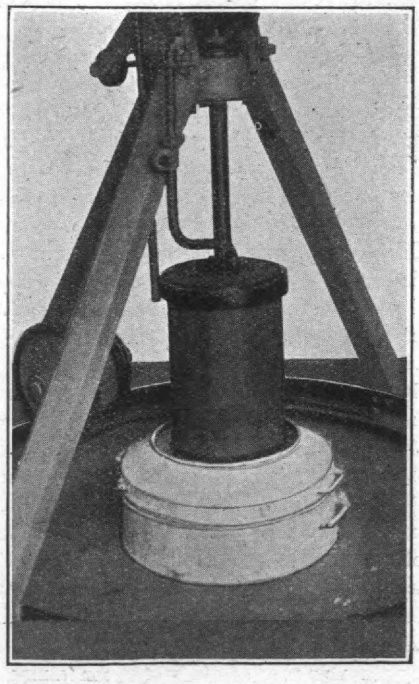

FIG. 6.—MACHINE READY FOR RUNNING.

Hosted by Google

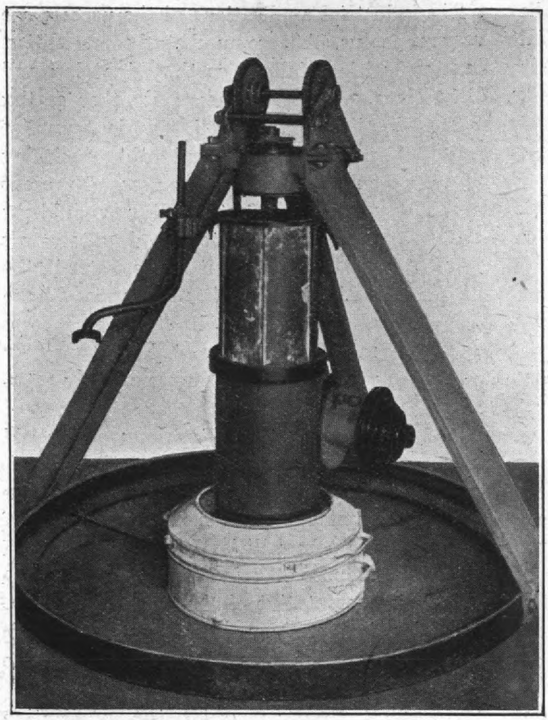

FIG. 7.—MACHINE WITH CONTAINER IN RAISED POSITION.

is about 800,000 tons per annum, and is rapidly increasing. Most people, excepting, of course, those who are directly connected with the industry, are under the impression that the chief use of China clay is in the manufacture of pottery. This is not the fact. By far the largest demand for China clay comes from the manufacturers of paper and textile goods, who use it in the sizing and dressing of their products.

As found in the earth, the raw clay is mixed with boulders, small cubes of quartz, fine sand, and mica. It is washed out of its bed by a species of hydraulic mining, in large open workings, often several acres in extent. The boulders and coarse quartz gravel are left behind in the pit, to be dug out and dumped separately, and the water, carrying in suspension the clay, and with it the fine sand and mica, is pumped up to the top of the pit. After passing along the channels, or "mica-drags," it is settled out in settling-pits, whence, after standing for two to three weeks, so as to get as firm a sediment as possible, the water is run off, and the clay is ladled out in the form of thick sludge, and dried in kilns, called locally "drys."

By the new process the water containing the clay in suspension will be fed into the machines, where the clay will be separated from the water, to put it graphically, in as many minutes as it now takes days. The clay is removed from the drums in a more or less solid state, which, compared with the semi-liquid sludge of the present method, admits of considerable economy in the cost of drying. By the present method, for every ton of clay dried, not less than one ton of water has to be evaporated. The economy in drying cost is not only due to there being less water to evaporate, but is further increased by reason of the new method admitting of the employment of modern air-tunnel dryers, in which warm air circulates round the cakes. This is probably the most economical method of drying. It is considered so in the brick and tile industry, where it is in general use. Although warm air drying is so superior to kiln drying, it is not practicable with the semi-liquid sludge which has to be dealt with now in Cornwall. It is not an unimportant point that, in drying by warm air, all risk of burning the clay is avoided. It is therefore claimed that, directly and indirectly, the use of the new process will effect economies to the extent of at least 4*s*. per ton in the cost

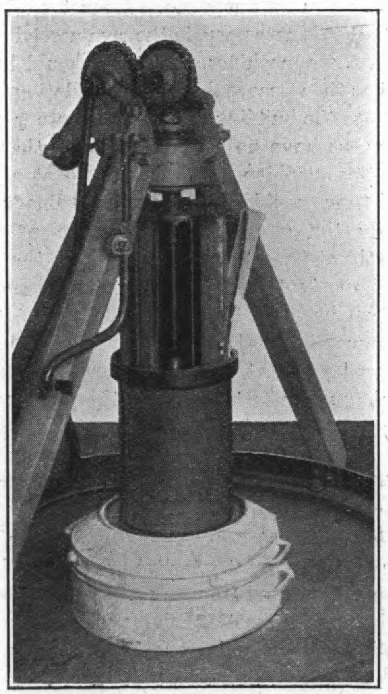

FIG. 8.—MACHINE SHOWING HOW SLABS ARE REMOVED.

Hosted by Google

of producing the clay, which cost now averages about 10*s.* per ton, or, in other words, a saving of 40 per cent.

But this is not the principal advantage of the process. The standardisation of quality, which the grading effect of the process provides, is even more valuable. It is easy to arrange that the machines shall all rotate at the same speed, and be fed through the same sized pipe, and therefore the slabs of recovered material must always be alike. As, by means of a gauge, the different qualities can be exactly separated, it follows that absolute standardisation of quality can be relied on. The highly-refined, superfine clay from the fine end of the drum is a quality

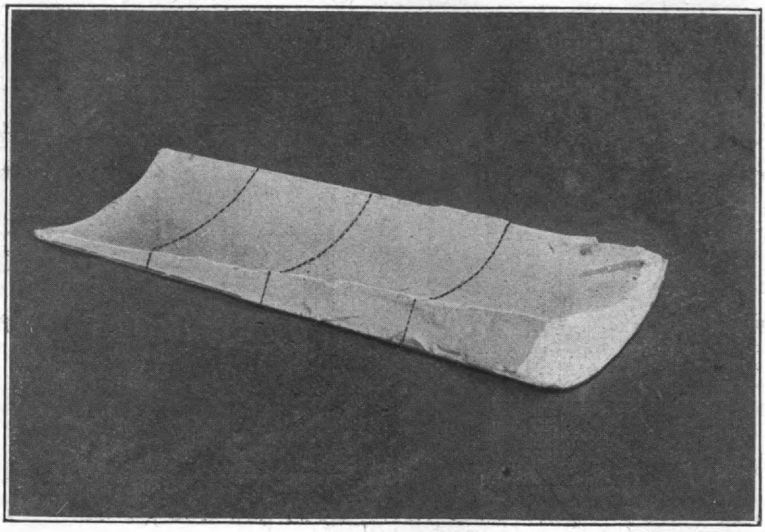

FIG. 9.—SLAB OF RECOVERED MATERIAL, SHOWING HOW THE GRADES ARE CUT.

absolutely unknown on the market at present, which will command very high prices. An average sample of China clay, as now produced, was re-treated by this process, and the graded clay thus obtained was submitted to commercial valuation. The report received showed an average increase in value of 6*s.* per ton. If we now add together the 4*s.* saved in cost of production and the 6*s.* increase of value, owing to superiority of quality, we get an advantage of 10*s.* per ton to the producer over and above his present profits. This should lead to some interesting developments in the China clay industry, as the finished clay now goes aboard ship at an average price of something less than £1 per ton.

This necessarily brief sketch of the application of the process to a representative industry will serve to give an idea of its value in relation to all other allied commodities which are now produced by levigation or elutriation in water. The advantages obtained may be summed up under two heads:—

1. Saving in cost of production by reason of greater efficiency of plant, lower labour cost, and lower capital cost.

2. Increased value of product, because of exact and reliable standardisation of quality.

The machine you have seen is also applicable to the separation of solid matter from liquid where grading is of no importance, but the object is mainly to get the suspended matter out of the water as quickly and cheaply as possible. The machine is very efficient, considered from this point of view only, much more so than the method frequently adopted of filtering through cloths, etc. In this connection, I have recovered waste fibre from the effluent water of paper mills, clarified the effluent from collieries, etc. I am now investigating the application of the machines to the treatment of sewage or sewage sludge.

Mentioning collieries reminds me of a very interesting experiment I made recently. A sample of coal was sent to me, containing about 16 per cent. of silicious ash. The object sought after was the removal of the silica from the coal. I had the coal crushed to fine powder, and was able to get a very satisfactory result. This will probably be of great importance, as there are, I understand, in some of the colliery

Hosted by Google

districts, millions of tons of dumps, consisting of waste coal, which would be very suitable for coking purposes or briquetting, if only the silica could be got out of it. I have no doubt, from what I have done, that we shall be able to convert this waste material into a valuable commodity.

I would now like to deal with a mechanical problem which had to be solved during the early work on this process. When a body such as the drum of this machine, which is longer than it is wide, is set rotating at a high speed, a precessional movement is set up. In other words, the axis of the machine wants to rotate around the centre line, just as the boy's peg-top, when it begins to spin, "wobbles" for a while, and then "goes to sleep," as we used to say when we were schoolboys. Now, if we hold the machine rigidly in bearings at each end of the spindle, this precession at high speeds becomes converted into a constant vibration, to overcome which a very heavy framework and substantial foundations are necessary.

It is usual, therefore, in all centrifugal machines, to suspend them from one bearing at the top, and hold the housing of this bearing in rubber washers. This is done so that the machine may, within limits, "wobble" as much as it wants to, and finally "go to sleep." The usual kind of bearing was, however, insufficient for this type of machine, with a drum whose longitudinal axis is greater than the diameter, and it was only after much trouble and experiment that the bearing shown in Fig. 10 was evolved.

In this figure, *A* is the spindle of the machine, which is fitted with two radial ball-bearings, *B*, separated by a distance piece, *C*. The weight of the machine is taken by the thrust ball-bearing, *D*, through the thrust collar, *E*. These ball-bearings are enclosed in the housing, *F*, which is furnished with an outward flange at the top, which prevents the housing from slipping through the rubber washer, *G*. This is a cylindrical tube of rubber completely embracing the ball-bearing housing, and is in its turn enclosed in a collapsible steel cone, *H*. This steel cone is made collapsible by means of a number of saw cuts in alternate directions. It fits a corresponding cone in the casting, *I*, and by means of the nut, J, the collapsible cone may be screwed up and so made to compress the rubber cylinder to any desired extent. This adjusts the control which the rubber exerts on the precessional oscillations of the drum. The plate, *K*, at the bottom prevents the rubber cylinder from being drawn through the cone.

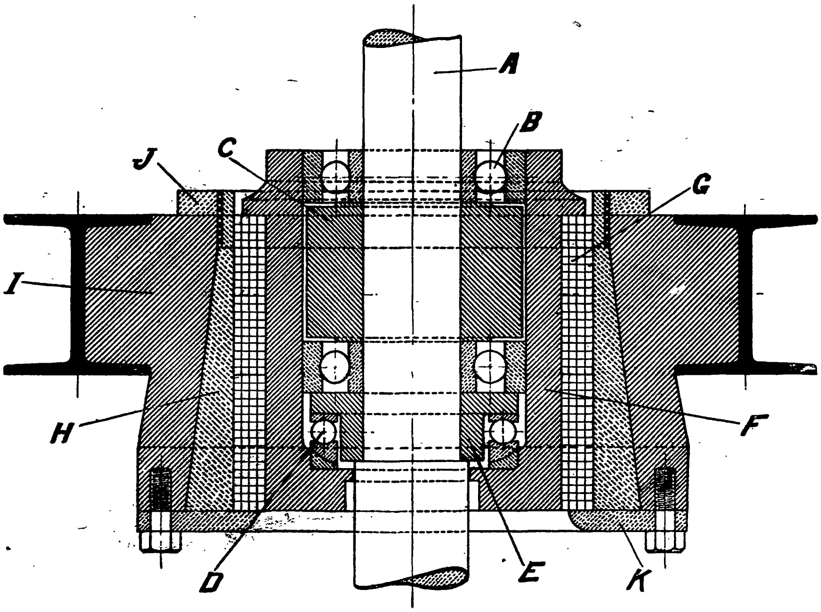

FIG. 10.

The effect of this specially-devised bearing is that the drum, after a few oscillations at starting, runs perfectly quietly and smoothly, and, as it runs on ball-bearings, the power required to maintain it at speed is very small. As to lubrication, the bearing only needs to be filled with

lubricating grease every two or three months to keep it in perfect order.

I am glad to say that the apparatus is very unlikely to get out of order. There is only the one bearing, which, as you have seen, does not require frequent attention, and there are no complicated or difficult parts anywhere else. The operation of the drum, too, is simple. All the attendant has to do is to arrange that the water containing the suspended matter is fed in at such a rate that the effluent is just clear. That indicates that the machine is working at its greatest efficiency at the particular speed at which it is running. If, by accident or carelessness, the attendant feeds too slowly, the result will be that the slab of recovered material will not be properly spread over the whole length of the drum, but will be too thick at the coarse end, with very little, or nothing, at the fine end. If, on the other hand, he feeds too quickly, he will lose some of the fine stuff with the effluent water, because the material will not be long enough in the drum to separate all of it. These faults will be immediately recognisable when the drum is discharged, and the remedy will be at once apparent. If, again, he forgets to lock the cap, he will get a shower-bath to remind him of his omission, but in no case will the machine be likely to be put out of order by any carelessness or stupidity on the part of the attendant. Naturally, the rapidly-rotating drum must be fitted with guards, in the same way as all high-speed machines are protected. In most cases it will be found the most convenient method to run the machine in a pit, with the top of the cap level with the floor, or, if not, a floor for the workmen will be erected at that level, which is the most convenient for access to the container in the raised position when the slabs are withdrawn.

I have not the time, nor is this the occasion, to go into the more or less abstruse mathematics of the process, but I want to mention one problem to which I would like a solution; and I bring it before you in the hope that someone present can evolve for me the required formula. You will know that, in dealing with compressed air, we speak of the compression being equal to so many "atmospheres," that is to say, so many times the normal pressure of the air. Now, I want a formula for calculating the separating efficiency of these machines in "gravities." I have, of course, been able to arrive at a working solution by the simple method of taking the time of quiescent settlement, and comparing it with timed results with the machine, but I feel sure that a simple formula should be available, although I have not hit on it.

I hope I have now succeeded in giving you a good general idea of the separating and grading process, and its varied application to industrial purposes, and I now propose to deal with a new departure which I have made in the direction of applying the process to ore separation. I may mention that, from the earliest time, I have had it in mind to investigate the possibility of treating ores by centrifugal methods, and I had no chance of forgetting it, because nearly everybody who saw the process in operation said, "Why don't you treat ores by it?" I took an early opportunity of putting some water-suspended ore through, but I found it was only a qualified success, because the machine separates not only as to the specific gravity of the particles, but also as to the size of them. Consequently, when crushed ore was suspended in water and passed through the drum, the metallic particles came out at the top end of the drum, but so also did the coarser particles of the gangue, and similarly at the fine end there were usually some extremely finely-divided particles of metallic mineral, especially when tin ores were being treated.

I therefore waited until the process I have already shown you was perfected, and the machines being made commercially. Then I felt at liberty to devote myself particularly to the study of ore treatment, where the object sought is separation entirely as to the specific gravity of the particles without any reference to the size of them. I took an opportunity of observing the usual concentrating tables, vanning machines, buddles, etc., at work on various mines in Cornwall last summer, and I finally summarised the principles employed in existing mechanical concentrating plant into one governing proposition, viz., that the crushed ore, being suspended in water, is submitted to two forces acting at a right-angle to each other: (1) the force of gravity, causing the metallic particles, by reason of their greater inertia, to tend to remain behind; and (2) the flow of the water, which carries away the lighter or gangue particles.

In the end I evolved a separator of a new type, which carries out these two essentials. This is illustrated in Fig. 11 in sectional elevation, and in cross-section in Fig. 12. In this machine we have the drum, *A*, mounted on the base, *B*, and closed at the top by the cap, *C*. Ball-bearings, *DD*, at the top and the bottom of the

Hosted by Google

drum are placed so that the drum may rotate on, but independently of, the shaft or spindle, *E*. I should mention here that, as this ore machine runs at a lower speed than the grading-machine, there is no objection to putting bearings at both ends of the drum. The weir-plate at the bottom, inside the drum at *F*,

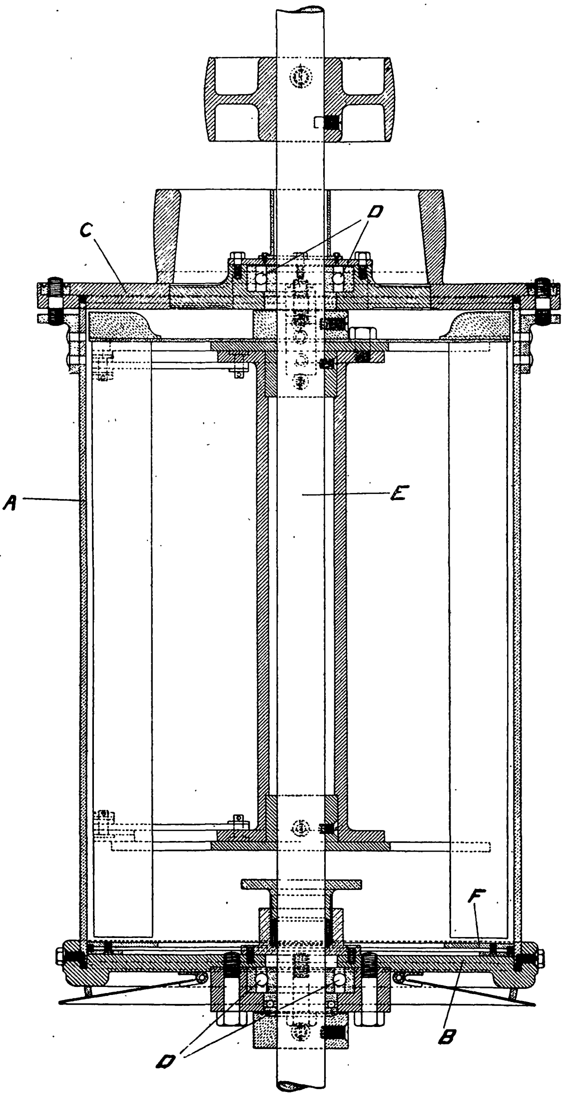

FIG. 11.

serves the same purpose as in the machine you have seen—namely, to provide an inner wall of water of the desired thickness within the drum. The shaft, *E*, is fitted with bearings at each end, and attached to the shaft, within the drum, but clear of it, are a number of radial vanes or blades, extending the whole length of the drum, and so arranged that the distance for which they dip into the wall of water may be varied, so that the grip of these blades on the water may be adjusted.

The principle of the apparatus is that the drum is caused to rotate at a given speed, and the wall of water is caused by the vanes to rotate within the drum at a greater speed, but in the same direction. These speeds, and their ratio to one another, may be adjusted within very wide limits. The result is that the particles of greater specific gravity—for instance, tin oxide, with a specific gravity of 6·7—are, by reason of their greater inertia, caused to deposit on the drum and remain there, whilst the particles of lesser specific gravity—let us say quartz, with a specific gravity of 2·65—are carried along with the water and discharged with the effluent. You will have understood, from what you have already seen, that centrifugal force acts, in these centrifugal machines, in precisely the same way as gravity does on a concentrating table. The only difference, so far as the effect is concerned, is in the intensity which, in this machine, is about a hundred times as great as on the concentrating table. It is easy to adjust the speed at which the water travels relatively to the drum, so as to effect practically a perfect result.

The method of operating the separator is as follows:—The drum and the vanes are set rotating at the required speeds, and clean water is fed into the drum until an effluent is observed at the outlet. This indicates that the wall of water in the drum has been obtained. The inflow is now changed to water-suspended ore, whereupon the separation of the metallic particles is effected, as I have just described, during the passage of the material through the drum, and the effluent will consist of water-suspended gangue only. The inflow of ore is continued until a sufficient deposit of concentrates is obtained, and it becomes necessary to discharge the metallic material. The discharge is effected in the following manner:—The inflow is changed over from ore-water to clean water, and in a short time all the gangue still in the drum will have been carried away and the effluent will be clear. There will now be in the drum only a wall of clean water, with a thin layer of concentrates adhering to the inner surface of the drum. The effluent is now changed over to the waste, and put into communication with the reservoir for concentrates. The drum is then retarded or stopped whilst the vanes still rotate. The stirring action of the vanes is thereby increased to such an extent that the concentrates are washed off

Hosted by Google

the drum, and the continued inflow of clean water carries them away to the reservoir. In a few seconds the drum is quite clean. The effluent is now reconnected to the waste, the speed of the drum is restored to its proper ratio, the inflow of ore-water recommenced, and the cycle of operations repeated. Gearing will be provided whereby these operations are periodically performed mechanically, and the apparatus rendered wholly automatic.

It will be understood that the apparatus must be carefully adjusted by a skilled metallurgist to the material to be treated when it is first set up. He will have a rough guide furnished him, but he will have to make experimental runs, and test the results by analysis or assay. There are five different factors in adjusting the apparatus, viz. :—

1. The speed of the drum.
2. The speed of the water.
3. The grip of the vanes on the water, varied by moving them towards or away from the drum.
4. The thickness of the wall of water.
5. The rate of flow through the drum, which varies the time during which the material is being acted upon.

This preliminary adjustment, although it sounds rather formidable, is really not very difficult, but it is worth while to spend some time on it, because once the apparatus is adjusted to the particular material to be treated, no further skilled attention is required. In fact, the only labour of any kind that will be required will be for the purpose of keeping the plant supplied with material on which to work, and every month or so filling the ball-bearings with lubricant.

The ore must be crushed or ground sufficiently fine to ensure that the particles of metallic material are separated from the gangue particles. It will be obvious that if we have a particle of material which consists of a mixture of the metal and the gangue, then the specific gravity of that particle as a whole will be somewhere between the specific gravity of the gangue and the metal respectively. It is this factor that accounts for the relatively poor extraction of tin by Cornish mining methods. The tin oxide, or some of it, exists in such a finely divided state that extremely fine crushing is necessary before the metal particles are separate from the gangue particles, and, until that condition is arrived at, the difference in specific gravity between the particles, which is all we have to rely on for effecting a concentration, does not exist, or, at best, exists only partially.

There is no difficulty in grinding the rock finely enough at a reasonably low figure, but the trouble hitherto has been that the present mechanical concentrating methods are not suitable for the concentration of finely crushed ore; in fact, it is usual at present to regard crushers as efficient or the reverse, according to the amount of "slimes" they produce. As slimes are at present a bugbear to the ore-dresser, he wants to avoid making them as much as he can.

I am glad to be able to tell you that I have treated slimes in my ore separator, and I find that they can be concentrated perfectly; in fact, since, as I have shown you, fine crushing is essential to a rich concentrate and a high percentage of extraction, I prefer that the ore be crushed as fine as possible—the finer the better.

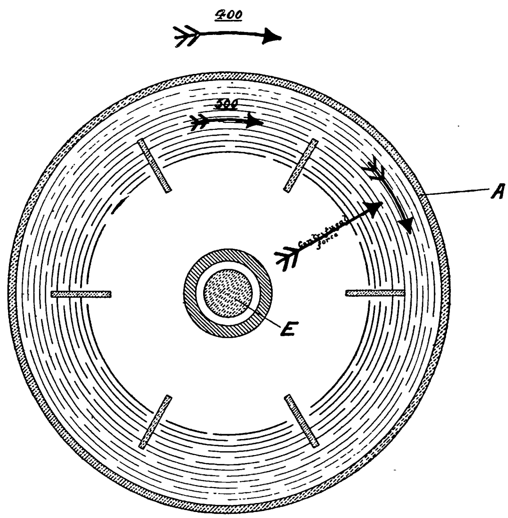

FIG. 12.

I am told that the hardest rock can be reduced to fine powder or slime for under 1*s*. per ton by a new method of dry-grinding that is now available. It is a matter of common knowledge in Cornwall that tens of thousands of pounds' worth of tin is running away down the rivers into the sea every year because it is too fine to be recovered by present methods. I expect to be able to put an end to that state of things.

Although the ore separator is a quite recent development, and I have therefore not yet had time to examine and work out all the various ramifications of the process, I have been able to make a series of practical tests. From what I have already done I feel justified in claiming that this process will do everything that the present mechanical concentrators will do, but

Hosted by Google

in a much more economical and efficient manner. I expect to get a 95 or 97 per cent. recovery of the metallic content of an ore. In addition, the process will treat to great advantage ores which have up till now defied mechanical treatment. It was found impossible to arrange in time to have an ore separator at work here to-night, but I have here some samples of treated and untreated ore, and I hope that you will come and examine them at the close of the meeting.

It may seem to you that the claims I have made for the process are too optimistic, but I can only say that they are based on practical results. The simple explanation is, that whereas the usual concentrating tables and vanning machines use only the force of gravity, the Gee concentrator employs centrifugal force, which, although otherwise precisely the same in effect, may be varied at will, as regards its intensity, by varying the speed of the drum. The precision with which the process may be adjusted is sufficient explanation of its seemingly marvellous efficiency as regards percentage of recovery and richness of concentration, and the magnification of gravity (for this is what it really amounts to) which is brought about by the use of centrifugal force is the measure of the increased output, as compared with ordinary methods of mechanical treatment. The separator will run at a power cost of considerably less than one penny per machine per hour, and each machine will treat at least two tons of ore per hour.

I am now pushing on as rapidly as possible with a large separator, embodying all the minor developments which suggested themselves during the work with the first apparatus, and I expect to be able in the near future to collect authoritative data as to the performances of the process in commercial work on various kinds of ore.

In conclusion, I express the hope that at a later date I shall again have the privilege of addressing you here, and giving you more definite and established information about the ore concentration process than at this early period it is possible for me to give you.

DISCUSSION.

DR. E. FEILMANN, in opening the discussion, thought the method of calculating the force exerted on each particle in terms of the ordinary action of gravitation as a unit was fairly simple. The centrifugal force on a particle revolving with a peripheral velocity of v at a distance of r from the axis of revolution would be $\frac{v^2}{r}$, according to a well-known formula. Calculating on that basis, for a drum of three feet internal diameter, with a velocity of revolution at the periphery of 200 feet per second, it would be found that the action at the surface was 850 times that which was due to gravitation, which apparently showed a very considerable advantage in that direction. There was another feature of the process, looked at from a mechanical point of view, which might be of importance. If instead of taking the peripheral velocity and the radius of the drum, the formula was expressed in terms of angular velocity, varying the radius, the formula was obtained of $4n^2\pi^2r$, for the centrifugal force, where n was the number of revolutions per second. The important point of that was that the action exerted on each particle varied directly as the distance from the centre of revolution, and there was, therefore, a constantly increasing force acting on each particle as it traversed the layer of liquid from the inside layer to the outside of the drum. This was a different effect from that obtained with an ordinary concentration table, where the force of gravitation acting on the particle was the same throughout. He had not gone into the question of exactly how that affected the grading, but although he would not like to dogmatise about it, it looked as if it might help the process at that point.

MR. A. CAVIN HODGE, after congratulating the author on the very beautiful photographs he had shown of the clay pits at St. Austell, of which place he was a native, said that if Mr. Gee's invention was as good as he had given his audience to understand it was, he was sure the whole of the clay district of Cornwall would be only too pleased to adopt the process. The author had not stated whether the machine was to operate in the pit, or whether the water was to be pumped, as it was at present, to the surface, and subsequently to go through the machines. If the latter was the case, he thought the machine would have very little duty to do. That was a question which from a commercial point of view particularly interested St. Austell men. Another practical point was that a certain amount of iron existed in some of the clay works, and it was well known that a small percentage of iron was detrimental to the concentration of the clay. Would Mr. Gee's machine assist in freeing the iron from the clay, or would it still remain in the clay?

MR. RENOLD MARX said the author had stated that his apparatus was peculiarly fitted for the recovery of fibres from the backwater of paper-mills, and it would be interesting to hear whether any figures were available as to the performance of the apparatus on that class of work. The principal method in use at present in paper-mills was that of decantation. The apparatus embodying that principle was an extremely simple one, and the results obtained by the author's apparatus would have to be very good indeed to be of practical commercial value to paper-makers.

MR. W. H. PATCHELL asked the author whether the 800,000 tons of clay, which he said in his paper

Hosted by Google

were produced per annum, related only to clay, or included China-stone, and mica-clay. If, as the author stated, those 800,000 tons were worth £1 a ton, and the machine increased the value by 6*s.* a ton, it represented a gain of £240,000. From a commercial point of view it would be interesting to know whether, if clay went up in price from 20*s.* to 26*s.* a ton, there would be a market for it. Would people who now paid 20*s.* fall over each other to pay 26*s.*, or would there be a smaller demand for the 26*s.* clay? The author had not stated what percentage of water was contained in the clay as it left the machine. From the sample the author had shown it looked pretty much the same sort of clay that was generally put on a pan, and that contained at least 50 per cent. of water. If the machine was run longer with a solid back similar to that now used, he was not sure that the clay would be obtained very much drier. With a perforated back a certain amount of clay would be lost, but the clay that stuck to the back would act as a filter, and a very much drier residue would be obtained than when working with a solid back. The author had further stated that ore could be ground for a shilling a ton. It would be interesting to have further particulars of the cost of the grinding, and the cost of the power used. Did the penny an hour, at which the author said the machine could be run, represent a pennyworth of coal or of electricity; and if the latter, what was the price per unit? With regard to the question of settling, the particular water used made all the difference in the rate at which the material would settle in the water. When Archbutt and Dealy started water-purifying, they found that if yesterday's dirt was stirred up from the bottom of the tank, the next day's lime crystals settled very much more rapidly than if the tank was absolutely clean and the day's dirt was settled by itself. People working that process always left a certain amount of dirt in the tank, the usual practice being to blow it up with an air jet, so that a thorough mixture was obtained of so much of yesterday's dirt with its larger crystals, and the next day's dirt with its finer crystals. If a start was made with clear water and no yesterday's dirt, and a little alum was put into the dirt, it brought the clay down very quickly. Aitchison, who had been working very much on those lines, and who had dealt with the question of flocculation, had found that if straw was put into the water it very much increased the rate of precipitation. In reply to the previous speaker, who asked if the machine would bring out the iron, he thought it would not, because iron was not brought out by ordinary gravity. The author's machine did not act on any other principle than ordinary gravity, except that it hustled it up a bit.

Mr. W. N. Gardner inquired whether the author had tried any other liquid but water—for instance, oil—in the separation of ores. He thought that, if the ores were first passed over oil, some very interesting results would be obtained.

Mr. Walter F. Reid said that, judging from what he knew of the China clay industry, and from the author's statements in regard to it, it would prove rather costly to work with a machine similar to that shown. It would be interesting to know what the cost of labour was for clearing out the clay per ton. It also seemed to him that if the value of the finer portion of the China clay was increased, the quality of the coarser portion would be deteriorated almost to the same extent. Were the audience to understand that the whole of the material was increased in value or only a portion of it? In his opinion the process could be adapted more or less to materials of the same kind rather than to materials of a different kind. It was evidently a splendid grading machine. If emery or any material that would stand the action of water was ground to different degrees of fineness, it seemed to him the principle would work very well indeed. He was inclined to doubt the figure given for the cost of power, and would like to know how it had been arrived at. It would also be interesting to know whether the machine would separate, for instance, particles of clay and chalk. In the cement industry there was an enormous field for separating the "slurry" quickly, and if it could be utilised cheaply in the industry that was an application of the author's invention at least as big as its application to China clay.

Mr. W. S. Lockhart, in dealing with the question of different specific gravities, thought it would be as well to add in the third paragraph of the paper that the separation being effected in the long channel was effected on material of the same specific gravity. He thought that that was what was intended, and it would be as well to say that the question of the specific gravity did not come in there. It was only intended if materials like China clay or mica were used. In the final paragraphs of the paper another correction was required, where he thought the author meant to convey that the value of the process was dependent upon the smallness of the amount of slimes produced, and not upon the amount of slimes produced. It would be interesting to know what percentage of speed would be allowable to make any very serious difference in the results obtained from the machine. Centrifugal machines had previously been used for ore-dressing, and the great trouble experienced had been to get even turning from the beginning to the end of the day. Even very small differences in the speed of the engine would make a considerable difference. Several machines based on centrifugal force had failed for that reason, and he would like to know to what extent this would affect the author's machine. It was interesting to hear that, by application of centrifugal force, very finely divided ground ore could be treated, because those

Hosted by Google

who were accustomed to ore-dressing knew that after a certain point fine materials did not behave well in ordinary water, the water not being liquid enough. If the ore could be dressed with oil or turpentine, much better results would sometimes be obtained, but if centrifugal force would do the same work with ordinary water it would be a very great advantage to the mining industry.

MR. A. L. JOHNSON inquired whether the author used any special type of motor to drive the machine, and the kind of current used.

THE CHAIRMAN, in concluding the discussion, said that one great advantage of the author's machine was its simplicity, and from the test which had been carried out in the presence of the audience the difficulty of the precessional movement, so far as he was able to judge, had been overcome. The reason that the residue was rather moist, a point to which Mr. Patchell had referred, was probably due to the fact that the machine was not driven at the proper speed. Ever since the time of Adam people had been endeavouring to evolve a process for the separation and grading of solids suspended in liquids, and it was therefore extremely difficult to produce anything new on the subject. The market was full of machines of different sorts, and if Mr. Gee had discovered a way of successfully dealing with the problem he was heartily to be congratulated, but it was only possible to judge of the success by the results obtained. Still he thought that what the author had shown had, to a certain extent, solved the problem.

MR. W. J. GEE, in reply, said he was exceedingly obliged to Dr. Feilmann for the formula he had given, the result of which, 850 gravities at that speed, was, he thought, theoretically correct. Observed by timed results, the effect was, at the speed he (the author) gave, as nearly as he could say about 475 times the force of gravity. In order to get a real result it was necessary to take the mean thickness of the wall of water, and from observed results it was very difficult to say whether the time of settling in a vessel had been quite correctly observed. With regard to the question of placing the machine in the pit, obviously his process was a substitute for settling-pits, the claim being that the machine effected practically instantaneously what occupied a long time in settling-pits. With regard to the question of the improvement in the value of the clay, all kinds of samples of clay had been sent to him from Cornwall, and he had always been able to produce at the fine end of the slab some exceptionally fine clay, finer than the finest clay he had ever seen. His method of separation and grading was practically mathematically accurate, a result so accurate being obtained that it was possible to produce a standard quality. He had dealt with the question in the paper from a scientific point of view, and he was not present at the meeting to advertise the process, but he would be very glad to supply further details if communications were sent to him. With regard to the question of the percentage of iron, he had received chemical analyses from one of the leading authorities on clay, taken from various portions of the drum, which showed that there was considerable diminution of the quantity of iron as between the coarse end and the fine end of the drum. Iron was present in the clay in two or three different forms, and it was very difficult to say whether the iron was got out by reason of the fact that it had a greater specific gravity, or on account of the size of the particle, or whether it might be true that some of it was combined with the coarse particles. From the point of view of the analytical result there was a considerable improvement, not only in the fineness of the particle at the fine end of the drum, but also in regard to the iron contents. He had had the opportunity of running the effluent from paper-mills through his machine, with the result that the paper fibres and other suspended matter came out quite readily; in fact, there was very little difficulty in getting almost any suspended matter out of water by passing it through the drum. The question whether it would pay could only be settled by actual experiment. A machine three feet in diameter and four feet six inches high could be seen running in London at a cost of well under one penny per hour. It was safe to say that in almost any part of the country five horse-power could be obtained for a penny an hour, seven horse-power being nearer the average. His machine took between three and four horse-power when running at full speed, but to start with there was an overload of about six times the normal load factor for the purpose of getting up full speed. The question of keeping the speed regular naturally appealed to anyone who was interested in the subject of ore treatment, because speed was most important in dealing with the concentration of ore. Even if the speed did drop, however, the ratio remained the same. He had a machine running at his laboratory driven by an ordinary electro-motor with a controller attached to it, so that by moving the arm of the controller he could obtain any speed desired on the drum for experimental purposes; and it seemed to him it would be easy to put a governor on the machine which would move the arm to and fro and give the exact speed required. If he found in the course of his operations that it would be necessary to provide some means by which the speed must not be allowed to go above or below a certain limit it could easily be obtained. In the ore machine he described, it was intended that the iron should be separated by specific gravity; and it did so very nearly indeed, although he had not actually demonstrated yet the limits as to the size of particle. With regard to the question of the cost of grinding, he had been informed that there was a new grinding apparatus available which would enable the hardest rock to be ground for under ninepence

Hosted by Google

a ton, and in order to be on the safe side he had put down the figure of a shilling. With regard to the cost of labour for handling the China clay, two men would be able to look after four or probably five machines, each producing one ton an hour, so that if sixpence a ton was allowed for labour it was well above the mark. The process, so far as it related to China clay, had to be considered from two points of view—the cost of labour and the quantity of material extracted from the water—but when such a material as sewage, or a material in which there was only a small quantity of solid matter in the water was being dealt with, it was necessary to pay regard to the efficiency of the machine. The quantity of water clarified in a given time would have to be worked out. The figure of 800,000 tons, the estimated production of China clay for 1910, was derived from the Home Office Report of the Inspector of Mines and Quarries.

On the motion of the CHAIRMAN, a hearty vote of thanks was accorded to Mr. Gee for his interesting and instructive paper, and the meeting terminated.

THE RECRUITING OF THE EMPLOYING CLASSES FROM THE RANKS OF THE OPERATIVES IN THE COTTON INDUSTRY.*

This paper records the results of an interesting investigation made by circular and by direct inquiry. Returns received from a number of manufacturers showed that some 80 per cent. of those willing to give information had begun life as operatives or clerks. A direct investigation was then made in a well-known manufacturing town, and it transpired that some 60 per cent. of the heads of private manufacturing businesses owed their position to their own efforts and that they had begun life in the lower economic ranks. The investigation was then extended to spinning; of sixty-five directors of cotton mills, approached by letter, returns were received from forty-five, of whom thirty-three were self-made men. Moreover, a spinning district was visited and a direct investigation was made, which showed that 13 per cent. of the managing directors, 42 per cent. of the mills managers, and 67 per cent. of the assistant managers, came from working-class families or families with incomes about the same as those earned by the operative classes. Having reached these suggestive percentages, the authors of the paper turned their attention to the manner in which the industrial ladder can be climbed in Lancashire by people without capital or influence. It was shown that in manufacturing the small firm still survives. Of the 134 private businesses (manufacturing only) in Bolton, Rochdale, Leigh and Atherton, Burnley and Todmorden and Cornholme, four have less than 50 looms, five have from 50 to 100 looms, eight from 100 to 150 looms, five from 150 to 200 looms, and four from 200 to 250 looms. In spinning, the joint-stock system largely prevails—of 145 spinning firms in a sample district, 135 were public companies, while of sixty-five manufacturing firms, only twenty-three were of that type of organisation —but within businesses of the public joint-stock order progression takes place, so that the man of great capacity may rise to any position. Further, the authors drew attention to the system of renting premises and power (in manufacturing), the selling of machinery on credit and even for part payment in shares, the obtaining of capital in the form of share capital, and the loans to mills which are so popular in Lancashire and are advertised for in the papers like the loans sought by public authorities. Moreover, the recruiting of the employing class takes place to some extent, it would seem, through the commercial classes. The relations of trade unions and of education to the vertical mobility of labour were examined, and it was concluded that the charge that the former gravely retarded vertical mobility had not been substantiated, as regards Lancashire, while emphasis was laid on the latter as a direct contributory cause of advancement from one grade to another. The authors maintained that vertical mobility was to be encouraged in the interests both of the operative classes, whose wages it tended to elevate, in addition to furnishing prospects conducive to hopefulness, and of the community as a whole.

* Abstract of a paper by Professor S. J. Chapman and Mr. F. J. Marquis, recently read before the Royal Statistical Society.

THE HARVESTING OF SUGAR-BEET IN FRANCE.

The harvesting of the sugar-beet in France is usually commenced about the middle of September. It is generally over in a few weeks as it is desirable to expose the soil, as long as possible, to the action of the weather and to prepare the land for the next crop. Another reason is, that if left too long in the ground, the plants are liable to run to seed, and in so doing the roots are deprived of some of their sugar. It is also important to clear away the crops before the early frosts set in, which would be injurious to the roots and detrimental to their yield. Experience is required in order to determine exactly the right moment for taking up the roots. Generally speaking, as soon as the leaves begin to lose their vitality and their dark-green colour, and turn yellow, they should be removed from the ground.

The harvesting of the sugar-beet consists of two different operations, viz., the extraction of the roots from the soil (*arrachage*), and the *décolletage*, or the slicing off, of the tops of the roots, together with the leaves. This part of the root, although containing a certain percentage of saccharine matter, is quite useless for sugar-making, on account of the amount of saline substances found in it. For this reason, in contracts between the grower and the manufacturer, it is usual to stipulate

Hosted by Google

that a generous slice from the top of the beet be taken off before delivery at the works.

The rooting-up of the roots (*arrachage*) is effected in France either by manual labour (*arrachage à bras*), or by mechanical means (*arrachage mécanique*). For the first, which is only practised on small holdings, the labourer simply loosens the soil close to the root with a two-pronged fork, then, taking hold of the plant with both hands, he draws it out of the ground, shaking it at the same time to get rid of any earth or small stones, adhering to it. This is a very slow process, occupying one man from 110 to 130 hours labour per hectare (45 to 55 hours per acre).

The roots are laid on their sides in rows in readiness for the *décolleteurs*, who, armed with knives or other cutting implements, slice off the tops. The roots are then placed in heaps and covered with leaves, in readiness for cartage to the sugar factory. In this way they lose some of the moisture they contain, and decrease in weight. For this reason, the owners of the sugar factories usually stipulate that the beet should not be delivered until forty-eight hours at least after being taken out of the ground.

Harvesting by hand labour has the disadvantage that portions of the roots are liable to break and get left in the ground, and so diminish the value of the crop to the farmer.

The appliances used in France for the harvesting of the sugar-beet by mechanical aid, may be divided into two classes, viz.:—

1. Animal traction;
2. Mechanical traction.

The machines drawn by animals are only suitable for extracting one row, or at most two or three rows of beet, each journey up and down the field, whilst those propelled by mechanical aid are suitable for drawing five to ten, or even twelve rows, at the same time.

The amount of work accomplished by machines drawn by animal power (*arracheuses à traction animale*), may be estimated as follows:—

1 row at time, $\frac{3}{5}$ hectare per day (about $1\frac{3}{5}$ acres)
3 rows „ $1\frac{1}{3}$ „ „ („ $3\frac{1}{3}$ „)

whilst those driven by machinery (*à traction mécanique*), working on eight to ten rows simultaneously, and drawn to and fro with a cable by two powerful traction engines from each side of the field, will clear as much as 10 hectares (nearly 25 acres) per day.

The power required for driving these machines varies considerably. In dry weather, or after a frost, more power is usually necessary. Under ordinary circumstances two horses or a pair of oxen are sufficient for a one-row machine, whilst in very dry weather three or even five pair may be found necessary.

The machines propelled mechanically in use at the present time are of two types:—

1. Those by which the ground is loosened by means of "colters" to some depth below the roots, which are then, by some suitable mechanism, pulled out of the ground (*arracheuses fouilleusés*).

2. Those by which the ground is only slightly moved (*arracheuses non-fouilleuses*), and the roots seized by some arrangement for drawing them out of the soil.

The machines of Fowler, Candelier, Bajac, Amiot, etc., belong to the first type, whilst the second are represented by the machines of Frennet-Wauthier, Pruvot, etc.

HOME INDUSTRIES.

Railway Dividends.—It is not likely that the railway dividends for the second half of 1911 will be generally increased as compared with the corresponding period of 1910, but the past half year was an exceptionally prosperous one, notwithstanding the labour troubles. Gross earnings largely increased, coal was relatively cheaper, and the better methods of operation recently adopted, and the co-operative arrangements come to in the past two or three years, have conduced to the improved results. Then the capital outlay, which used to average about £20,000,000 per annum, has been reduced to from four to six millions per annum, so that there is very small increase in capital charges. But although profits would, taken by themselves, warrant improved distribution, it may be expected that, having regard to the labour outlook, and what it may involve, most of the companies will maintain, but not increase, the distribution they made for the second half of 1910, carrying the additional profits earned to reserve for contingencies. It must not be forgotten that the new rate of wages, which brings up the minimum wage to £1 per week for practically all grades, prevailed for only a few weeks of the past half year, so that the increase in the wages bill—including the increased expenditure incurred during the strike period—for the six months is not likely to be a large one as it must be in the current half year. Then, again, the trouble amongst the miners, however it may end, is pretty certain to put up the price of coal, a very serious matter for railway shareholders. On the other hand, given normal conditions, it may be expected that the activity of trade, and the increased spending power of the community, will result in a large increase in gross earnings in the current year. The figures for the past half year show that the gross earnings of the nineteen principal English railway companies have increased about 2·3 per cent., while for the twelve months the increase has been about £2,700,000, or 3 per cent., about 40 per cent. of the increase being in passenger earnings. It may be noted that the South-Eastern has done exceptionally well with an increase of £86,000 in gross earnings, equal to 3·3 per cent.

Useless Patents.—A case recently decided by Mr. Justice Parker seems to show that it is too easy in this country to obtain patents which cannot be sustained, but whilst in existence operate as a check upon legitimate enterprise. The patent in

Hosted by Google

question was one (number 27,147 of 1910) granted to Mr. J. C. Merryweather for improvements in automobiles carrying pumps, and the alleged invention appears to have consisted in driving the pump by means of a chain. Messrs. Hans Renold, Limited, who are manufacturers of driving chains, applied to have this patent revoked, claiming that the mere substitution of chain driving for some other method of driving, such as by belt or spur gearing, in connection with any particular class of machines, was not proper subject-matter for a patent. It was, they contended, a substitution already made in connection with many different machines, and one which might hereafter be made in connection with many others. To grant patents in such cases would, it was urged, hamper the development of the chain-making industry, and they accordingly petitioned for the revocation of the patent on the ground of want of novelty, prior publication and use, and that the alleged invention was not a proper subject-matter for a patent. When the case came on the patentee consented to the revocation of the patent, but on the question of costs raised an objection that the petitioners had given no notice to him of their intention before commencing proceedings. If they had done so, he contended, he might have surrendered the patent and saved some expense. The Judge, however, allowed the costs of the petition, remarking that it is doing a kind of public wrong to maintain a patent on the rolls when that patent is void.

Trade with Russia.—According to the German-Russian Union report recently issued, which deals with the Russian foreign trade, German trade with Russia is increasing much more rapidly than that of any other country. The total imports into Russia for the first eight months of 1909 were 505 million roubles, during the same period in 1910 they were 630 million roubles, and for this period last year 679 million roubles. The following table shows the value supplied by the principal countries during these periods:—

	Value in million roubles.		
	1909.	1910.	1911.
Germany	230	285	313
Great Britain	84	106	102
United States	36	52	73
France	32	39	35
Austria-Hungary	18	24	23
Italy	7	12	12
Belgium	4·7	4·6	4·3

Perhaps the greater interest now being taken by English financiers in Russian matters may quicken exports from England to Russia before long.

Over-Insurance.—Of late years we have not heard very much about over-insurance, but it is to be feared it is still very common. A case that has just been investigated at Cardiff deserves attention. It was that of a steamship which had been worked at a loss. The total insurance effected on the vessel amounted to £17,800. The value put upon her by the managing owner at the time of her loss was about £8,700. Having regard to her age (twenty-two years), and her build, tonnage and condition, the Court found that her value at the time of her loss was £7,000 for hulk and machinery, £550 for disbursements, and £450 for premium, reducing the value to a total of £8,000. Thus the vessel was over-insured at the time of her loss to the extent of £9,800. The Court further found that the vessel was insufficiently and inefficiently manned for the voyage; that on the night when she went down the watertight doors were not closed, that she might have got much nearer shelter, if not to a place of safety, if the engines had been kept, as they ought to have been, at full speed, and that "neither the master nor the engineer desired to save the vessel."

Cotton Ginnings.—The eighth cotton ginning report of the United States Government shows that up to January 1st the ginnings were 14,332,000 bales as compared with 12,465,298 bales of the 1908–9 record crop. If this margin of 1,867,000 bales is added to the commercial crop (13,829,000 bales) of the year it will give 15,696,000 bales, and as the rate of ginning between December 13th and January 1st this season was still a little ahead of that for 1908–9, this total is quite possible. But the percentage ginned on January 1st, 1909, was rather lower than usual, and the next ginning period may fall behind. But the expectations of a great crop are already fulfilled.

CORRESPONDENCE.

INDIGO STANDARDS.

My attention has been drawn to a paragraph in *The Indian Planters' Gazette* of December 23rd, 1911, quoted from the *Journal of the Royal Society of Arts*, of the first idem, to the effect that a "special committee was about to be formed with the Textile Institute to consider the question of fixing a recognised standard of indigo-blue dyes in cloth, etc."

As I have made a special study of indigo since 1897, when the "synthetic indigotin" was first placed upon the market, I should like, with your permission, to offer a few observations on the subject. The first objection I have to make is that some foreign commercial chemists and their coadjutors declare that "synthetic indigotin" is indigo, which is an impossible absurdity, as it consists of indigotin only, whereas natural or plant indigo contains several ingredients, including indirubin, which do not exist in "synthetic indigotin," and are falsely called "impurities," as I shall explain presently. "Oh, but," someone may say, "indigotin is the sole colouring matters of indigo, and indigotin is therefore indigo pure." I say that it is not. Colour dyers will tell you, as they have told me, that they do not find much difference between "synthetic indigotin" and indigotin exracted from indigo, but they find a vast difference

between "synthetic indigotin" and indigo. All practical dyers also admit that the other ingredients in indigo (made apparent by chemicals), add to the colour-producing power of indigo, and one of the most expert dyers in the country—Mr. Alex. W. Playne, of 9, Stanley Street, Bedford—holds that the whole of a sample of indigo dyes blue, and that the chemicals only spoil it, as it is very sensitive to chemicals. One can understand that from its composition. They also say that changes take place in the vats which enhance the dyeing power of indigo. Prior to 1902, all the "synthetic indigotin" made from coal tar, imported into this country, was under the heading of "other coal tar dyes"; but since that year, it appears on the Returns of the Board of Trade as "synthetic indigo." Now there is not such a thing in existence as "synthetic indigo"; at best it can only be "synthetic indigotin," neither is it "indigo pure," or "indigo rein." All these false descriptions should be absolutely prohibited by all scientific men, and independent journals in this country. Another aspect of these foreign dyes, which are imported into this country, is that many of them are passed off on the public as indigo. Faked mixtures of alzarine, aniline and logwood are topped with a minute quantity of indigo, and often none at all, and sold as "indigo dyed." But that is not the worst; dealers and consumers having been told that indigotin is the sole colouring matter of indigo, they now will not buy any except upon its "indigotin content" test, and here there is room for an unlimited amount of fraud, as the test applied—viz., the potassium permanganate titration test—is essentially a false test, hence the party testing with it has unlimited scope for depreciating a proprietor's indigo, when he is *not* present; and when testing it for dealers and consumers the same objection exists. One of the most serious objections to this test is that the indigo is subjected to over seventy times its weight of fuming sulphuric acid, which utterly destroys its characteristic quality, its fastness, and the indigo having been converted into sulp-indigotic-acid, it can never be recovered as the same indigo again. But this is not all; Mr. W. P. Bloxam, B.Sc., who carried out research work at the Clothworkers' department of the University of Leeds for the Government of India some years ago, declared that "at no amount of dilution whatever was 1 c.c. of $\frac{N}{50}$ permanganate solution equivalent to 0·0015 gram of indigotin." Besides the above, the potassium permanganate is a very unstable compound, and requires to be constantly standardised, and indigos that test by it below 60 per cent. are often first-class vat indigoes. The most extraordinary thing is that neither chemists, brokers, dealers, buyers, nor consumers, have ever recommended the only true test for indigo as for all dyes, viz., the *dye test*. They will not employ it, but go on with the titration test, as they know that by it they can cheat the owners, whereas by the dye test they could not, as all honestly made indigoes dye very much alike, especially of the Bengal marks. I have got a lurking suspicion of the term "indigo blue." What is "indigo blue"? You can have a hundred shades of indigo blue, according to the percentage of indigo and rouses used on the cloth, and tradesmen call any blue they can sell, "indigo blue." Flour and sulphate of copper make a blue colour, which is often sold as a navy blue serge. "Synthetic indigotin" only dyes a sky blue, or china blue, and it is only when faked that it can approach natural indigo. I therefore hold that if "synthetic indigotin" is to be designated "indigo," and allowed to rank as a standard of indigo blue, it should be considered a gross injustice to the natural dye, and a great injury to hundreds of British subjects, who have been nearly ruined by these importations of fugitive and foreign dyes.

K. N. MacDonald, M.D.

ILLUMINATED MANUSCRIPTS.

I find that, speaking without preparation at the meeting on the 17th inst., I made the unpardonable blunder of describing the service of "Tenebrae," when talking of the "Exultet" Rolls of the eleventh to thirteenth centuries. They are connected with the service of the consecration and lighting of the Paschal candle on Easter Eve. The mistake, however, does not affect the point I raised as to the place these rolls hold in the history of the development of Italian art.

Robert Steele.

OBITUARY.

James Sewell Neville.—Mr. James Sewell Neville, of Sloley Hall, Norwich, died on the 16th inst., at the age of eighty-four. After being educated at Cambridge, he was called to the Bar in 1852. For some time he was Advocate-General of Bombay, and from 1876 to 1882 a Judge of the High Court of Judicature at Calcutta. He assumed, by Royal licence, the name of Neville in lieu of White in 1885. Mr. Neville joined the Royal Society of Arts in 1883; he served on the Council from 1896 to 1898, and on the Indian Section Committee from 1896 to 1901; and he took part in discussions on several occasions.

NOTES ON BOOKS.

A Dictionary of Applied Chemistry. By Sir Edward Thorpe, C.B., LL.D., F.R.S. Revised and enlarged Edition. Vol. I. London: Longmans, Green & Co. £2 5*s*. net per volume.

The new issue of Thorpe's "Dictionary of Applied Chemistry" is to consist of five royal octavo volumes, each of which is priced at £2 5*s*., and it is hoped that the whole work will be completed

Hosted by Google

within two years from the issue of the first volume, now under review.

In the first volume, which comprises 758 pages, and includes the alphabetical sequence as far as Chestnut Extract, there are many articles on important branches of applied chemistry, these articles being comprehensive, concisely worded, well up to date, suitably illustrated and furnished with references calculated to assist the reader in making further investigations. As examples of such admirable articles, may be mentioned that on Ammonia by Dr. Harold G. Colman, that on Bread by Dr. E. F. Armstrong, that on Brewing by Mr. John Heron, and that on Bromine by Dr. Rudolf Lessing.

As a contrast with the comprehensive articles mentioned above, there are others that are rather short, notably Dr. Robert Schüpphaus's article on Celluloid, which is comprised in less than a page, and is chiefly a reference to one American system of making and working a celluloid mass. There are no references to handbooks, papers, or patent specifications, no mention of film making or the various recent uses of liquid or semi-liquid preparations, and, as far as this article is concerned, amyl acetate, acetone, and some of the solvents that have been more or less recently introduced, might be non-existent. Another example of brevity is afforded by the four lines devoted to Salt Bittern. Considering the great present importance of bitterns as sources of magnesium compounds, bromine and iodine, a condensed tabular statement of the composition of the chief bitterns might have been given, or, failing this, a reference to some source of information, as for example the concise table on p. 220 of Ratton's "Handbook of Common Salt," or the more elaborate tables in the "Salz - bergbau und Salinkunde" of Fürer.

Other articles are perhaps somewhat overloaded with subjects that may be regarded as a trifle outside the legitimate scope of a work on applied chemistry, as for example two pages about Agate, the matter being mainly geological, but about one third of the article is devoted to details of the work of the lapidary. Another instance of what may perhaps be regarded as redundancy, is about five pages on the various methods of mechanically forming or moulding candles, and the extent to which the chemical is made to cede to the mechanical is well illustrated by the fact that it is considered worth while to give an illustration and special description of the well-known self-fitting candle with a truncated and fluted conical end; indeed, more than this, even the machine for moulding this form is described and figured.

Since the last edition of Thorpe's "Dictionary of Applied Chemistry" made its appearance, a new difficulty has arisen for those who are fated to compile chemico-technological works. The Sale of Goods Act of 1894 so far modified the old common law doctrine of implied warranty as to lay it down by statute law that in the case of a simple contract for the sale of a specific article under its patent or other trade name, there is no implied warranty as to its fitness for any particular purpose.

At any rate *post hoc*, and probably also to a great extent *propter hoc*, a host of special or trade names has arisen. For example, sodium perborate is now largely manufactured and is sold as a bleaching agent for laundry use. If a person purchases sodium perborate, there is an implied warranty that the material is fit for all uses for which sodium perborate is fit. As a matter of fact, sodium perborate is now sometimes sold under the trade or special name of "perborin," also as "perborin, M.," and possibly under a dozen other trade designations. By the statute referred to, such trade designations in themselves carry no warranty, although by express act or agreement a warranty may be associated with the trade term.

The editor of such a work as Thorpe's "Dictionary of Applied Chemistry" is confronted with the alternative of only using systematic and recognised names for substances, or of endeavouring to include the new special or trade terms. One may reasonably say "endeavouring," for to include all the trade terms as applied to chemicals and mixtures is obviously impossible, as trade terms appear and disappear, and also occasionally take new or modified meanings.

In the work before us, the attempt has been made to include trade terms. Thus, under the heading Antidiabetine we find this definition: "Trade term for a preparation said to be composed of saccharin and mannite." Antiseptine, we learn, "is said to be a mixture of zinc iodide, zinc sulphate, boric acid, and thymol." If it is the function of a work like that before us to publish a conjecture as to the composition of some proprietary medicines or preparations, it is difficult to see why others should not be included. Antigermin is included, and it is vaguely described as, "A preparation of a copper salt of a weak organic acid mixed with lime." The next following article is on Antihypo, and this is said to be, "A solution of potassium percarbonate, used for destroying sodium thiosulphate in photographic negatives and prints." It is difficult to see how this can be correct, as the solution of potassium percarbonate decomposes with effervescence spontaneously at the ordinary temperature. The use of the solid potassium percarbonate, added to the wash water, is known to every photographer. Pages might be filled with comments on the special or trade names, and the uncertain, shifting, or unsatisfactory nature of the available information.

The new edition of Sir Edward Thorpe's "Dictionary of Applied Chemistry" should take a place among the technological classics of the time, and doubtless it will be much sought after as a book of reference in public libraries. At the same time, in compiling the volumes to come, it may be well to remember that the special article of an eminent contributor may sometimes require

Hosted by Google

pruning and sometimes supplementing; further, a watchful and careful sub-editing, if practicable by one individual, may be an important factor if trade designations and proprietary medicaments are to be included.

GENERAL NOTES.

Professor Boys's Juvenile Lectures.—Mr. Carmichael Thomas, on behalf of the proprietors of the *Graphic*, has presented to the Society the original of the drawing by Mr. Arthur Garratt of Mr. Charles Vernon Boys, F.R.S., delivering a juvenile lecture on "Soap Bubbles" at the Royal Society of Arts. The picture appeared as a full-page illustration in the *Graphic* of January 20th, 1912.

Ancient Workers in Copper.—In the course of his inaugural address, as President of the Institute of Metals, Professor William Gowland, F.R.S., spoke of the early history of copper and its alloys. He said so momentous a discovery as that of metals contained in ores must have had its origin in the domestic fires of the Neolithic Age. The camp fire was, in fact, the first metallurgical furnace, and from it, by successive modifications, the huge furnaces of the present day had been gradually evolved. Furnaces of primitive form survived in Derbyshire up to the seventeenth century. In Japan the furnace for smelting copper, tin, and lead ores, which was a mere hole in the ground, was in universal use there up to 1858, and was still extensively employed. It was as simple as that of the Bronze Age. There was abundant evidence to show that Egypt was the first in the field in artistic bronze casting. The fall of Greece and the rise of the supremacy of Rome was the dawn of an important period in the history of copper and its alloys. In Spain and in Britain copper-smelting was vigorously carried on by the Romans. The Romans were the first makers of brass. Although they were unacquainted with the essential constituent, zinc, yet they discovered that, by melting copper altogether with a certain ore (calamine), a yellow alloy of a more golden colour than bronze could be obtained. The process was so effective that, until a comparatively recent period, all brass was made in Europe by the ancient process, and even until a few years before 1861 it was thus made in Birmingham. The survival of this ancient process afforded a striking example of the conservatism characteristic of British metallurgy. With the disappearance of the calamine brass, one of the last links in the chain connecting the modern metallurgy of copper and its alloys with antiquity was broken. An important link, however, still remained in the process *à cire perdue* of casting bronze, a process in which it could hardly be said that we were any further advanced than the Greek founders of some centuries before our era. Further, it should not be overlooked that the principles on which copper refining is based were carried out in practice in the time of Pliny.

Photographic Exhibition.—A collection of pictorial photographs is now on view, and will remain open till February 24th, at the house of the Royal Photographic Society, 35, Russell Square. Admission is free to the public on presentation of visiting card. The photographs are by members of societies affiliated to the Royal Photographic Society, and have been selected as being the best work produced by each society.

Consumption of Algerian Grapes in Paris.—The *Bulletin du Gouvernement général de l'Algérie* states that the total quantity of grapes grown in that colony and sold last season at the Halles Centrales of Paris amounted to 1,113,000 kilograms (2,254,165 lbs.) as compared with 1,157,180 kilograms (2,551,582 lbs.) in 1910. At the commencement of the season which lasted from July 13th to August 14th, the first consignments (which were small) realised between 2 francs and 2·40 per kilogram (9*d*. to 11*d*. per lb.), whilst the prices towards the end of the season ranged from 20 to 60 cents per kilogram (less than 1*d*. to 2¾*d*. per lb.). The largest quantity sold on any single day was 74,940 kilograms (165,241 lbs.).

Silk Production in Italy.—The Italian cocoon crop of 1910 amounted to 22,658,000 pounds as compared with 21,870,000 pounds in 1909 and 27,933,000 pounds in 1908. The crop of Piedmont in 1910 was a little over 10 million pounds as against 9 millions in 1909, and 15 millions in 1908. In 1910, as in 1909, Piedmont, instead of producing, as usual, more than one half of the total Italian crop, produced so small a quantity as greatly to diminish the total crop of Italy. The failure of the Piedmontese crop was due in part to the cold and rainy weather of the spring months which affected the growth of mulberry leaves, and in part to the *Diaspis pentagona*, which made its appearance early in the spring and caused considerable damage. The quality of the crop was, however, satisfactory, and was richer in silk than the crop of 1909.

The Aerial Fleet of Germany.—The largest fleet of dirigibles in Europe at the present time is that of Germany, which numbers seventeen. Of these, eleven belong to the army, and six are private. There are also nine more in course of construction, so that by the spring Germany will have a fleet of twenty-six of these airships—a number greater than those possessed by all the other European Powers together. The number of dirigibles owned by France is ten, by Russia five, Austria-Hungary four, Spain and Italy two each.

Mussel Mud as a Fertiliser in Canada.—In most of the bays indenting the shores of Prince Edward Island are found extensive deposits of mussel mud, so called locally, being organic

Hosted by Google

remains of countless generations of oysters, mussels clams, and other shell-fish. The shells, usually more or less intact, are found embedded in dense deposits of a mud-like substance, and this combination is a fertiliser of high value and potency. It supplies lime and organic matter, besides small quantities of phosphates and alkalies. An ordinary dressing of it secures fertility in a striking manner to the poorest or most exhausted soil. The shells decay slowly, year by year, throwing off a film of fertilising stuffs. The deposits round Prince Edward Island vary from five to twenty-five feet in depth. They are taken up by dredging machines, worked from rafts in summer or from the ice in winter.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings, at 8 o'clock:—

January 31.—Professor G. W. Osborn Howe, M.Sc., M.I.E.E., "Recent Progress in Radio-Telegraphy." Sir William H. White, K.C.B., F.R.S., will preside.

February 7.—Leonard Hill, M.B., F.R.S., and Martin Flack, M.A., M.B., B.Ch., "The Influence of Ozone in Ventilation."

February 14.—Cecil Thomas, "Gem Engraving." Sir Arthur John Evans, D.Litt., LL.D., F.R.S., will preside.

February 21.—Frank Warner, "Silk." Sir George Birdwood, K.C.I.E., C.S.I., M.D., LL.D., will preside.

February 28.—H. A. Roberts, M.A., "The Relations of Science to Commerce and Industry." Principal Sir Henry A. Miers, M.A., D.Sc., F.R.S., will preside.

Indian Section.

Thursday afternoons, at 4.30 o'clock:—

February 8.—Colonel Sir Thomas H. Holdich, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc., "The North-East Frontier of India." Sir Frederic W. R. Fryer, K.C.S.I., formerly Lieutenant-Governor of Burma, will preside.

March 14.—E. A. Gait, I.C.S., C.I.E., Census Commissioner for India, "The Indian Census of 1911."

April 25.—Walter Saise, D.Sc., M.Inst.C.E., Hon. Member Institute of Mining and Geology, India, A.R.S.M., V.D., "The Coal Industry and Colliery Population of Bengal."

May 16.—Neville Priestley, Managing Director, South Indian Railway, "Indian Railways."

Colonial Section.

Tuesday afternoons, at 4.30 o'clock:—

January 30.—W. A. Legg, M.Inst.C.E., late Supervising Engineer, Irrigation Department, Cape Colony, "Irrigation in South Africa." The Hon. Sir Richard Solomon, G.C.M.G., K.C.B., K.C.V.O., K.C., High Commissioner for the Union of South Africa, will preside.

May 7.—Alan Burgoyne, M.P., "Colonial Vine Culture."

May 21.—The Hon. J. G. Jenkins, "Australian Railways."

Cantor Lectures.

Monday evenings, at 8 o'clock:

Vaughan Cornish, D.Sc., F.G.S., F.C.S., "Ocean Waves, Sea-Beaches, and Sandbanks." Two Lectures.

Syllabus.

Lecture II.—January 29.—The action of waves and tidal currents on sea-beaches and sandbanks—The proper action of waves to drive sand and shingle shoreward—The proper action of waves to drive mud seaward—Special conditions under which the action on sand is reversed—The proper action of the tide to drive shingle in the direction of the flood—The normal removal of shingle from promontories and its accumulation in bays—The exceptional accumulation of shingle in salient positions, *e.g.*, at Dungeness—Groynes—The reason of the graded arrangement of shingle on the Chesil beach—The formation of a sandbank on the up-channel side of a promontory—Sandbanks in estuaries and their arrangement by tidal currents—Their rippled surface as a means of mapping these currents—Their influence on the formation of tidal bores—The struggle between land water and tidal water to arrange the sandbanks in the Severn—The variability of the Severn Bore as determined by these factors—The circumstances which determine the starting point of the Severn Bore.

Loudon M. Douglas, F.R.S.E., "The Meat Industry." Three Lectures.

Syllabus.

Lecture I.—February 5.—The Bullock and its Products.

Lecture II.—February 12.—The Sheep and its Products.

Lecture III.—February 19.—The Pig and its Products.

Luther Hooper, "The Loom and Spindle: Past, Present, and Future." Three Lectures.

February 26, March 4, 11.

Hosted by Google

NOEL HEATON, B.Sc., F.C.S., "Materials and Methods of Decorative Painting." Three Lectures.

March 18, 25, April 1.

HOWARD LECTURES.

Monday evenings, at 8 o'clock:—

CAPTAIN H. R. SANKEY, R.E., M.Inst.C.E., "Heavy Oil Engines." Four Lectures.

April 29, May 6, 13, 20.

Dates to be hereafter announced:—

F. MARTIN DUNCAN, "The Work of the Marine Biological Association."

JOHN NISBET, D.Oec., late Conservator of Forests, Burma, "The World's Decreasing Timber Supplies."

CHARLES C. ALLOM, "The Development of Artistic Skill in the Applied Arts."

ERNEST KILBURN SCOTT, Assoc.M.Inst.C.E., M.I.E.E., "The Manufacture of Nitrates from the Atmosphere."

CHARLES BRIGHT, F.R.S.E., M.Inst.C.E., M.I.E.E., "The Administration of Imperial Telegraphs."

HAROLD COX, "The Interdependence of Morals and Economics."

E. D. MOREL, "British Rule in Nigeria."

GORDON CRAIG, "Art of the Theatre." MISS ELLEN TERRY will preside.

THEODORE E. SALVESEN, "The Whaling Industry of To-day."

PROFESSOR ERNEST A. GARDNER, M.A., "Greek Sculpture."

GEORGE FLETCHER, "Technical Education in Ireland."

MEETINGS FOR THE ENSUING WEEK.

MONDAY, JANUARY 29...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Dr. Vaughan Cornish, "Ocean Waves, Sea-Beaches and Sandbanks." (Lecture II.)

Farmers' Club, Whitehall Rooms, Whitehall-place, S.W., 4 p.m. Mr. J. C Newsham, "Farm Institutes in Relation to Agricultural Education."

Geographical, Burlington-gardens, W., 8.30 p.m. Professor Norman Collie, "Explorations in the Canadian Rockies."

Actuaries, Staples Inn Hall, Holborn, W.C., 5 p.m. Mr. G. E. May, "The Investment of Life Assurance Funds."

London Institution, Finsbury-circus, E.C., 5 p.m. Professor Sir Walter Raleigh, "The Writings of Sir George Savile, Marquis of Halifax."

Architectural Association, 18, Tufton-street, S.W., 7.30 p.m. Mr. A. G. R. Mackenzie, "That Modern House-Planning tends to be Over-elaborate."

TUESDAY, JANUARY 30...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Colonial Section.) Mr. W. A. Legg, "Irrigation in South Africa."

Sociological, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8.15 p.m. Captain A. St. John, "The Community and its Children: their Co-operation in their own Training."

Royal Institution, Albemarle-street, W., 3 p.m. Professor W. Bateson, "The Study of Genetics." (Lecture III.)

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Mr. R. J. Durley, "The Central Heating- and Power-Plant of McGill University, Montreal."

Photographic, 35, Russell-square, W.C., 8 p.m. Mr. J. McIntosh, "Sylvan Essex; its Bye-ways and Water-ways."

WEDNESDAY, JANUARY 31...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Professor G. W. Osborn Howe, "Recent Progress in Radio-Telegraphy."

King's College, Strand, W.C., 5 p.m. Dr. J. Paul Richter, "The Art of the Catacombs."

Sanitary Engineers, Caxton Hall, Westminster, S.W., 8 p.m. Presidential Address by Mr. A. J. Martin.

Automobile Engineers, Connaught Rooms, Great Queen-street, W.C., 8 p.m. Discussion on "Self-Starters for Internal-Combustion Engines."

East India Association, Caxton Hall, Westminster, S.W., 4.15 p.m. Mr. H. G. Keene, "Home Rule for India."

THURSDAY, FEBRUARY 1...Royal, Burlington House, W., 4.30 p.m.

Antiquaries, Burlington House, W., 8.30 p.m.

Linnean, Burlington House, W., 8 p.m. 1. Professor A. Forel, "Fourmis des Seychelles reçues de M. Hugh Scott." 2. Mr. F. W. Edwards, "Tipulidæ from the Indian Ocean." 3. Dr. Gunther Enderlein, "Sciaridæ, mit einem Anhang von Dr. J. J. Kieffer (Beschreibung neuer Sciariden von den Seychellen Inseln)." 4. Mr. C. Morley, "Ichneumonidæ from the Indian Ocean." 5. Mr. C. Tate Regan, "New Fishes from Aldabra and Assumption, collected by Mr. J. C. F. Fryer."

Chemical, Burlington House, W., 8.30 p.m. 1. Messrs. F. Tutin and H. W. B. Clewer, "The Constituents of Commercial Chrysarobin." 2. Messrs. R. L. Taylor and C. Bostock, "Researches on Bleaching Powder. Part. II.—The Action of Dilute Acids on Bleaching Powder." 3. Mr. H. Hibbert, "The Quantitative Estimation of Hydroxy-, Amino-, and Imino-Derivatives of Organic Compounds by means of the Grignard Reagent, and the Nature of the Changes taking place in Solution." 4. Mr. A. C. Dunningham, "An exact Investigation of the three component system—Sodium Oxide, Acetic Anhydride, Water."

London Institution, Finsbury-circus, E.C., 6 p.m. Mr. M. Greenwood, "Plague—its Origin and History."

Royal Institution, Albemarle-street, W., 3 p.m. Professor A. M. Worthington, "The Phenomena of Splashes." (Lecture I.)

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Dr. Vaughan Cornish, "The Panama Canal."

FRIDAY, FEBRUARY 2...Royal Institution, Albemarle-street, W., 9 p.m. Sir James Mackenzie Davidson, "Vital Effects of Radium and other Rays."

Civil Engineers, 25, Great George-street, S.W., 8 p.m. (Students' Meeting.) Captain H. R. Sankey, "Steam Turbines: Some Practical Applications of Theory." (Lecture I.)

SATURDAY, FEBRUARY 3...North-East Coast Institute of Engineers and Shipbuilders, Technical College, Sunderland, 7.30 p.m. (Graduates' Section.) Mr. F. W. Dugdale, "The Growth of the Steam-Engine."

Royal Institution, Albemarle-street, W., 3 p.m. Sir Alexander C. Mackenzie, "Russian Music of To-Day."

Hosted by Google

Journal of the Royal Society of Arts.

No. 3,089. VOL. LX.

FRIDAY, FEBRUARY 2, 1912.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, FEBRUARY 5th, 8 p.m. (Cantor Lecture.) LOUDON M. DOUGLAS, F.R.S.E., "The Meat Industry." (Lecture I.)

WEDNESDAY, FEBRUARY 7th, 8 p.m. (Ordinary Meeting.) LEONARD HILL, M.B., F.R.S., and MARTIN FLACK, M.A., M.B., B.Ch., "The Influence of Ozone in Ventilation." LORD SANDERSON, G.C.B., K.C.M.G., Chairman of the Council, will preside.

THURSDAY, FEBRUARY 8th, 4.30 p.m. (Indian Section.) COLONEL SIR THOMAS H. HOLDICH, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc., "The North-Eastern Frontier of India." SIR FREDERIC W. R. FRYER, K.C.S.I., formerly Lieutenant-Governor of Burma, will preside.

Further details of the Society's meetings will be found at the end of this number.

CANTOR LECTURE.

On Monday evening, January 29th, MR. VAUGHAN CORNISH, D.Sc., F.G.S., F.C.S., delivered the second and final lecture of his course on "Ocean Waves, Sea-Beaches, and Sandbanks."

On the motion of the Chairman a vote of thanks was accorded to Dr. Vaughan Cornish for his interesting course.

The lectures will be published in the *Journal* during the summer recess.

COLONIAL SECTION.

Tuesday afternoon, January 30th; the HON. SIR RICHARD SOLOMON, G.C.M.G., K.C.B., K.C.V.O., K.C., High Commissioner for the Union of South Africa, in the chair. A paper on "Irrigation in South Africa" was read by MR. W. A. LEGG, M.Inst.C.E., late Supervising Engineer, Irrigation Department, Cape Colony.

The paper and discussion will be published in a subsequent number of the *Journal.*

PROCEEDINGS OF THE SOCIETY.

INDIAN SECTION.

A meeting of the Indian Section was held on January 18th, 1912. In the unavoidable absence of Sir James A. Bourdillon, K.C.S.I., SIR KRISHNA GOVINDA GUPTA, K.C.S.I., occupied the chair.

The paper read was—

THE OLD DISTRICT RECORDS OF BENGAL.

By the REV. WALTER K. FIRMINGER, B.D.,
Senior Chaplain, H.M.'s Bengal Establishment.

In nearly all of the older chief Government offices of the districts of Bengal there are to be found presses containing records of the British administration of the several districts, and these travel back in age frequently to the days of Warren Hastings, and in at least two instances to those of Lord Clive. Of these rural records, their character, their present condition, and their value as materials for history, it is my privilege to speak this evening. Sir William Hunter, in his charming way, has thus described these collections: "They consist of reports, letters, minutes, judicial proceedings, and relate, in the words of eye-witnesses, and with official accuracy, the daily history of the country from the time the English took the administration into their own hands. Many of them are written in the curt, forcible language which men use in moments of excitement or peril; and, in spite of the blunders of copyists and the ravages of decay, they have about them that air of real life which proceeds not from literary ability, but from the fact that their authors' minds were full of the subjects on which they wrote. We learn from these worm-eaten manuscripts that what we have been accustomed to regard as Indian history is a chronicle of events which hardly affected, and which were for the most

Hosted by Google

part unknown to, the contemporary mass of the Indian people. On their discoloured pages the conspicuous vicissitudes and revolutions of the past (*i.e.*, the eighteenth) century have left no trace. Dynasties struggled and fell, but the bulk of the people evinced neither sympathy nor surprise, nor did the pulse of village life in Bengal move a single beat faster for all the calamities and panics of the outside world. But these volumes, so silent on subjects about which we are already well informed, speak at length, and with the utmost precision, on matters regarding which the Western world is profoundly ignorant. They depict in vivid colours the state of rural India when the sceptre departed from the Mussulman race. They disclose the complicated evils that rendered our accession for some time an aggravation rather than a mitigation of the sufferings of the people. They unfold one after another the misapprehensions and disastrous vacillations amid which our first solid progress was made. They impartially retain the evidence of low motives and official incompetence side by side with the impress of rare devotion and administrative skill. But, taken as a whole, they reveal the secret of England's greatness in the East. They exhibit a small band of our countrymen going forth to govern an unexplored and a half-subdued territory. Before the grave heroism and masterful character of these men, the native mind succumbed. Our troops originated for us a rude Mahratta-like supremacy; but the rural records attest that the permanent sources of the English ascendency in Bengal have been, not their brilliant military successes, but deliberate civil courage and indomitable will."*

In this passage, Sir William Hunter has shown far more graphically than I could do in words of mine own, what is the real interest of the old Collectorate records, and I venture to think you will agree with me that the passage I have quoted is of peculiar interest, when we remember that Sir William Hunter's "Annals of Rural Bengal" was published, and in four months passed through three editions, in 1868—nearly six years before the publication of John Richard Green's "Short History of the English People." It is surely not too much to say that Hunter, in the "Annals," applied to Indian history that conception of the history of a people or peoples which at a later date made Green's "Short History" mark an epoch in historical science. No doubt some of the details of Sir William's statement which I have quoted are open to dispute; but the passage, as a whole, affords a clear view of the general nature of the records we are concerned with this evening.

* Hunter, "Annals of Rural Bengal," pp. 7, 8.

On an earlier page, Sir William tells us how he made his first acquaintance with these district records he so skilfully employed in the making of his book. "In taking over charge of the District Treasury," he writes, "I was struck with the appearance of an ancient press, which, from the state of its padlocks, seemed not to have been opened for many years, and with whose contents none of the native officials were acquainted. On being broken open, it was found to contain the early records of the district from within a year of the time that it passed directly under British rule. The volumes presented every appearance of age and decay; their yellow-stained margins were deeply eaten into by insects, their outer pages crumbled to pieces under the most tender handling, and of some the sole palpable remains were chips of paper mingled with the granular dust that white ants leave behind. Careful research has convinced me that these neglected heaps contain much that is worthy of being preserved. For what trustworthy account have we of the real state of India at the commencement and during the early stages of our rule? Eloquent and elaborate narratives have indeed been written of the British ascendency in the East; but such narratives are records of the English Government, or biographies of the English Governors of India, not histories of the Indian people. The silent millions who bear our yoke have found no annalist."*

Here, again, I find in Sir William's book far better words than I could supply to describe the actual condition of a great part of the records. "Yellow-stained margins," "pages crumbling to pieces under the most tender handling," "chips of paper mingled with the granular dust that white ants leave behind"—of all these I had a liberal experience when the precious Midnapur Records were entrusted for a short time to my care for purposes of research. In 1904, Mr. A. P. Muddiman, I.C.S., had made an examination of these particular records, and then he wrote: "The original letters, if kept any longer in their present form, will crumble to dust almost at once. They are of various sizes and shapes, and are bound up with particular care. Many are torn, and every time the volume is opened they are bound to be damaged. Torn pieces of the letters are simply placed in the volume hap-

hazard, and are exceedingly liable to be lost." Of six volumes of letters received, dated respectively 1764, 1765, 1766, 1767, 1768, 1769, I was only able to see the last five, and these were in reality no longer bound volumes, but heaps of decaying paper tied up between boards, the original stiffening of the covers, with leaves overlapping and breaking off at touch. Before venturing to read the papers, I sought and obtained the permission of the Bengal Government to detach each letter from its heap and place it in a separate paper cover, on which the date and a *précis* of its contents could be written. Having done this, I proceeded to make a copy of the letters, inserting in due place copies of letters from a large and dilapidated volume of letters received.* Some 200 of these letters, chiefly those relating to military expeditions in the jungles to the west of Midnapur, were published, by kind permission of the Government of Bengal, in "Bengal: Past and Present," the organ of the now dying Calcutta Historical Society.

It must not, however, be inferred that the work of recovering these venerable records for purposes of historical science in every case necessitates these difficult and, for the private student, costly operations. At Sylhet, for instance, I found that the oldest records were in a far more legible condition than copies made from them in comparatively recent years by a Collector (E. J. Barwell), who wisely held that the old papers, although themselves not originals but copies, were worthy of editing and publication. Our great-grandparents in Bengal were exceedingly fortunate in the ink they employed; their early training included the art of beautiful writing, and the foolish fashion of unintelligible signatures was practically non-existent. Age in itself does not account for the decay of papers, even in Bengal.† The preservation of records in Eastern India depends mainly on the nature of the paper—its capacity or non-capacity for resisting damp, the height which bound volumes are kept from the ground, the access which is granted to readers at the record rooms, and many other circumstances quite independent of antiquity. It must be remembered, especially when the word "neglect" is employed, that a volume, which for centuries has remained fair and legible, may, despite the watchfulness of ages, be ruined in a single night by insects or by mice. In the new Province of East Bengal and Assam, the great earthquake of 1897 dealt harsh measure to the record rooms, and yet, after remaining exposed to the elements—in circumstances in which care for paper would have been a somewhat cynical disregard for humanity—there are heaps of precious historical records which have passed through the ordeal unobliterated. Will our feebly printed flimsy typewritten papers compete in antiquity with the brave paper and virile ink of the eighteenth century?

The difficulty of dealing with these old manuscripts on account of their decay is often surpassed by the difficulties created by the well-intentioned attempts to copy perishing records, or to arrange the whole series in classified order. When copying has had to be done, the work has usually been assigned to native clerks, and the evil is not that they have been careless, but that they have tried to do their work too well. When the native copyist is in difficulty about the spelling of a word, he invariably gives a word he does happen to know, instead of the spelling which puzzles him. The compositor of the Clarendon Press tries to set up in type what the author actually wrote; the Bengali's preoccupation is to set up what he thinks his European employer must have intended. Then as to classification. It is the very endeavour to be excellent which has produced the most perplexing results. Where the editing Collector has ordered a strict adherence to chronology, the work of dealing with his records is fairly easy; but where he has ordered his *duftri*, or binding clerk, to sort the letters and bind them under separate headings, the result is simply lamentable. In some districts one finds that the letters have been bound together in order of date; in others there is an attempt to classify them; and in no case that I know of has the principle of the classification been consistently adhered to. Suppose, for instance, the editing Collector has endeavoured to keep all letters relative to sericulture in a volume labelled "Commercial," you will probably find that the most important letter on mulberry trees has been bound up in correspondence with the Board of Revenue on matters of land revenue. There is only one way, in my opinion, of obviating

* This copy-book was made in the early part of the nineteenth century, by order of the then Collector, Mr. E. J. Barwell, son of the famous colleague of Warren Hastings. Richmond Thackeray, father of the novelist, was acting judge at Midnapur in 1811.

† As an example of this I may mention that in 1906 I discovered the long lost MS. of Father Anthony Monserrate's (S.J.) "Mongolicae Legationis Commentarius" in a heap of decayed and mostly worthless books in St. Paul's Cathedral Library, Calcutta. The book was completed in January, 1591, while the author was in prison at Sana in Arabia. Its penmanship calls for the services of an expert, but the MS. itself is uninjured by age and rough treatment.

Hosted by Google

this difficulty. The letters must be rebound and placed, as I placed the Midnapur letters, in separate covers. The work of classification should be left to the compiler of an index.

The graphic passages I have quoted from Sir William Hunter must not, however, mislead us. The greater part of the Bengal District records are not so terribly decayed, although the decay of the remaining portion has gone very far. And it must not be thought that all the papers are of intense interest. Whole volumes may contain nothing more than the minutes of elaborate inquiries into the local peculiarities of the land-measuring rod, or the petty expenses of a police-court. In dealing with records to be used as materials for history, I would plead that it is unsafe to allow any single person to distinguish between what is important and what is not important, and to print and publish what he approves of, and turn over to oblivion what he rejects. The records of which I am speaking, belong respectively to the Revenue Department of the two Bengal Governments, and it is probable that, while the professional revenue administrator would value them for the light they throw on the history of his science, the student of social and economic history would attach a value to papers which, from the narrower point of view, seem to be unworthy of preservation. Even merely covering letters have their value, because they sometimes reveal the names of ancient offices and their holders.

I have said that nearly every chief district office has its collection of historical records, but it must not be assumed that all the local records are to be found at the head district office. When one comes to examine the record rooms, one discovers almost at once that the series of volumes are not complete, and, because there are no records for certain years in the place itself, it is natural to conjecture that the missing records either have been lost or have perished. In some cases the conjecture is sound. In the early days the Collectors, or Supervisors as they were first called, appear to have regarded the records as their own personal property, and to have taken them home with them on their retirement. That remarkable person, the Hon. Robert Lindsay, for instance, left a large collection of correspondence behind him at Sylhet, but I understand from his descendant, Lord Balcarres, that the records of Lindsay's judicial work are in the possession of the family. On leaving Sylhet in 1775, William Makepeace Thackeray, the novelist's grandfather, brought away the Sylhet records of his time, and deposited them at Dacca, where, for the present at least, they are lost.* Missing volumes are often due to the fact that at different periods the Collector was in charge of two districts at one time, and either the records of the two stations have been mixed with each other, or at one station will be found volumes of correspondence which really belong to another. Let me give an instance of the difficulties created in this way.

In 1873 Mr. F. G. Glazier, a revenue official of long experience, published an historical account of the Rangpur district, based on the records preserved at Rangpur. In this treatise Mr. Glazier occasionally speaks of breaks in the records, and he seems to have thought that these breaks were due to the volumes having either perished or been removed and lost. Now one break in the local records of Rangpur would be accounted for by the fact that in 1773 the European Collectors were temporarily recalled from the districts, and six Provincial Councils of Revenue were established. Under this system the records of the Provincial Council of Dinajpur ought to supply what is wanting for Rangpur, and these, with the exception of a few stray volumes, are to be found in the Bengal Secretariat record room at Calcutta. In going through the Dinajpur records, I found numbers of papers really belonging to Rangpur, and the explanation of this was that at one time both Collectorates were under a single individual. Of Mr. Westland's oversight of early Jessore records I have written in a footnote to this paper.

Let me give another and perhaps a more striking instance. Mr. Glazier, in his treatise, only just touches upon the subject of a serious insurrection which arose in the Rangpur District as the result of the oppressive measures adopted by the Diwan—Raja Debi Sinh. Mr. Glazier must have forgotten the story of Warren Hastings's impeachment, or he would have been at pains to tell us more about the Raja and his doings. You will remember how, in his great *coup de théâtre*, the opening speech at the Hastings trial, Burke spoke of "Devi Sing, one of the most shocking monsters that ever stained the page of history." It was the

* Mr. F. Bradley Birt has recently published a life of "Sylhet Thackeray," and has shown that where the Sylhet archives fail, those of the Board of Revenue at Calcutta wil often avail. I think Mr. Bradley Birt misleads us by describing Thackeray as "Collector of Sylhet." Sylhet was entirely dependent on Dacca at the time, while the "Collectors" were dependent on Murshidabad. Mr. Bradley Birt's book is of immense interest, and is very thoroughly done.

Hosted by Google

recitation of the cruelties committed by this supposed creature of Hastings which made Fanny Burney tremble for her hero, while the other ladies who heard Burke and witnessed his dramatic gestures, swooned; and the great orator himself "was seized with a cramp in his stomach and was disabled from going on." The Managers, as we know, refrained from placing the misdoings of "Davy Sing" in the charges, because to do so would have enabled the defendant to expose the shallow basis of their allegations. There is enough in the history of the Hastings trial to reveal the utter shamelessness of the Managers in their attempt to fasten the alleged enormities of the Raja on the Governor-General, but the records we need in order to get at the whole story of Raja Debi Sinh and the Rangpur disturbances are to be found in seven volumes of the Commission's Proceedings, and these volumes are kept, not at Rangpur, but in the Bengal Secretariat Library, while the final report, discovered by Mr. Muddiman at Dacca, is now at Shillong, where I have had it copied for inclusion in my forthcoming edition of the Rangpur records. I mention this as an instance of the way in which the local records get dispersed, and it shows how easy it is, in existing circumstances, to despair of sources of information when they are not to be found in the local record room at which we should expect to find them.

I cannot, while the subject of the Rangpur records is suggested to us, pass on without saying just a word about the great interest they possess. One of the earliest Collectors was George Bogle, the friend of Hastings, known to wider fame as the traveller to Tibet. Another is Peter Moore, the friend and patron of Richard Brinsley Sheridan, the uncle and guardian of William Makepeace Thackeray, the novelist. Moore was a hostile witness at the Hastings trial, and another Rangpur Collector, Charles Purling—the negotiator of a treaty with Cooch Behar, Chief at Dacca, and Resident at Lucknow—was heard in the great pro-Consul's favour. Rangpur was, in the eighteenth century, essentially a frontier province, and from its records we learn something of the earliest pioneers of British trade on the waters of the mysterious Brahmaputra. We find Hastings writing in trepidation to have one George Lear prevented from "waging war in Assam"; and at one time we find the whole trade with Assam granted as a private monopoly to a Mr. David Killican. The records often touch very closely on the personal life and occupations of the writers—their fevers, their gardens, their homes, the little presents of wild animals, joints of meat, and bottles of Madeira. We hear of immense undertakings to tie down the erratic rivers to orthodox courses, and curious stories about the tricks of native merchants to turn the currency of coin in their favour. Perhaps the most interesting feature of all are the fine attempts recorded on the part of the Company's commercial agents to protect their weavers from the rapacity of the native subordinate revenue officers. The Rangpur and Dinajpur archives contain letters from Charles Grant (the father of Lord Glenelg and Sir R. Grant), to whose wise and enlightened philanthropy Bengal owes so much; from G. Udney, the protector of the great Dr. Carey; or from Creighton, the "discoverer of Gaur."

I must now pass on to discuss in general terms the essential value of these District Records as materials for history. I am afraid I have a very ill-sounding doctrine to deliver, and it is this: The history of revenue administration is the backbone of the history of Bengal under English rule. It seems to me absolutely impossible to construct the history of the English in Bengal unless you realise this plain but unwelcome truth. Neither Plassey nor Buxar was fought to win territorial sovereignty for the East India Company or for the British Crown. Our battles in Bengal were fought in order to maintain on the Musnud of Murshidabad a ruler powerless to uproot the English factories, and, as the presence of an army was continually necessary to keep on the throne the kind of ruler required to secure the commercial interests of the English Company, it became desirable that the military force behind the Nawab should be a British one. To maintain this army the English were granted land revenue, and it was essentially as revenue collectors that the English entered into the real occupation of rural Bengal. In 1765 the grant of the Diwani was made to the Company, and although when informed of this acquisition the Court of Directors endeavoured to limit their new possession to the bare receipt of the revenue, yet, as many indeed saw at the time, the Diwani, in the hands of those who had the military supremacy, was bound to absorb the Nizamat from which it was, in theory, separated. I am not going to discuss the ancient question, "Is the State the owner of all the land in India?" It is enough to say that that once much-debated question turns on a mistaken application of Western ideas of ownership to an Eastern world; but that such a question would have been

Hosted by Google

answered in the affirmative by Verelst * certainly, and Hastings most probably, in itself shows how prevalent land revenue administration must be in the pages of a really authentic history of Bengal under British rule.

Lord Macaulay has said in his Essay on Warren Hastings, that up to 1772 "the only branch of politics about which the English functionaries busied themselves was negotiation with the native princes. The police, the administration of justice, the maintenance of order, were left to this high functionary"—*i.e.*, the Naib Diwan at Murshidabad. Mr. Westland, in his work on Jessore, goes further, and says: "I am aware that direct government is usually dated from 1772, but what the British did before 1781 can hardly be dignified by the name of internal administration." I fancy the view expressed by Macaulay represents received opinion, but I cannot conceive that it can be reconciled with the state of things revealed by the District Records.

The idea that before 1772 the English had little or no concern with revenue affairs is, I think, due to the fact that it is so often ignored that the revenue of the important districts of Burdwan, Midnapur, and Chittagong, came to the hands of the English by treaty with Mir Kasim in September, 1760, five years before the grant of the Diwani. These districts are known as the "Ceded lands," in distinction to the "Diwani portion," or remaining portion of Bengal, the revenues of which came to the Company on certain conditions in 1765. In 1765 the revenue yielded by the Ceded lands, together with the Calcutta lands, amounted to about £593,717, and that of the Diwani portion to about £1,088,718; so it cannot be thought that the revenue of the ceded districts was a matter of so little importance that it may be regarded as a negligible quantity. Let us for a moment glance at what the District Records have to reveal on the subject of the Ceded lands.

Burdwan has no local records, at least not at Burdwan itself, prior to 1786, but a good deal of the history of the district between 1760 and 1772 may be gathered from Verelst's "View of the Rise, Progress, and State of the English Government in Bengal" (1772), and from the reports of the Parliamentary Committee in 1773. Midnapur has records from 1764 onwards. The Chittagong records commence with the arrival of an English Chief and Council in 1760, but there are lengthy breaks in the series, volumes having been reported as lost in the time of Warren Hastings's governorship. Now, the records of Midnapur and Chittagong show that from the very first the English assumed the direct management of the revenues, and with this went the administration of civil justice and the police control of the country. Burdwan, from 1760 onwards, received very special attention.

It must also be recalled to memory that from November, 1698, the Company had been zamindar or talukdar of the three towns which form the nucleus of modern Calcutta. In 1757 the Company became zamindars of the important district known as the Twenty-four Parganas, which in the year May, 1758—April, 1759, realised in revenue £57,996, rising in 1760-1 to £110,418. I have not time to show you that, although the method of raising the revenue usually adopted was to farm it out to speculators, the Company's servants, as a matter of fact, had not only obtained, before 1772, a very considerable acquaintance with revenue affairs, but had intervened with marked results in the police of the country, and in the important Ceded lands and Calcutta lands had taken nearly every step to realising territorial sovereignty, save that of reforming an iniquitous administration of criminal justice. It was in the matter of judicature in criminal cases that English energy held fire, and even in this respect I believe that our ancestors in Bengal did far more in the direction of humane method during this difficult period of confused theory than the theory on which their occupation was based could justify. In a brief paper, as the present must be, I cannot hope to marshal even a third of the arguments which these old records afford, to destroy that pernicious view of the origin of the English Empire in India which Macaulay's genius has popularised in prose, and of which Rudyard Kipling is poet laureate:—

"Once, two hundred years ago, the trader came,
 Meek and tame.
Where his timid foot first halted, there he stayed,
 Till mere trade
Grew to Empire; and he sent his armies forth
 South and north;
Till the country, from Peshawar to Ceylon,
 Was his own."*

* "The lands were the property of the Crown and were annually let to zamindars."—Verelst, "View," p. 65.

* "A Tale of Two Cities," in *Departmental Ditties*. The late Dr. Wilson has well said: "If the common opinion about these matters were true, if old Fort William was the work of thoughtless, worthless adventurers, and the Indian Empire the outcome of chance and accident, I, for my part, do not see how such views can be reconciled with scientific theories of history, much less with a belief in an over-ruling Providence rewarding men according to their works. But the truth is far otherwise. There can be no greater mistake than to suppose that the English settlement at Calcutta was

Hosted by Google

Mere trade was never good trade, and *mere* trade never led to empire. The growth of a rural administration is the secret of the expansion of English influence in Bengal; and it is of this growth, despite blunders, despite personal wrong-doing in all directions, despite unintelligent criticism of self-seeking advocates at home, these old records—sometimes like the writing of Mr. Sims, of Calcutta :—

"And a very pleasant running hand good Mr. Sims did write,
His up-strokes were like gossamer, his down-strokes black as night,
And his lines all clear and sparkling, like a rivulet in May,
Meandered o'er the folios—alas, and well-a-day!"

and sometimes "chips of paper mingled with the granular dust that white ants leave behind,"—tell the tale.

The old District Records of Midnapur and Chittagong, then, take us back to the earliest attempts of the Company's servants to establish an internal administration in Bengal. For Chittagong we have, of course, an excellent account of the records in Sir H. J. S. Cotton's "Memorandum on the Revenue History of Chittagong," published thirty-one years ago, and now exceedingly difficult to procure. I am glad to be able to report that, before leaving India, I supervised the work of haivng the Chittagong records copied, and their printed publication will, I believe, follow on my return from furlough. The Midnapur records, as I have already stated, were copied almost entirely by myself, as the work of deciphering them frequently required an experienced eye. I will say something later on about the work achieved in connection with the districts of Sylhet, Dinajpur, and Rangpur, which belong to the Diwani portion of Bengal, and relate to an early history of a different character from that of the Ceded lands.

When in 1765 Lord Clive secured the Diwani for Bengal, the Council at Calcutta determined that they would not enter at once into the direct administration of their newly-acquired revenues. Verelst, in the work I have referred to, tells us that the Council "very wisely determined to assume the slow but certain conviction of experience for their guide, giving their first attention to these provinces, the revenues of which had been subject to the administration of Europeans from the first cession of these lands by Mir Kasim in 1760. The event corresponded to their views. In the year 1769 the condition of these last-mentioned provinces formed so striking a contrast to the other parts of Bengal, where the oppression of ancient government was universally felt, that foreigners as well as natives began earnestly to wish for a more extensive reformation." * The Ceded and Calcutta lands were thus the hard school in which the Company's servants gained a valuable experience in the work of internal administration ; and in 1769, when Verelst was himself Governor, the authorities at Calcutta, "taking advantage of an equivocal permission in a letter from the Court of Directors, sent forth English Supervisors to take stock of, and, by strong moral pressure, improve the course of justice, criminal as well as civil, render the collection of the land revenue as little oppressive to the ryots, and to inquire into and report upon the history of their respective districts since the time of Suzah Cawn, as, at that era of good order and good government, no alterations had taken place in the ancient divisions of the country, and the confusion which is now apparent has been posterior to those times."† These Supervisors, as we know, ultimately became Collectors. For no good reason this institution of Verelst's has been derided. Had the reports of the Supervisors been before the eyes of our historians, I cannot help thinking that they would not have so rashly followed Kaye in scoffing at a measure which was exceedingly fruitful in new stores of information, and which effected some marked improvements in the conditions of the people. For what was done by these early European agents of the Company in the lands of the Diwani portion, we need to have to hand the records of the Resident at the Durbar.‡ I have only been able to see portions of these records, but what I have seen enables me to speak with confidence as to their great historical value.

fortuitous and ill-considered. Nothing can be further from the facts than the generally accepted picture of 'the mid-day halt of Charnock,' growing to be a city, 'chance-directed, chance-erected,' spreading chaotic like the fungus. Had the English confined themselves to 'mere trade,' had the merchant remained 'meek and tame, where his timid foot first halted,' there would have been no Calcutta and no British India."—"Bengal : Past and Present," Vol. I. p. 30.

* Verelst, "View," p. 75.

† *Ibid.*, p. 230.

‡ The Comptrolling Council of Murshidabad, constituted by the letter of July 13th, 1770, from the President and Council of Fort William, created a new jurisdiction to take the place of the Resident at the Durbar. Becher, who had been filling the office of Resident, became chief of the Comptrolling Council. The records of the Resident at the Durbar are, according to Mr. A. P. Muddiman, to be found at the Bengal Secretariat, but a "tattered and mutilated' letter copy-book of the Supervisors of Nattor, commencing December 30th, 1769, is preserved at the Nizamat record room at Berhampur. The Comptrolling Council of Murshidabad sat for the last time in September, 1772, and its records are now at the Bengal Secretariat in Calcutta. After its

Hosted by Google

Luke Scrafton, and, immediately following him, Warren Hastings, had held the office of Resident at the Durbar, but apparently the office as originally formed came to an end when Hastings was brought down in 1761 to take his place as a member at the Council Board of Fort William. In 1765, after the grant of the Diwani, Mr. Francis Sykes (afterwards a baronet) was sent to Murshidabad to take up the post of Resident on a new and magnificent scale. In addition to his fixed salary as a Company's servant, I find that in less than two years he received £35,757 18*s.* as his share of the commission allowed on the revenues—about £6,200 from the Malkaut or additional cesses, and close on £2,000 in complementary donations at the time of the Punya. In addition to this he had a sumptuary allowance amounting to about £4,450 a year. It need hardly be said that Mr. Sykes had a private business of his own. The Resident from the very first supervised the work of the Naib Diwan, who Macaulay seems to think was absolutely uncontrolled; and on at least one day in each week the Resident inspected the courts at Murshidabad—a place which I may, perhaps, remind you was, until the time of Lord Cornwallis, spoken of as "the City," in distinction to Calcutta, which was called "the Presidency."

Sykes was succeeded in 1769 by Richard Becher—a person with an exceedingly pathetic history, of which Dr. Busteed has written in "Echoes from Old Calcutta," and Sir William Hunter in his "Thackerays in India." It was with Becher, as Resident, that the Supervisors corresponded. Becher's personality is strikingly exhibited in the history of the great famine of 1770. Hunter speaks of him as the one Englishman who really made a resolute attempt to meet the exigencies of that terrible situation. I fancy that Hunter, in casting blame on Cartier's government at Calcutta, did not realise that Becher was practically the responsible person, and I do not think that Hunter had before him sufficient evidence on which to form an opinion. Until we have achieved more in the direction of the printing of the District Records I feel certain our judgment cannot be adequately confirmed, and it is no small evil that the withholding of historical materials renders it possible for any disloyal and irresponsible scribbler to compile "economic histories" which are economic only in the sense that they emit the truth in scanty rays. A curious instance, on the other hand, of the way in which officials have been compelled to rely on the happy-go-lucky researches of chance record-hunters, is afforded by James Grant's "Analysis of the Finances of Bengal," which was compiled from public records which had fallen into private hands, and purchased by Grant for his personal edification.*

It need hardly be said that these records throw a full light on the condition of the Province at the time our first administrators entered it. The further research goes back in the past the more remote seems to be that golden age which modern unrestful persons depict in their speeches to men in the street. The utter anarchy, the completeness of the breakdown of Moghul order (if such a thing ever existed), the vast hordes of armed Hindu mendicants, the organisation of open murders and pillage by ancestral dakoits, the rack-renting of the cultivators, the connivance of the landowners (with whom lay the police), are not to be met with occasionally, but form a constant feature in the picture.

I have attempted to challenge the prevalent view taken by historians—notably by Macaulay—that until the Court of Directors in 1771 sent out their famous decision "to stand forth as Diwan," the servants of the Company had done nothing in the way of rural government. It has been shown that in the important districts of Burdwan, Midnapur, and Chittagong, and also in the Twenty-four Parganas, the Company managed its revenues from the first, and that even in the Diwani portion the transactions of the native official at Burdwan were supervised by the English Resident at the Durbar. In regard to the administration of civil justice in Calcutta and in the Twenty-four Parganas the Company was itself the zamindar, and held the customary zamindary courts. In the Ceded lands the Company attempted "to maintain the forms of the ancient country judicatures, and at the same time correct many abuses." In the Diwani portion the Supervisors in 1769 were directed "to make strict and speedy inquiry into the proceedings of the courts of justice throughout their settlements, and that if any extraordinary powers have interfered to interrupt the

dissolution, the Resident of the Durbar (Samuel Middleton) occupied his old position in revenue affairs, and his records are in the Nizamat record room of the Murshidabad Collectorate. In February, 1775, Edward Baber, the then Resident, became chief of the Provincial Council of Murshidabad, and the office of Resident became purely political. The records of the Provincial Councils (instituted November, 1773) are widely scattered. Those of the Calcutta Provincial Council, which, after May 12th, 1780, assembled at Hughli, would illustrate the partisan divisions of subordinate bodies created by the great opposition of Francis at the Council itself.

* About two years ago I noticed some fragments of the old Factory Records of India quoted for sale in a secondhand bookseller's catalogue; the price asked was high, as an autograph letter from Lord Clive was included.

Hosted by Google

course and administration of justice, they should, without delay, correct all such abuses." When the Court of Directors were first informed of the acceptance of the Diwani by their Governor in Bengal, they wrote out: "The administration of justice, the appointment of officers, zamindaries—in short, whatever comes under the head of civil administration, we understand remain in the hands of the Nabob and his ministers." This was an error, for the civil courts, both at the capital and in the district (Sudder and Mofussil Diwani Adalat) were constitutionally part of the Diwani. In March, 1768, the Court of Directors went so far in the other direction as to recommend the Select Committee to endeavour to introduce a law of inheritance, "as near as possible to the laws of this country," to abolish the power of seizing the effects of persons dying without children, and to introduce the right of bequeathing by will. It would seem that Sykes was successful in getting some very necessary new judicatures established at Murshidabad, and we find the Supervisor of Nattor, March 4th, 1771, abolishing a petty criminal court, which he calls the Bazy-Jumma, while the Supervisor of Dinajpur divides his district into divisions, creates courts, and selects the judges. In April, 1771, the Court of Directors sent out recommendations of various reforms in the courts, and at the end of the year the Council at Fort William wrote to head officers or councils of the various districts to give effect to these recommendations. From Midnapur, as we should have expected, the Resident writes in reply that the recommendations so far as his district was concerned were needless: "All the judicature in that district was exercised under the authority of the Resident and persons appointed by him in every Pargana; that all cases in inferior districts were reported to the Resident, and every case duly registered in the Phousdar's cutcherry, so that there were no arbitrary fines or impositions, or any undue authority exercised, independent of the Resident."

With regard to the administration of criminal justice, there is much truth in Lord Macaulay's observation. For this administration belonged to the Nizamat, and not to the Diwani with which the Company had been invested. The apprehension of criminals was, indeed, an ordinary duty of the zamindar, but their trial belonged to the Faujdar appointed by the Nawab. For the punishment of crimes of a serious nature it would seem that the sentences were sent down from the Nizamat authorities at Murshidabad. The Chittagong records, in particular, throw a lurid light on the nature of these sentences. Here, for instance, is a list of penalties ordered by the Nizamat. The list is dated November 18th, 1773, and provides for eight dakoits to be confined in chains for three years; five dakoits who had committed murder to suffer death; nine housebreakers each to receive fifty strokes of the korah; a case of manslaughter to be punished by fine, and two men to have "their right hand and left foot cut off." The Chief of Chittagong, on his own authority, suspended the execution of the sentence of mutilation, but on July 11th, 1774, the Governor (Warren Hastings) writes: "The officers of the Nizamat Adalat have again declared the propriety of the sentence, and that it is strictly conformable to Mohammedan law. As the natives are not to be tried by our notions of justice, but by the established law of the country (excepting in very extraordinary cases, where it has been usual for Government to interfere), I must request that you will permit the officers appointed for the purpose to carry the warrants into immediate execution." The same records, on three or four occasions, give instances of the terrible infliction of death by impalement. The Collector of Behar, as late as December 24th, 1789, writes in an official report: "I hope that humanity will not be shocked by staked spectacles writhing in agony, if superior judgment shall resolve that partial torture does not promote general security."

The District Records supply some exceedingly strange instances of Mohammedan criminal law. Murder, being viewed rather as an offence against a particular family than against society, could be pardoned by the murdered man's heir; and as the heir would be in terror of incurring the anger of the criminal's kindred or of infuriating the judge by rejecting his intercessions, he would, to borrow the language of the records, "be glad to relinquish a painful privilege which involves timid minds in a delicate embarrassment." The choice of the weapon used to kill would decide whether or no the killing constituted an act of wilful murder or not; to kill with a sword or a knife would admit of the worst construction, but to hold the head of a child under water until death ensued would not of necessity be intentional murder. An accepted comment on the Koran, to the Collector's indignation, led to the mitigation of the sentence of death pronounced on a man who had in a very brutal manner murdered his child. The

Hosted by Google

commentator had ruled that the death of an adult was more than equivalent for the destruction of a child.

From what has been said it will be seen that the value of these old Bengal District Records lies in this, that they are the most important evidence we have in order to enable us to construct the history of the really effective occupation of the country by English administrators or supervisors. Our ordinary history books tell us much of the battles and the treaties by which the Company secured its military supremacy, or its legal titles, but the essential duty of the historian is not so much to record the acquisition of titles by force of arms or treaty, as to trace the actual advent of English influences over the lives of the inhabitants of the country. Various authorities have discussed the question when was territorial sovereignty in India acquired, but this, like the famous question "is the State the landowner in India ?" is a matter which entirely depends on the meaning we assign to certain abstractions. When the student begins to study Indian history at all seriously, the first thing he must do is to unlearn what he has been taught in his school books: "1757. Calcutta retaken. The battle of Plassey (June 23rd) secures Bengal for England." * It is disappointing, to say the least of it, to find that the "Cambridge Modern History" (Vol. VIII.), simply scamps the task of telling us how the English entered into touch with the millions whose increasing happiness is the sole justification for all that England has spent in India by the lifelong exile or early death of her sons, the sufferings of hundreds of English women and children, and the loss of things for which an income in excess of that which may be ordinarily earned by industry at home, or an assured pension, are in no sense equivalents. To these old records we must turn if we wish to recover the story of the real influence of English government on the people, the authentic motives and actual results of English administration.

In 1782 Philip Francis, after his return from India, declared, "Under a European Government Bengal cannot flourish," and pleaded that, "Europeans in Bengal should be limited to as small a number as the services of the Government will admit of."† The existence of the great European merchant houses of Calcutta and Bombay affords a sufficient comment on Sir Philip's words about the European in India not in Government service: "Exclusive of public employment, or contracts with the India Company, there is no occupation for the industry of Europeans in Bengal. Every enterprise they engage in, whether of foreign commerce or internal improvement, leads them into distress, if it does not end in their ruin." Exceedingly interesting results would be obtained if the records of the various factories could be recovered and placed under contribution. I understand that some at least of the proceedings of the now long defunct Board of Trade are to be found in the record room of the Board of Revenue at Calcutta. The rural records, which I have been dealing with exclusively, do, as a matter of fact, throw some light on the commencement of private European industrial undertakings—the growth of the indigo plantations, for instance.

There is one very important point to be remembered in connection with these records—and indeed all records which are to be used as materials for history. The writers often, if not always, write in order to put on record what is likely to be unknown or easily forgotten, and a knowledge of all that was widely known and easily remembered is taken for granted. Thus a great event, because it created a stir, and was a matter of knowledge to superiors at headquarters, may be only just alluded to, or a few of its circumstances or consequences detailed, in the daily correspondence, while a hundred and one matters of very minor importance are treated with tedious amplitude. It is quite characteristic, for instance, that the Court Chronicler of the Manipur Raj, tells us very little about the taking of Manipur by the English ; while he does record the days on which the guilty persons were hung. The capture of the place, just because it was the supreme event, escapes with but small notice. So it is with the great famine of 1770 in the English rural records. The references to it are surprisingly scanty, and on the principles of a certain kind of criticism with which we have been troubled far too much, it would be necessary to adopt a tone of enlightened scepticism about the famine ! As a matter of fact, it is the very silence of the records, in these and like cases, which is so eloquent.

If I had time to deal with the element of personal interest, I should take my illustration from the career of the Hon. Robert Lindsay, as disclosed by the Sylhet records. I should tell you the story of how that remarkable man, while

* Acland and Ransome, "English Political History," p. 138.

† Francis, "Original Minutes." Introduction. The word "Government" in the usage of Anglo-Indians of this time usually denoted, not the Company, but the Nizamat. Barwell usually speaks of the Company in its governmental capacity as "the Publick."

Hosted by Google

ruling one of the most turbulent frontier districts with conspicuous ability and success, controlled by personal influence the wild tribes on the Khasi border, and built up for himself a noble fortune by the industries of which even shipbuilding, at his far-inland station, was one. I should tell you how, to meet a famine, Lindsay exported rice to Madras in ships of his own building, and how, by a happy bid with the Government at Calcutta, he obtained control of the cowries in which the revenue was transmitted, and so secured almost a monopoly of the famous Sylhet lime. And if it had been my good fortune to have studied the records preserved at the remote little station of Dumka, I should, had the time been mine, been unable to resist the temptation of describing to you the ever-memorable work of Cleveland amidst his half-savage hillsmen. I should have been tempted to travel beyond the limit of my own special period, and from the records at stations on the Brahmaputra tell you of one who, if he had in the Punjab performed the things he did on the too-little regarded North-East Frontier, would have engraved his name in the temple of fame side by side with the Lawrences. I refer to David Scott, whose memory has not lost its magic in Assam, and whose lofty monument looks down from the rain-beaten crags of Cherra Punji, over the dreamy plains of the valley of the Surma.

An apology is no doubt due for the occasional references I have had to make to my own work, and I have more than hinted that a date is set as a limit to my researches. That date is the date of the permanent settlement of Bengal and Lord Cornwallis's reforms. To have travelled down nearer to our own time would have necessitated a stern refusal to take a wide survey. Several valuable treatises have been compiled on the records of various stations whose names I have mentioned. We have, for instance, Cotton on Chittagong, Field on Midnapur, Glazier on Rangpur, Beveridge on Bakarganj, Westland on Jessore, Hand on Behar; but, with all humility, I venture to say that the value of these books has to some extent been impaired by their several authors having restricted their attention too strictly to the records preserved in their own particular record rooms.* It is for this reason I have preferred to limit my period, and to utilise the time saved for the study of more than one series of local records at one time. While reading the official records, I have derived much assistance from the perusal of the private letter-copybooks of Richard Barwell, which are now the property of the almost defunct Calcutta Historical Society.

In speaking of works already in print, Sir W. Hunter's four volumes of "Bengal MSS." should not be forgotten.* Useful as these volumes are, they do not give us the letters *in extenso*, but in provokingly brief *précis*. Sir W. Hunter makes selections only from the records preserved at the offices of the Bengal Board of Revenue in Calcutta. In the "Rural Annals" the records of only a few districts came under survey, and Sir William can only be said to have made a very partial use of these. Mr. E. G. Drake Brockman, in a far too scantily printed pamphlet, has shown that the first harvest of the "Rural Annals" in these comparatively obscure districts, has left the greater part of the fields unreaped.

The reading of this paper affords a natural occasion of expressing my gratitude to those who have indulged me with the opportunity of making what have been to me the most delightful leisure-time studies. By the courtesy of the Government of India I have been enabled to collect together a series of documents relative to the French Settlement of Chandarnagore during the time of the war between France and England. These documents have nearly all appeared, in a rather unclassified array, in various numbers of "Bengal: Past and Present," and thanks to my co-adjutors the origin of this isolated dependency of France has now been set in a clear light. For many suggestions, and the loan of a valuable report, I am indebted to Mr. A. P. Muddiman, I.C.S. To the Government of Bengal I am indebted for a lengthy loan of all the early Midnapur records. Mr. R. J. Hirst also worked out for "Bengal: Past and Present" (Vol. VI.) a description of the Burdwan records from 1786 to 1790. To Mr. J. Rankin, I.C.S., I am indebted for the sight of copies of old

* An illustration is afforded by Mr. Westland's assertion that not till 1781 did the English attempt anything of the nature of real internal administration. The records of Jessore, as actually found at that place, might bear this out, and it is on these locally-preserved records that Mr. Westland's book is based. Westland, therefore, commences his survey of the English activities in Jessore with the correspondence of Mr. Henckell, appointed judge and magistrate in 1781; and Mr. Westland clearly had no knowledge of the correspondence of Robert Wilmot, Supervisor of Jessore in 1769, and the evidence relating to the history of the district to be found in the correspondence of the Resident at the Durbar and in the proceedings of the Murshidabad Comptrolling Council of Revenue.

* Long's "Selections from the Unpublished Records" do not require notice here, as we have district records only under consideration; but Mr. Long's volume amply illustrates the unwisdom of publishing records in selections only.

Hosted by Google

Dacca papers. To the Government of Eastern Bengal and Assam I am most deeply indebted, not only for defraying the expense of journeys to Sylhet and Rangpur, and for the loan of records from both those places and Dinajpur into the bargain, but for their kind consent to have these records printed at the Secretariat Press. The kindness of Sir Lancelot Hare, the recently retired Lieutenant-Governor of Eastern Bengal and Assam, and that of three chief secretaries in succession—Mr. Lyon, Mr. Nathan and Mr. Beatson Bell—has been the greatest encouragement to me to go on with the work with a zeal unimpaired by the difficulties inseparable from an undertaking so intricate and so lengthy.

APPENDIX I.

EXPLANATION OF SOME TERMS EMPLOYED IN MR. FIRMINGER'S PAPER.

Diwani and Nizamat. The prince (Nawab) who occupied the *musnud* (throne) at Murshidabad, was Viceroy of the Emperor of Delhi, and was usually described as the Subahdar of Bengal, Behar, and Orissa, although the greater part of the last-named place had been seized by the Mahrattas and was ruled by them from Cuttack. As commander of the imperial forces, the Nawab lost all military power by the Emperor's *farman* (grant or charter) of August 12th, 1765, which placed the military defence of the Province in the hands of the Company, and by the treaty with the Nawab Nadjam-ud-Daulah, February 25th, 1765, which limited the troops maintained by the Nawab to the support of his personal dignity. As *Nazim* the Nawab was the chief officer charged with the administration of the criminal law (*i.e.*, that of the *Koran*) and the olice; as *Diwan* he was charged with the administration of the civil law and the collection of the revenues. The idea of separating these two offices, and conferring the second on the Company seems to have originated with the Emperor Shah Alam, and was the subject of a proposal made by him to either Eyre Coote or Carnac in 1761. The grant of the *Diwani* (office of the Diwan), August 12th, 1765, coupled with the right to exercise military power, left the Nizamat alone to the Nawab, but the English at the time, and long after, held that the executive power was centred in the *Nazim* or holder of the Nizamat. On his retirement from office, Governor Verelst, December 16th, 1769, warned his successor, John Cartier: "We have reached that supreme line, which to pass would be an open avowal of sovereignty. It should be remembered that we cannot be more, without being greater than sound policy allows; the interests of our employers at home, no less than our national connections abroad, forbid it . . . Every order should scrupulously wear the sanction of the native Government."—Verelst, "View," p. 123. It was this constant dread of awakening the jealousy of European Powers which dictated the delay of the Company in realising what the grant of the collection of the revenues, the exercise of military power, and the supervision of civil justice involved. Verelst himself seems to have seen that the protection of the people who paid the revenues was bound to lead to the ending of a state of divided power, in which the native hardly knew to whom he was to yield obedience. In the same letter he writes: "Paradoxes are not to be reconciled, highly injurious to our national character, dangerous to the best defended establishment, and absolutely bordering on inhumanity." In 1775, Francis, Clavering, and Monson attempted to stay the trial of the Fowkes, Nuncomar, and Rada Chun, by claiming for the last-named an exemption from jurisdiction on the ground that, as Vakil to the Nawab, he held the privileged position of an ambassador from a sovereign power. The judges did not feel themselves bound to pronounce on the subject of the sovereign power claimed for the Nawab, but dismissed the objection on other grounds. In 1772 the Supreme Criminal Court (Nizamat Adalat) was brought down to Calcutta, and placed under the charge of a Darogha (Superintendent), subject to the control of the President of the Council, who revised the sentences of the criminal courts in capital cases. In October, 1775, the Nizamat Adalat was sent back to "the City" (Murshidabad) and placed under the Naib Nazim (deputy to the Nazim). Some material changes were effected in 1781, but in 1790 Lord Cornwallis's regulations effaced the last vestiges of the authority of the Nawab as Nazim.

Faujdar (fauj = an army, dar = one who holds or owns; corruptly, "phousdar"). Originally a military official, but in the early English period the chief Mohammedan executive officer of a district in all matters connected with the peace of the district.

Zamindar (zamin = land). Whether the zamindar really owned the land or was merely the State-appointed collector of the revenue from a given area or areas, is a much discussed question. The terms of the sanads (or patents) conferring the position required the zamindar not only to collect duly and render in the land revenue, but also to maintain the roads in good order, to apprehend thiefs and robbers, and send them for trial, to protect travellers, and to suppress drunkenness. The land revenue represents the ancient right of Government to a share in the harvest reaped by the cultivators. It is frequently, but misleadingly, spoken of as "rent," and also as a "land tax."

APPENDIX II.

DATES OF PRINCIPAL ALTERATIONS IN REVENUE ADMINISTRATION.

1633. Factories at Balasore and Hariharapur founded by Cartwright, seemingly on the authority of a charter (*farman*) from the Emperor Shah Jehan.

1650. Possible activities of Surgeon Gabriel Boughton in obtaining trade privileges for the English.

1651. Bridgeman and Stephens found a factory at Hughli. In the years following factories established at Patna, Cossimbazar, Dacca, Malda, etc.

1686. December 20th. Job Charnock abandons Hughli.

1690. August 24th. Charnock's "Mid-day halt." The birthday of modern Calcutta.

1698. Azim-us-Shan, grandson of Aurangzeb, gives permission for the purchase from the native zamindar of the talukdari rights of Calcutta, Sutanuti, and Gobindpur, subject to an annual payment of 1,195 rupees.

1699. Ralph Sheldon becomes the first Collector of Calcutta.

1714–17. The Surman Embassy to the Court of the Emperor Farokhsir, who grants the English permission to purchase the talukdari right of thirty-eight villages adjacent to Calcutta. The Nawab, Murshed Kuli Khan, prevents the purchase.

1756. June 21st. The tragedy of the "Black Hole."

1757. January 2nd. Clive and Watson recapture Calcutta. (Justice Hyde, Justice Chambers consenting, in the case of Bakshi Ali: "We say the inhabitants of this town are all British subjects, because this town was conquered by Admiral Watson and Colonel Clive, but that does not extend to subordinate factories."—Morton, *Decisions*, p. 103.)

1757. February 9th. Treaty with Suraj-ud-Daulah. The zamindars permitted to sell according to Farokhsir's *farman*.

1757. June 23rd. Plassey. Mir Jafar agrees to grant to the Company the land within the Mahratta Ditch and 600 yards without, and the lands south of Calcutta as far as Kalpi, on payment of a quit-rent. Origin of the Twenty-four Parganas.

1759. Mahomed Ali Gohur (afterwards Emperor Shah Alam) invades Behar. Mir Jafar, alarmed by the idea of Clive supporting the Prince, grants Clive, as a token of gratitude, as *jagir* or assignment, the rent of the Twenty-four Parganas. By an imperial *farman*, June 23rd, 1765, this jagir was confirmed to Clive for ten years, from May 10th, 1764, after the lapse of which term or Clive's death, the jagir was to revert to the Company as an unconditional gift.

1760. September 27th. Treaty with Mir Cosim (Mir Kasim). The revenue of Burdwan, Midnapur, and Chittagong assigned to the Company to defray the charges of their army. (The Burdwan revenues had been temporarily assigned for that purpose at an earlier date.)

1763. July. Mir Jafar, on his restitution, confirms the cession of Burdwan, etc., etc.

1765. January. Mir Jafar dies.

1765. February 25th. Treaty with Nadjam-ud-Daulah, who confirms all previous grants, and undertakes to maintain troops solely sufficient in number for the preservation of his personal dignity.

1765. August 12th. The Emperor grants the Diwani to the Company.

1769. Appointment of English Supervisors throughout the Diwani portion.

1770. The Court of Directors, letter dated March 23rd, 1770, order a Controlling Committee of Revenue to be formed consisting of four members, to whom the entire management of the revenues is to be entrusted.

1770. July. The President and Council constitute Controlling Councils of Revenue at Murshidabad and Patna.

1771. The Comptrolling Committee, as ordered by the Court of Directors, formed, and sits for the first time on April 1st.

1771. August 28th. The Court of Directors write the letter in which they express the determination to stand forth as Diwan, and "take upon themselves entire care and management of the revenues by the agency of the Company's servants."

1772. April 13th. Hastings assumes the post of Governor.

The Committee of Circuit makes a five years' settlement by farming the collections to the highest bidder. The Khalsa ("Exchequer") brought from Murshidabad to Calcutta. The Supervisors renamed Collectors.

Regulations for the administration of justice.

1773. November 23rd. Upon the arrival of orders from the Court of Directors, the system of 1772 has to be revised, and a plan, part intended to be permanent, and a part temporary only, is adopted.

a. Permanent.

1. Native diwans or aumils to be appointed to each district, except such as have been let to zamindars or responsible farmers.

2. A Committee of Revenue formed at the Presidency, consisting of two members of the Board, and three senior servants below Council.*

* Mr. Muddiman writes: "Of the five Provincial Councils constituted by this change, the Calcutta Committee of Revenue is the one which has caused so much confusion in the Secretariat and Board's record rooms. It will be observed that this body was in no way the supreme record authority, which remained, as before, the Revenue Board consisting of the whole Council, but merely a co-ordinate authority with the other five established. It has been, as a rule, confused with the Committee of Revenue, which replaced the Provincial Councils for the whole country in 1781."

Hosted by Google

3. Commissioners to be appointed for purpose of inquiry as occasion occurs.

β. Temporary. Bengal and Behar divided into six Provincial Councils (Murshidabad, Burdwan, Dinajpur, Dacca, Calcutta, and Patna)* each composed of a chief and four senior servants.

The Collectors to be withdrawn on finishing their current treasury, and Naibs to be appointed to hold courts of Diwani Adalat in subordinate districts, and members of the Council to hold the civil courts at their respective head stations.

1775. Great revenue debates and rival plans put forward by Hastings and Barwell conjointly on the one hand, and Philip Francis on the other. Francis opposes the Governor's proposal to institute an inquiry into the revenues, which, however, is carried. Francis advocates a permanent settlement with the zamindars.

1776. The Commission of Anderson, Croftes, and Bogle to inquire and report on the revenues.

1780. Six provincial civil judges, independent of the Revenue authorities, appointed.

1781. February. Committee of Revenue formed (by five senior servants) at the Presidency. Provincial Councils abolished. Office of Superintendent of the Khalsa Records abolished, and that of Preparer of Reports to the Board of Revenue instituted. European collectors return to the districts.

[A corrupt motive for the abolition of the Provincial Councils was imputed to Warren Hastings at his impeachment, but the records show that the Provincial Councils from the very first had been regarded as a temporary measure only.]

1786. June 1st. The Board of Revenue instituted—a junior member of the Council and five senior servants of the Company—subject to the general control of the Governor-General in Council.

In the absence of the author the paper was read by the Rev. J. A. V. Magee, M.A.

DISCUSSION.

The Chairman thought it would be agreed that the paper had been a most instructive and interesting one, for which a debt of gratitude was owing to the author. Also the Society was much obliged to Mr. Magee for coming forward to read it. One point that immediately struck him after listening to the paper was the vast amount of material that lay buried in the District Records of Bengal. In the two Bengals there were more than forty-five districts, and one could form some idea as to the amount and variety of the materials that lay hidden there. The paper gave ample testimony to the value of these materials from the historical point of view. To utilise these fully, it appeared to him that the first thing to do was to take up each district separately and to gather together all the papers that might be found of interest and importance, and then to collate them collectively in order to obtain a proper and full account of that period of the history of Bengal to which they relate. The records after all did not cover a very long time; they began some years after the Battle of Plassey, and went on to the time when Lord Cornwallis introduced the permanent settlement, and thereby practically reduced the interest in the land administration of Bengal. But the records of those years were of the greatest interest and value, owing to the fact that they covered the experiments and the trials that were made at the time to introduce order and good government out of the chaos in which the country was when the Mohammedan power broke up and the English came upon the scene. They showed how civil government was gradually evolved out of absolute disorder and confusion. In that respect the records for that short period of twenty-five years were of the greatest value, and he thought they were of greater importance than any records that could be found elsewhere in India in connection with the early period of British history. He hoped that the records would not be left to be dealt with by individual enthusiasts, as had been hitherto the case, but that the work would be taken up systematically and thoroughly. If that were done, he had no doubt the historian of the future would find the material of the greatest value.

Mr. S. Charles Hill (Director of Public Instruction, C.P.) said there was one point in Mr. Firminger's very interesting paper which was of extreme importance, and which had been already referred to by the Chairman, namely, the necessity of printing the early records of Bengal in full. The author, of course, had spoken only of the records of Bengal, but he himself had had to deal with the records of the Government of India at Calcutta, and recently he had seen something of the Presidency records of Madras, and what held good of Bengal held good, he thought, of the other Presidencies. He himself had been one of the enthusiasts referred to by Sir Krishna, and had published for the Government of India a collection of papers dealing with a certain period in Bengal. He found that that involved a very unpleasant responsibility. If he excluded any paper it appeared as though he said that the paper was of no use whatever, while all the time he knew that no one could say that of any paper. No paper could be said to be useless until all the papers had been printed and studied by various students from different points of view. A paper which was useless at one time might become very useful later on, and he thought the mere enumeration of the various papers the author had given showed that a very large quantity of information was lying hidden in the District offices and in the Presidency offices of

* Behar remained under the Chief Council of Patna until the abolition of the Provincial Councils in 1781. The Chief of Chittagong (and Tippera), under the system of 1773, corresponded direct with the Board.

Hosted by Google

India, information which was absolutely necessary to form a correct estimate of what the English had done in Bengal. It was, however, not only the past people were interested in; they were also interested in the future. Therefore, he thought the value of the records should be considered, not merely from mere sentiment for the past, but with regard to their guiding effect in the future. When the East India Company conquered India, it took over the administration of the country as the easiest way of obtaining that order and peace which were needed by the Company for its own trade, and by the people of India to recover from the chaotic condition into which they had fallen by the break-up of the Mogul Empire. It was easier for the Company to govern by Europeans than by the natives. In various cases they tried to govern through Indian officials, but, owing to one misapprehension or another, or change of policy, most of those attempts ended disastrously. So much was that the case that an idea grew up that the natives of the country could never manage things for themselves. That was an exploded idea now. Great Britain was no longer simply trying to develop the country, but desired that the people of the country should have a chance of developing things themselves. Statesmen were not concerned simply to find out what India wanted; they wished to know whether the people of India were capable of doing the work for themselves. If that was true, the first thing to be done was to know exactly what the people of India were, and what their capacities were, and also their desires and wishes; and he did not think information of that kind could be found anywhere so well as in the early records. The records were not simply statements of what the English had done in India; they were also a storehouse of the knowledge and experience of some of the best men who ever went to India, men who were keenly interested in the country, and who put on record what they had learnt by careful inquiry and experiment. Without wishing to draw any comparison, he thought that possibly those men knew India better than any men now living could know it, because they lived in an India upon which the Western mask had not yet fallen. It was for that reason he wished to see the papers published. Madras was the only Presidency that had seriously faced the task of publishing its records, but he did not think it had yet undertaken the District Records, and he believed there was no other Province in India which had systematically undertaken the complete publication of any set of records whether Presidency or District. Every effort ought to be made for systematic publication at once. A complete publication was much more feasible and much more practicable than the publication of a set of collections on different subjects. To have a set of collections of papers on different subjects would necessitate either gathering all the records in one central place, or capable men going from district to district making inquiries from extremely busy men, and the inquirer would have at the end to confess that he was not getting anything like the information he wanted. On the other hand, systematic publication of the whole of the records would give something which would last for all time, and would meet all requirements.

MR. WILLIAM FOSTER (Registrar and Superintendent of Records, India Office) endorsed the plea that in dealing with the Indian records free and liberal use should be made of the printing press, especially when the records, as seemed to be the case in some instances, were fast perishing. Printing was cheap enough in India, and plenty of assistance could be obtained in the way of transcription. The great difficulty was to secure accurate proof-reading, to see that the printed paper truly reflected the original. When the Government had at its disposal the services of an enthusiastic student like the author, they could not do better than they were evidently doing, namely, print a number of the District Records; but he hoped they would go further still and print more of the records at Calcutta. In the Bengal Secretariat, as well as in the office of the Board of Revenue, there were immense stacks of papers about which little or nothing was known, and certainly they must contain documents of the utmost importance. All those interested in the study of Anglo-Indian records must welcome the author's efforts in that direction. It was well known what an excellent record Mr. Firminger had in the Calcutta Historical Society, which he practically founded, and which collapsed, he believed, mainly because Mr. Firminger came home to Europe. As editor of its journal, he did very good work, and also in editing volumes of the Society published from time to time. It was gratifying to find he was now studying in detail the contents of the district record rooms.

MR. WILMOT CORFIELD said, as an old resident in Calcutta, and as an old friend of the author, he should be sorry to let the opportunity pass without expressing the pleasure with which he had listened to the paper. Only those who had watched Mr. Firminger's efforts in Calcutta could be aware of the earnestness with which he had set to work in the direction in which his genius and his enthusiasm had led him. There was no man with such a capacity for devouring the most extraordinary mildewed documents; he seemed to revel in them, and always managed somehow or other to get something worth having out of them. The author said, in one part of his paper, that only to look at some of the documents meant that they were bound to be damaged; but that was rather a good thing, because if they were bound to be damaged, they were only damaged to be bound, and the more of them that were put together and rebound, the better it would be for the future. With regard to the Calcutta Historical Society, it was not entirely defunct, and there were many who were still hoping that it would renew its life. There was a

Hosted by Google

possibility, he believed, of the Asiatic Society of Bengal taking it over and continuing it in a somewhat modified form.

MR. H. LUTTMAN-JOHNSON said he had spent a good many years of his lifetime in Bengal, and had always taken a great interest in the records. It was over forty-two years since the late Sir William Hunter called attention to the value of the District Records; the subject had been talked about, but it was only recently that something was attempted to be done in a systematic way to bring the documents to the light of day. As had been said, it was no use leaving the work to the spasmodic efforts of hard worked officers; it must be done in the systematic way in which Mr. Firminger had done it, and the records of various districts must be compared in order to learn what was going on at the time when the British first occupied the country. The value of the records was great for various reasons, and one, to which not so much attention had been paid by the speakers, was that they showed the state of the country when the British first took over the Diwani and made themselves supreme. There was a possibility of forgetting what the results of that very ancient Hindu civilisation actually were in any particular part of the country. Bengal was a little different from Upper India, but there was no doubt there had been a king of Bengal and a ruling power, so that it was nothing like a primitive country, but in many ways was highly civilised. For instance, the Brahmins came down from Canouj more than a thousand years ago to improve the Bengalee's knowledge of the elements of Hinduism. These records would show exactly the result that ancient Hindu civilisation had upon the country. It was a country that had been enjoying the benefits of civilisation for at least two to three thousand years, and the records could not be other than extremely interesting, as showing what the results of that long period were. For five years he was Collector at Sylhet, and there saw something of the records, which were of extreme value from the point of view of writing books of adventure, and books interesting to the general public. For instance, the Hon. Robert Lindsay wrote an account of his doings in Sylhet, and it read like a novel. There was no doubt that in every district it was possible to extract material which would form a book equal to any novel. Even from the literary point of view, the publication of the annals was of importance. For instance, in the year 1770 there was a riot in Sylhet. It was put down, and eventually some of the leaders of the rioters escaped to the top of one of the isolated hills, and were attacked and overwhelmed by the Collector. There was a very amusing account of the events given in a letter, which ended up: "The Honourable Board will ask me what has become of these misguided persons. I have to inform the Honourable Board that those misguided persons are no more." Those who had been instrumental in bringing the District Records to light during the last few years had done a very great work for the country of Bengal and for the benefit of the present administrators.

SIR STEUART COLVIN BAYLEY, G.C.S.I., C.I.E., in proposing a vote of thanks to the author and to Mr. Magee for reading the paper, said the name of Firminger was familiar to a previous generation in India. Many years ago, in Bengal, everyone who took any interest in his garden knew the name, because Firminger's "Gardening" was the handbook which guided all who desired to make beautiful gardens in India. The present Mr. Firminger perhaps had done even a greater service, because he did not know that any greater service could be done to the people who took an interest in the early British history of India than to put them in the way of learning the truths about that history, and the facts. Mr. Firminger was also doing something whereby our previous notions of the history of British India had to be corrected. It had been learnt that even such a historian as Macaulay could be hopelessly wrong. From the time when Sir James FitzJames Stephens wrote his little book about Nuncoomar and Impey, all the historians who had studied the early records had found something to improve, and almost invariably showed that the earliest English administrators of Bengal were not such ruffians as they were supposed to be. The question which naturally arose was as to how the records were to be secured in the future. It had been suggested that Government should deliberately take up the work, and certainly it should not be left to the casual enthusiasm of amateurs. He had often thought that nothing could be a better training for a young civilian, in his first year or two, than, after a brief training at a central office, to turn him into the record rooms; it would excite his interest in his work and the people of the district as nothing else can; but even then it was probable he would be taken away in the middle of his work to be sent somewhere else, and therefore a regular fixed staff would be necessary. With regard to the question raised by the author as to whether the flimsy printing paper of the present day would last as long as that of our ancestors, the answer definitely was No. A very interesting inquiry had been made by the Royal Society of Arts some few years ago, when a very strong committee was appointed to inquire into the subject, and the general conclusion they came to was that wood-pulp paper would not last fifty years, and most printing was done on wood-pulp paper. There were good writing papers of course, but these were made of rags, and rags were everywhere being supplanted by cheaper materials, such as esparto grass at best, and wood-pulp at worst, and most of the paper now used for printing would be dust in fifty years. The German Government was so much interested in the subject, that it was manufacturing a special paper for its own use. If a department of the

Hosted by Google

Bengal Government took up the question, that would be a point they would have to consider, because it was no use printing on paper which would be dust in the course of a few years.

Sir Steyning Edgerley, K.C.V.O., C.I.E., in seconding the vote of thanks, said he belonged to another part of India, which, they were told, had not made much progress in searching into District Records. Most of the papers which were read before the Society were valuable for the information they gave to people in London, but the present paper would be very stimulating, if published, in India as well. He should be glad to see that it obtained recognition of that character, because people might thereby be found in other parts of India who would do the work that the author had been doing so successfully in Bengal.

The vote of thanks was carried unanimously.

The Rev. J. A. V. Magee briefly returned thanks on behalf of the author and himself, and the meeting concluded.

Mr. G. W. Forrest, C.I.E., writes as follows:—"I have read with considerable interest and utility the Rev. Mr. Firminger's paper on 'The Old District Records of Bengal.' It is a matter of considerable regret that I cannot attend the meeting of the Society, and offer my humble testimony as to the historical worth of the paper. It has not been my good fortune to meet Mr. Firminger, but I have closely followed his work, and I know of its high value to one historical student. The history of British administration from the beginning to the grant of the Diwani is greatly needed, and it can only be written from the old District Records. Many years ago it was proposed by me, as Director of Records, Government of India, that these manuscripts should be removed to Calcutta and kept in a central record office. This is the only way of preserving them from destruction. When they have been placed in a suitable repository, they ought to be fully examined and summarised, and the work, I trust, placed in the hands of Mr. Firminger, who evidently knows what is wanted, in the interests of the study of the history of British administration in India. In Bengal were laid down the first principles of that administration, and to be ignorant of them or depart from them without due consideration is dangerous."

Mr. Wilmot Corfield writes:—"I would suggest the transfer of the executive council of the Calcutta Historical Society to London, and the subsequent carrying on of its work in this city. 'Bengal: Past and Present' could be published just as economically in London as in Calcutta, with an Indian sub-council in constant touch with the London council. The Society (which so far has had a most successful career) might thus be continued on its course without a break. Incidentally, it would serve to maintain in fellowship retired Anglo-Indians and Indians resident in England, interested in historical research in Bengal, while at the same time offering an opportunity for publication of the valuable results of the inquiries and discoveries of Mr. Firminger and other writers. There are more historians and students of Bengal's past at any one time in London than there ever were or ever will be at any one time in Calcutta, while the opportunities in London of acquiring information, pictures, portraits, and other desirable material for the Journal, enormously exceed those that Calcutta could ever offer. The suggestion seems well worth serious consideration."

EIGHTH ORDINARY MEETING.

Wednesday, January 31st, 1912; Sir William H. White, K.C.B., LL.D., Sc.D., F.R.S., Vice-President of the Society, in the chair.

The following candidates were proposed for election as members of the Society:—

Sacoom, Samuel, Axim, Gold Coast Colony, West Africa.

Wood, Sir Henry J., 4, Elsworthy-road, N.W.

The following candidates were balloted for and duly elected members of the Society:—

Aiyar, Palayam Rajam Sesha, B.A., 10, Kuppumuthu-street, Mount-road, Madras, India.

Baker, Asa George, Messrs. G. & C. Merriam Company, Springfield, Massachusetts, U.S.A.

Barbour, James Foster, Maysville, Kentucky, U.S.A.

Bowles, George Vernon, c/o Messrs. Read Brothers, Ltd., Kentish Town, N.W.

Butt-Gow, H. F. S., Laimakuri, Dibrugarh P.O., Upper Assam, India.

Crouch, Vernon Foster, J.P., c/o Chief Native Commissioner, Salisbury, South Rhodesia, South Africa.

Durrant, Hubert Arthur, Hunstanton, Norfolk.

Eberle, Professor Eugene G., Ph.G., A.M., Dallas, Texas, U.S.A.

Fuchs, Ernest, Box 334, Guadalajara, Mexico.

Gibbs, Eustace L., Tyntesfield, Flax Bourton, Somerset.

Harkness, William Young, Lago Vista, Negritos Payta, Peru, South America.

Hughes, Vivian Arthur Beesley, Ellerslie, Grassfield-avenue, The Cliff, Manchester.

Langton, John James Perez, 421, South Seventh-street, St. Louis, Missouri, U.S.A.

Leitner, Henry, The Leitner Electrical Company, 7, Prince's-street, Westminster, S.W.

Ripper, Charles, 7, Laurel Bank, Lancaster.

Scotland, Alexander Paterson, Keetmanshoop, German South-west Africa.

Hosted by Google

Sen, Diwan Mangal, Gujranwala, Punjab, India.

Spence, David, Ph.D., F.I.C., The Diamond Rubber Company, Akron, Ohio, U.S.A.

Windass, John, F.S.A.M., The Hall, Osbaldwick, York.

The paper read was—

RADIO-TELEGRAPHY.

By Professor G. W. Osborn Howe, M.Sc., M.I.E.E.

It is not my intention this evening to describe in detail any of the apparatus employed in the various so-called systems of radio-telegraphy, but rather to explain, in as simple a way as possible, the general principles underlying all these systems, and to indicate the directions along which improvements have been made during the last few years.

Before considering the question of radio-telegraphy itself, one should have a clear idea of what is meant by an electrical oscillation, for electrical oscillations constitute the alpha and the omega of radio-telegraphic communication.

We are all familiar with examples of mechanical oscillations such as occur with the pendulum, the vibrating reed, and the violin string. If we examine these well-known phenomena a little more closely, we find that in every case there is a continual transformation of energy. At one moment the oscillating mass is moving rapidly, and possesses, therefore, a store of kinetic energy depending on the mass and its velocity. The next moment the moving mass is brought to rest, its kinetic energy having been all expended in overcoming gravity, or in stretching or compressing a spring. The energy has not been lost, however; it is stored in the spring, or, in the case of the pendulum, stored as the potential energy of the bob which is now at its highest point. The next moment this static energy is once more retransformed into kinetic energy as the heavy mass is set into motion, and so the transformation goes on until, failing a continual supply, the energy is all dissipated in the unavoidable frictional losses, and the oscillation is damped out. The rate at which it is damped out is called the decrement of the oscillation.

We see that the two essentials to mechanical oscillation are—(*a*) kinetic energy associated with motion; and (*b*) static energy associated with displacement.

Now the electrical oscillation is in every respect analogous to the mechanical. It is the electricity which oscillates or moves backwards and forwards. At one moment the electricity is in motion, producing what we call an electric current, at the next moment the electricity is at rest, and for a moment there is no current, but merely a stationary charge. When the electricity is in motion, the current passing round a coil of wire produces through and around the coil a magnetic field, and this magnetic field represents, or is the manifestation of, a storage of energy in the ether. Just as the kinetic energy of the moving mass is proportional to its mass and to the square of its velocity, so the energy of the magnetic field is proportional to what is called the inductance of the coil and to the square of the electric current.

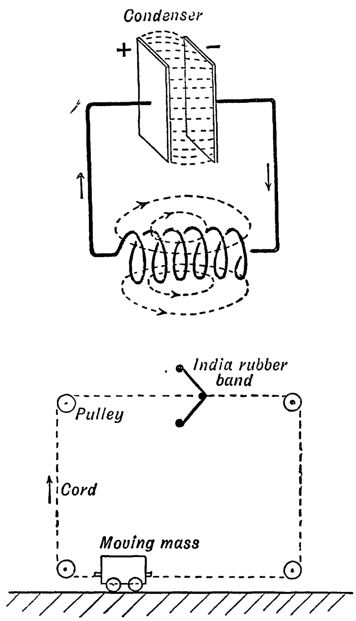

Fig. 1.

In circuit with the coil is some form of condenser, often one or more Leyden jars, consisting simply of two metal plates separated by air, glass, or oil, or some other insulating material. The result of the current is a transfer of electricity from one plate to the other until, when the current, and with it the magnetic field, finally falls to zero, all the energy which a moment ago was stored in the magnetic field is now stored in the space between the two plates as an electric or electro static field. There is at this moment a large pressure difference or potential difference between the two metal plates, and the potential difference causes a current to flow through the coil in the reverse direction, until, a moment later, the condenser is completely discharged, and all its energy is once again stored in the

magnetic field of the coil, only to be once again re-stored in the condenser in the reverse direction. Here, again, the oscillation will be gradually damped out, the frictional resistance of the mechanical analogies being replaced by the electrical resistance of the circuit.

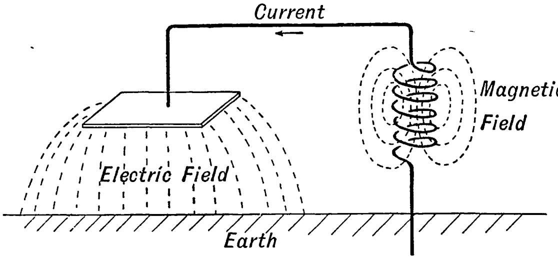

FIG. 2.

The frequency of the mechanical oscillations —*i.e.*, the number of oscillations per second— depends on two things, viz., the mass, m, of the moving part and the yield or displacement, y, of the spring to unit force. In the electrical oscillation, the frequency depends on the two analogous quantities, viz., the inductance, L, of the coil and the capacity, K, of the condenser, by which we mean the electrical displacement or quantity of electricity transferred from one plate to the other by the application of unit potential difference.*

If the plates of the condenser in Fig. 1 be pulled further apart we merely decrease its capacity and increase the frequency of the oscillation. No fundamental difference is made by using the earth as the lower plate of the condenser (see Fig. 2). Figs. 3 (*a*), (*b*), and (*c*) show successive alterations to the shape of the

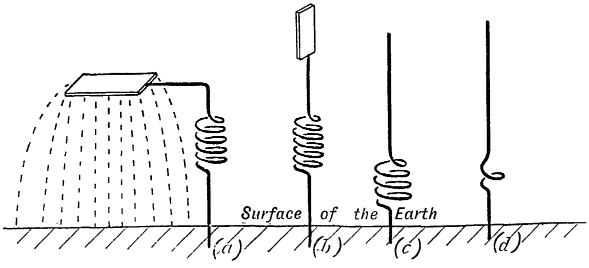

FIG. 3.

upper plate and its distance from the earth or lower plate, until it has ultimately degenerated into a mere continuation of the wire of which the coil is made. Similarly, by decreasing the

* Kinetic energy $= \frac{1}{2}mv^2$. Energy in spring $= \frac{1}{2}yf^2$.
Magnetic energy $= \frac{1}{2}LC^2$. Electrical energy $= \frac{1}{2}KV^2$.
Frequency $= \sim = \dfrac{1}{2\pi\sqrt{m.y.}}$ or $\dfrac{1}{2\pi\sqrt{KL.}}$

number of turns in the coil (Fig. 3 (*d*)) we decrease its inductance and still further increase the frequency. The limit is reached when our oscillatory circuit has become a vertical straight wire. The upper part of the wire acts as one plate of the condenser, while the lower part fulfils the functions of the coil. The two functions of the wire gradually merge into one another, and only at the extreme ends can the wire be considered either a pure condenser or a pure inductance. A plain vertical wire will therefore have a natural frequency of oscillation, which can be shown to be seventy-five million divided by the height of the wire in metres. This gives the number of complete double swings per second. The natural frequency of a given vertical wire can be reduced by increasing its inductance—*i.e.*, by inserting a coil of wire at its foot as in Fig. 3 (*c*).

To set up oscillations in any of these circuits, the circuit is broken by means of a spark-gap, and the condenser is connected to the high-

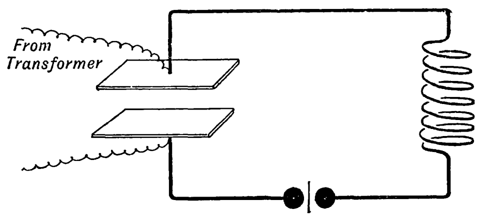

FIG. 4.

tension terminals of a spark coil or of an alternating current transformer (Fig. 4). This charges up the condenser and raises the potential difference across the spark-gap to a very high value (5,000 to 30,000 volts) many times per second. If the distance between the spark balls be suitably adjusted, the tension in the air-gap will succeed in breaking it down, and the oscillatory circuit will be completed through the spark. The condenser will discharge through the spark and the inductance, and the electricity will surge backwards and forwards in the way we have already considered.

This must all occur during the very short interval that the spark-gap is bridged by the spark, for when the spark ceases the circuit is opened, and no further oscillation **is** possible until the condenser is once more charged, and the potential difference raised once again to the value required to break down the spark-gap.

Hosted by Google

In Marconi's earlier stations the aerial was set oscillating in this way (see Fig. 5). This was called working with a plain aerial, but is now more generally known as a pre-charged aerial. It is little used at the present time.

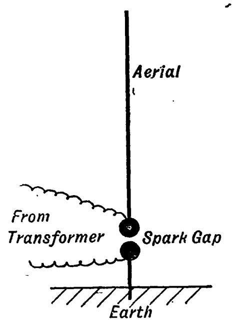

FIG. 5.

There is an important difference between the oscillations set up in such a circuit as that shown in Fig. 4, and that set up in the aerial in Figs. 3 (*d*) and 5. In Fig. 4 the disturbance is confined to the immediate neighbourhood of the circuit, and the energy alternates between the magnetic field of the coil and the electrostatic field of the condenser with only one source of loss, viz., that due to the resistance of the circuit. In Figs. 3 (*d*) and 5, however, where the

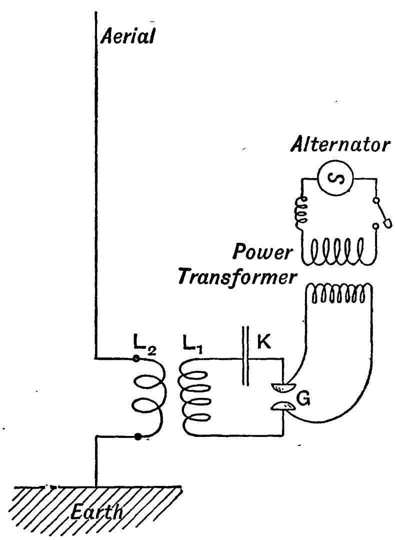

FIG. 6.

electric and the magnetic fields alternately occupy the same space, the disturbance is more far-reaching, and the train of oscillations occurring with each spark causes a train of waves in the ether to spread out from the aerial in all directions, like the ripples from that point in a lake where a stone has just entered the water. These pulses or waves carry with them, and are the manifestations of, energy, so that the oscillations in the aerial are damped out more rapidly than would be the case were the only loss of energy that due to resistance.

The arrangement shown in Fig. 5 was soon given up in favour of another arrangement known as a coupled aerial, and shown in Fig. 6. This figure may be taken as representing diagrammatically the sending apparatus of almost every radio-telegraphic station in commercial use at the present day. Here we have two oscillatory circuits—one called the primary, containing an inductance, L_1 a condenser, K, and a spark-gap, G, exactly as in Fig. 4; and the other the aerial itself with a coil or inductance, L_2 at the base exactly as in Fig. 3 (*c*). The coils L_1 and L_2 are coupled together—*i.e.*, they are placed so near that the magnetic field produced by a current in L_1 passes to a certain extent through the turns of L_2. L_1 and L_2 constitute the primary and the secondary of a transformer, and the oscillatory currents occurring in L_1, whenever a spark passes at G, induce electromotive forces in L_2, and set up oscillations in the aerial, *especially if the two circuits are adjusted to have the same natural frequency.* This latter operation is called tuning the circuits, and is exactly analogous to the adjustment of a violin string until it has the same natural fre-

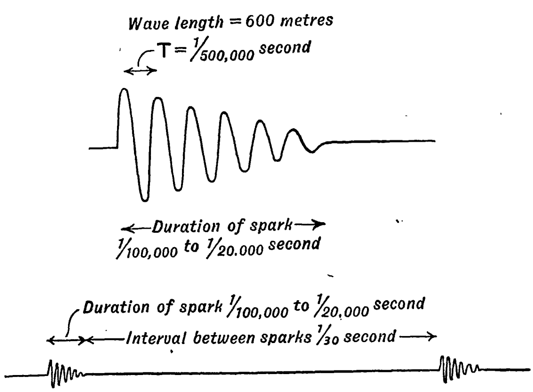

FIG. 7.

quency of vibration as the corresponding string in the piano.

Each spark causes a damped oscillation in the circuit L_1, K, G (Fig. 6), and this causes a somewhat similar oscillation in the aerial, from which electro-magnetic waves are radiated in every direction over the earth's surface. The total time occupied by the aerial in sending out the

Hosted by Google

train of waves may be from $\frac{1}{100000}$ to $\frac{1}{5000}$ of a second, as shown in Fig. 7, where the oscillatory current is represented as making about six complete oscillations before being completely damped out. Nothing further will happen until the next spark occurs, which in Fig. 7 is supposed to be one-thirtieth of a second later.

Let us now turn from the sending apparatus and follow the damped train of waves which, as the result of the spark, has been sent out from the aerial, and is travelling in all directions through the ether with the velocity of light—viz., 300,000 kilometres per second (see Fig. 8).

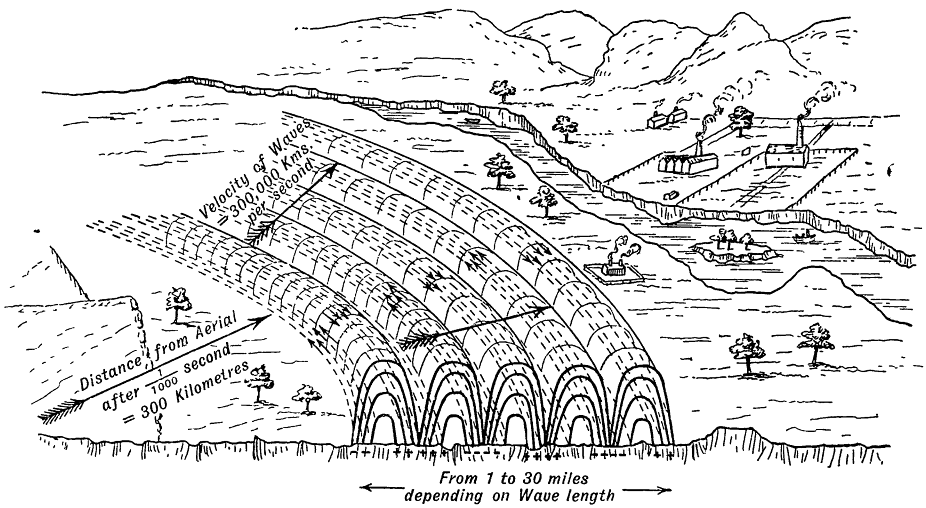

FIG. 8.

Every vertical conductor, whether lightning conductor, rain-water pipe, or radio-telegraphic aerial, encountered by the electro-magnetic wave has electro-motive forces induced in it, and extracts a little energy from the wave. If the vertical conductor, which we have already seen to be an extreme form of oscillatory circuit, be tuned so that its natural frequency is equal to the frequency of the passing wave, the effects of successive impulses will be cumulative, and the oscillatory current produced in it will be large compared with the current which would be produced were the aerial not tuned to the received wave.

To complete the communication between the two stations, it only remains to detect the presence of this minute high-frequency current in the receiving aerial. The most sensitive and probably the most widely used method is shown diagrammatically in Fig. 9. The currents in the coil L_3, at the foot of the aerial, induce currents in the circuit, K, L_4, which is tuned to have the same frequency and loosely coupled with L_3. The tuning is carried out by means of the adjustable condenser, K, which is varied until the best results are obtained. After what has been said it will be readily understood that in transferring the energy from the aerial to the loosely-coupled tuned circuit K, L_4, there will be a weeding-out of all electro-magnetic disturbances which have not the correct frequency.

The detector shown is of the mineral contact

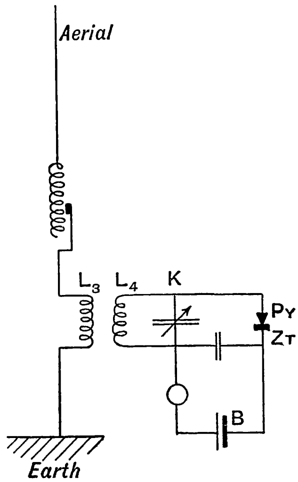

FIG. 9.

type, consisting simply of a piece of zincite in contact with a piece of pyrites. Many other minerals can be used, but nothing seems to exceed these two in sensibility. A telephone receiver is placed in series with the detector

Hosted by Google

across the terminals of the condenser, *K*. The telephone-receiver is shunted by a condenser of such a capacity that it acts as a conductor to the high-frequency oscillations, enabling them

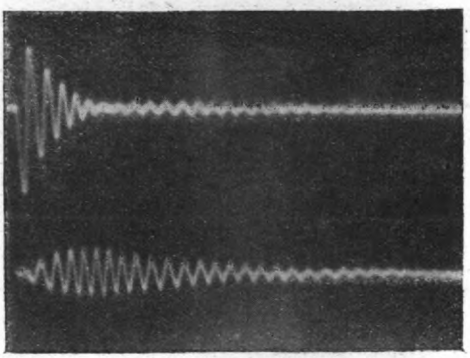

FIG. 10.

to pass through the detector without passing through the highly inductive telephone-receiver; to currents of telephonic frequency it must act as an insulator, thus forcing them to pass through the telephone-receiver. The cell, *B*, is sometimes used to improve the action of the detector, but it is not essential. Whenever high-frequency current passes through the detector, the point of contact is heated, thermal electromotive forces are produced, and a small current is sent through the telephone-receiver.

This current ceases as soon as the point of contact returns to its normal temperature. The sounds thus produced in the telephone-receiver constitute the signal.

Having thus glanced at the receiving station, let us now return to the sending station, and

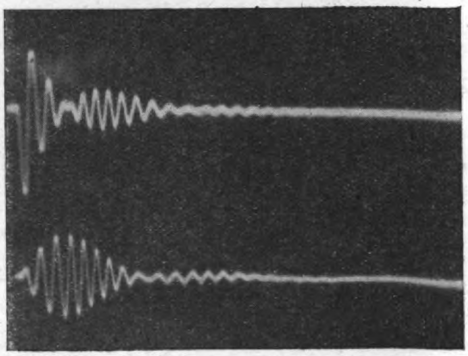

FIG. 11.

consider the various points a little more in detail. With the ever-increasing number of radio-telegraph stations, it is essential to avoid, as far as possible, interference with other stations, and since the waves emitted by an ordinary aerial radiate equally in every direction over the earth's surface, the receiving apparatus should be very discriminating and respond to those waves intended for it, while remaining relatively unaffected by waves possibly far more powerful, but sent out by other aerials. To make this possible it is essential that the waves sent out by every station should be of such a nature that discrimination is possible.

Now we have seen that to discriminate against any wave which we do not wish to receive, we must tune our receiving apparatus—both aerial and secondary circuit—to some other frequency, either higher or lower, than that of the disturbing wave. If the sending station with which we wish to communicate is sending with exactly the same wave-length as the disturbing station, we shall tune out both stations at the same time, unless one is much stronger than the other, but

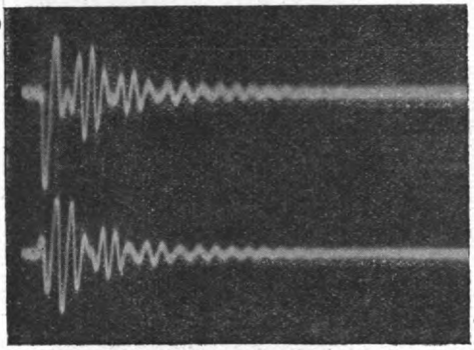

FIG. 12.

if the wave-lengths differ it may be that, when tuned up to the required station, the interfering station is tuned out—*i.e.*, if not inaudible it is so soft as to cause no trouble. The sharpness of tuning which can be obtained, or the amount by which the two sending stations must differ in wave-length to allow of the tuning out of one of them, depends entirely on the nature of the train of waves sent out as the result of each spark. If it be a well-sustained train—*i.e.*, if the damping or decrement be small—very sharp tuning will be possible, but if it be very rapidly damped out the disturbance will be more of the nature of an explosive shock than of a train of waves, and it will be found impossible to tune it out. A plain or pre-charged aerial must always be a great offender in this respect, for, whatever the nature of the subsequent train of waves, it always commences with a sudden shock of no definite frequency, whereas in the

Hosted by Google

coupled aerial the shock is confined to the primary circuit and the oscillatory current is gradually built up in the radiating aerial.

Consider now the effect of varying the coupling between the two coils, L_1 and L_2, in Fig. 6. If the coupling be loose—*i.e.*, if the coils be far apart—the transfer of energy from the primary circuit to the aerial will be slow, the reaction of the aerial on the primary circuit will be small, and the currents will be as shown in the oscillogram, Fig. 10, where the upper curve represents the current in the primary circuit, K, G, L_1, and the lower curve that in the aerial. The lower curve will, therefore, indicate the nature of the train of waves sent out by the aerial. The transfer of energy being slow, much of it will be dissipated in the spark-gap, and it is impossible with such an arrangement to transfer more than about 30 per cent. of the primary energy to the aerial. If we try to improve the efficiency by coupling the coils L_1 and L_2 more closely, and thus hastening the transfer of energy to the aerial, a new difficulty arises. When all the energy has been transferred to the aerial the current in the primary oscillatory circuit will have fallen to zero, but the primary circuit is still closed through the hot spark-gap, which does not instantly lose its conductivity, and the aerial coil L_2 will now act as the primary of the transformer, and L_1 as the secondary, and the energy, or what remains of it, will surge back into the circuit, L_1, K, G. This phenomenon is well known in all coupled oscillatory systems, and can be easily shown by suspending two pendulums from the same flexible support. The oscillograms, Figs. 10, 11 and 12, were taken under identical conditions, except that the coupling was made successively closer. The lower curve of Fig. 12 shows, then, the nature of the waves emitted by the aerial with tight coupling. There is no sustained train of waves of one definite frequency, but a succession of surges or beats. A similar result would be obtained from two aerials side by side, sparking simultaneously, but of different wave-lengths. When we remember that the receiving apparatus is really a harmonic analyser, picking out and responding to waves of its own natural frequency, it is easy to see that the best result will not be obtained when the receiving aerial has the same natural frequency as the sending aerial. If the magnitude of the signals received, as the natural frequency of the receiving apparatus is altered, be plotted, curves are obtained similar to those in Fig. 13, where each curve refers to a certain given coupling in the sending apparatus.

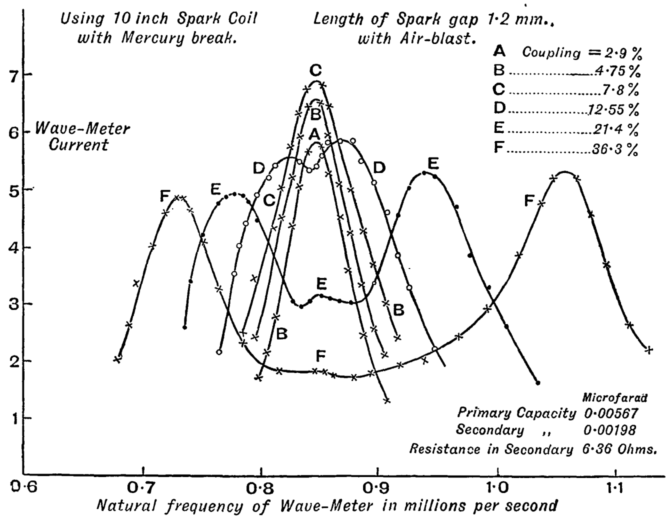

Fig. 13.

With the ordinary spark-gap it is thus seen to be impossible to increase the coupling much above 7 or 8 per cent. without sacrificing sharpness of tuning, and thus causing undue interference with stations working at other wave-lengths. Apart from the question of interference there is little increase of efficiency to be obtained by increasing the coupling beyond this value. Most stations are working at present in this way with loose coupling, and consequent low efficiency.

In Fig. 13 it will be noticed that when the coupling is tight, the aerial oscillation contains waves of three definite frequencies

Hosted by Google

—one high and one low, corresponding to the constituents of the beats — and one of the natural frequency of the aerial alone. This last shows that during a part of the time

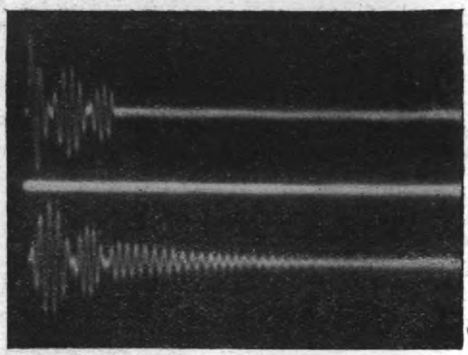

FIG. 14.

the aerial oscillated freely, uncoupled from the primary circuit. The reason for this can be seen from the oscillogram, Fig. 14. In the experiment to which Fig. 13 refers, the spark-gap was exposed to an air-blast, so that whenever the amplitude of the current in the primary oscillating circuit was small, there was a tendency for the air-blast to remove the column of hot air and metallic vapours, and thus extinguish the spark. This will obviously occur at a moment when all the energy is oscillating in the aerial, and will prevent it surging back into the primary circuit. The aerial will now continue to oscillate at its natural frequency until the energy has been radiated or dissipated. In Fig. 13 not only was there an air-blast, but the electrodes were comparatively large and the spark-gap short,

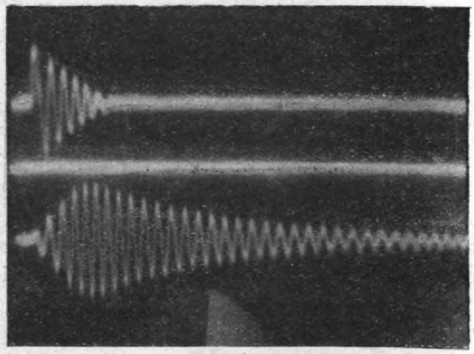

FIG. 15.

so that no part of the spark was far removed from a large mass of cold metal tending to cool the heated air, and condense the metallic vapour, and thus lower the conductivity of the spark. This quenching of the spark was discovered in 1906 by Professor Max Wien, and was afterwards taken up by the Telefunken Company, who are using a form of gap which has a strong tendency to quench. If the quenching of the spark is perfect, the currents will be as shown in oscillogram, Fig. 15. The gap acts as a very quick-acting minimum-current cut-out, and opens the primary oscillating circuit at the first opportunity—viz., when all the energy has been transferred to the aerial. The time during which the two circuits are coupled is very short, the loss in the spark-gap is reduced, and the major portion of the energy oscillates freely in the aerial and is radiated as a damped train of waves at its natural frequency. In this way it is claimed that 75 per cent. of the output of the alternator is transferred to the aerial.

It is obviously advantageous to shorten the

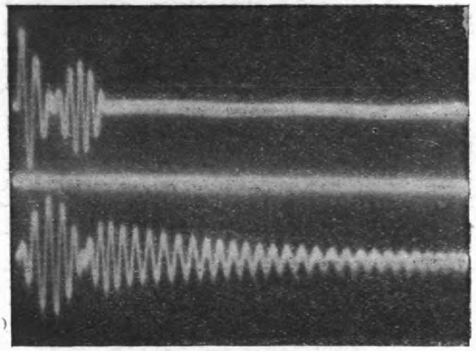

FIG. 16.

duration of the spark as much as possible by tightening the coupling between the coils L_1 and L_2, and thus hastening the transfer of energy to the aerial. If this be overdone, however, the gap will fail to quench at the first minimum, and we may get the conditions shown in Fig. 16, or even Fig. 14, with a great loss both in efficiency and in sharpness of tuning. Wien first obtained quenching by the use of very short spark-gaps, and this is the method used by the Telefunken Company, although other methods have since been discovered. The spark is made to occur between the parallel faces of discs of copper or silver, placed about $\frac{1}{100}$ in. apart, the discs being separated by thin annular rings of mica, which also serve to shut the sparking spaces off from the air. The number of these discs in series depends on the voltage and power required. This form of gap is undoubtedly complicated and expensive, not only in first cost but also in

Hosted by Google

upkeep, and the increased efficiency is obtained by the sacrifice to a certain extent of reliability and simplicity.

In addition to the interference from other stations, there are the atmospheric disturbances

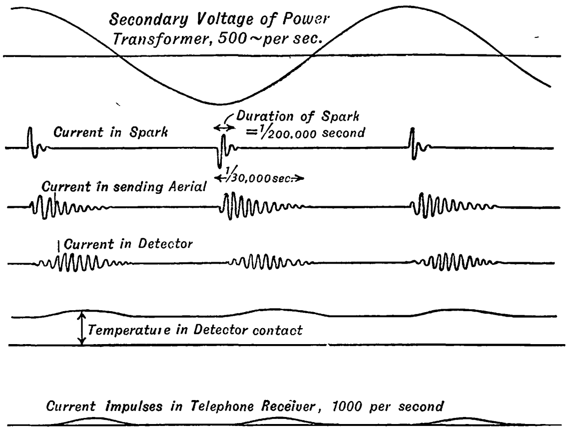

FIG. 17.

due to lightning flashes somewhere on the globe. Each flash sends out a powerful electro-magnetic pulse of explosive suddenness. It is practically impossible to tune these out, as any frequency they may have is quite indefinite, and they are often much louder than the signals being received. It is here that great improvements

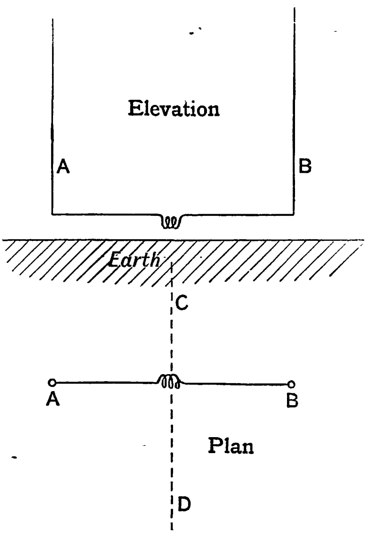

FIG. 18.

have been made by giving the signals a clear musical note, easily distinguishable from the crackling noises due to atmospheric disturbances. A study of Fig. 17 will show that the pitch of the note heard in the telephone-receiver depends entirely on the number of sparks per second, while the purity of the note depends on the regularity of the sparks. By using a high spark frequency—*i.e.*, a large number of regularly occurring sparks per second—a clear musical note is obtained, but, contrary to expectations, the telephone-receiver shows no greater sensibility than with the low spark frequency.

By using an alternating-current generator giving 500 cycles per second as the source of supply, and adjusting the voltage or gap until we get a spark every half-cycle, a pure note, with a pitch of 1,000 will be obtained—that is, a high, piping note easily distinguishable from other sounds. To ensure regularity the gap must be kept cool, and the after-effects of each spark quickly removed. With the ordinary long gap this can be done by means of an air-blast or by making the electrodes in the form of large discs, and revolving them by means of a motor, as is done by the Marconi Company in their large stations. In the short, quenched spark-gaps the spark has to be quenched about $\frac{1}{200000}$ second after it has jumped across, so that after $\frac{1}{1000}$ second the gap should have lost all traces of the spark.

The quenching action has thus to play a double part, the first affecting the nature of each spark and the resulting oscillation, and the second affecting the regular succession of sparks.

One cannot but be struck by the inefficiency

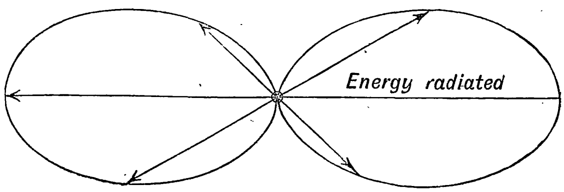

FIG. 19.

of radio-telegraphic communication when looked at from the point of view of the transmission of energy. In some recent experiments made on ships of the United States Navy, it was found that at a distance of 500 miles the current in the sending aerial had to be 30 amperes to produce in the receiving aerial the current of 40 micro-amperes, which was found to be necessary for good signals. This great loss is mainly due to the world-wide radiation of the energy from the sending aerial. Seeing that the electro-magnetic

wave is of the same nature as light, one would naturally suggest putting a reflector behind the aerial so as to throw the ray forward. It must be remembered, however, that a reflector must be large in comparison with the length of the wave, so that whereas a reflector as large as the head of a pin is quite efficient for light with a wave-length of $\frac{1}{2000}$ millimetre, an efficient

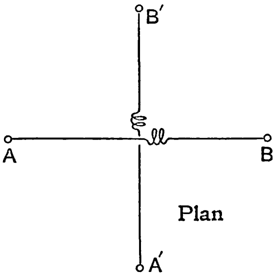

FIG. 20.

reflector for a wave-length of 6 kilometres, or even of 300 metres, is out of the question. Attempts are being made, however, to direct the electro-magnetic waves in the desired direction. Two methods have been successfully employed—one due to Bellini and Tosi, the other to Marconi. The former is easily understood, and is based on well-known principles. The reasons for the directive action of Marconi's bent antenna have been much discussed, and several possible theories have been worked out. In the simplest form of apparatus employed by Bellini and Tosi two vertical antennæ are employed, joined at their lower ends by a horizontal insulated wire, in the middle of which is inserted the secondary coil of the sending transformer (Fig. 18). When the A antenna is charged positively the B antenna will be charged negatively, so that when A is sending

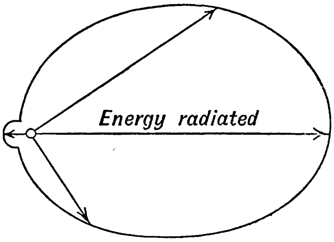

FIG. 21.

out a wave-crest, B will be sending out a wave-trough, and *vice versa*. Anywhere on the line C, D these two waves will neutralise each other, but if the distance A, B be rightly chosen the crest emitted by A will arrive at B just as B is also emitting a crest. At the same moment A is emitting a trough, and the trough which half a period before was emitted by B will just have arrived at A. Hence, anywhere in the line A, B, produced in either direction, the waves emitted by the two antennæ are additive.

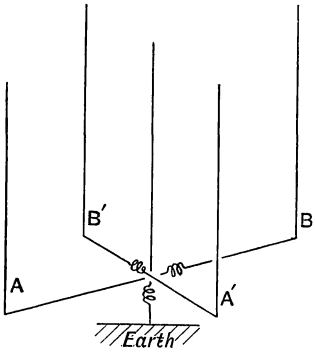

FIG. 22.

A diagram representing the energy radiated in various directions will be somewhat like Fig. 19. With this arrangement the radiation is equally powerful, both in the desired and in the opposite direction. If we wish to alter the direction, we must either arrange to rotate the whole aerial, or we must duplicate the whole arrangement at right angles. There will then be four vertical antennæ used in diagonal pairs (Fig. 20). The primary coil of the sending transformer is capable of rotation, so that it can influence either the secondary coil of A, B, or that of A^1, B^1, or partly one and partly the other.

In this way the line of maximum radiation can be rotated at will. Bellini and Tosi have gone a step further, however, and have done away to a large extent with the backward radiation as shown in Fig. 21, which shows the actual results obtained. This has been attained

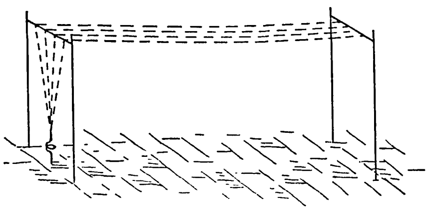

FIG. 23.

by erecting an ordinary vertical antenna halfway between the outer antennæ—*i.e.*, immediately over the transformer coils, Fig. 22. This antenna is earthed through a separate secondary coil, which is acted on by the same primary as

Hosted by Google

the other secondary coils, but the best results are obtained by slight modifications, into which we shall not enter.

The radiation from this central antenna will be uniform in every direction. If now, just as the crest of a wave, emitted by the central antenna, reaches the outer antennæ *A* and *B*, the former is emitting a trough and the latter a crest, the radiation in the direction *A*, *B* will be strengthened, and that in the direction *B*, *A* weakened. The whole action depends on the correct magnitudes and phase relations of the waves emitted by the central and outer antennæ.

With the Marconi bent antenna (Fig. 23) the results obtained are somewhat similar, although not so pronounced. The maximum radiation is in the opposite direction to that in which the upper horizontal part of the antenna points, and this direction cannot be altered, but must be decided when the antenna is erected.

DISCUSSION.

Mr. James Swinburne, F.R.S., in opening the discussion, said the author was a very bold man, who had tackled the problem of trying to explain the principles of wireless telegraphy to a non-specialised audience in an hour, but he had succeeded very well indeed in his difficult task. In dealing with the question of the Marconi system of directing, the author had stated that it was very difficult to say how it worked. In Fig. 18 two aerials, A and B, were shown, with the induction coil in the middle. To complete that, it was possible to connect the tops of the aerials, a complete circuit then being obtained. If one side, B, was then removed, an imperfect model of the Marconi arrangement was obtained, which would tend to send the messages along both directions, but better in the direction on which the side was more perfect. He could not help thinking that that was a popular explanation of the directive action of the Marconi method. The author had also pointed out how the other arrangements sent out energy in special directions, and he would like to ask Mr. Howe whether there was not perhaps some slight fallacy underlying his assumptions. It did not follow usually that because it was impossible to pick up energy where there was interference, any less energy was sent out from the aerial, and that therefore the efficiency in the other directions, or the efficiency as a whole, was increased. That was a matter which he thought was worthy of consideration. In his opinion the author had been a little hard on wireless telegraphy when he referred to its inefficiency, because, personally, he could not help feeling that wireless telegraphy was one of the most efficient means of communicating generally in all directions that man had invented. If communication was established between two fixed points, *a* and *b*, it was natural to expect efficiency; but for communicating in all directions wireless telegraphy had an extraordinary property, namely, that the energy varied substantially inversely as the distance and not inversely as the square of the distance. The energy in the case of incandescent lamps or any other light varied as the square of the distance and not as the distance, the result being that wireless telegraphy was enormously more efficient than the sort of radiation generally dealt with. In another form of communication, such as induction telegraphy, which was proposed at one time and worked out to some extent by Sir Oliver Lodge, a method was obtained which varied inversely as the cube of the distance, and fell off therefore very quickly indeed. When one realised what wireless telegraphy had done it was only possible to come to the conclusion that it was not inefficient, but, on the other hand, that it was one of the most extraordinarily efficient means of general communication that had hitherto been invented.

Mr. W. Duddell, F.R.S., thought that one of the main features of recent progress in wireless telegraphy was that by means of an enormous number of experiments carried out by many investigators, success has been obtained in getting a very much better note than had been used in work on telephone-receivers, which had rendered it possible to read signals in spite of atmospheric disturbance. One of the greatest difficulties in connection with wireless telegraphy at the present day was atmospheric disturbance. Even in the latitudes of this country, where lightning at the present time of the year was comparatively rare, there was an enormous amount of atmospheric disturbance every evening, which took the form of irregular cracks. It seemed quite impossible to tune them out in any way. The author had stated that those cracks had no apparent frequency of their own. Personally, he did not think that was quite accurate, because it appeared that the longer the wave-length that the aerial was adjusted for, the more the system suffered from atmospherics, as if the atmospheric disturbances themselves were irregular disturbances, of which the greater number had a long wave-length, so that more of them were heard if the system was adjusted for long wave-lengths. The old form of crackling spark sounded so much like the click of the atmospheric, that dots were put into the Morse alphabet, so that it was easily possible to turn d's into b's. With the quicker spark a more musical note was obtained, on which it was possible to fix one's attention, and if one was expert it was possible to read it right through even under very considerable atmospheric disturbance. He wished the author had carried the question of atmospheric trouble a little further, and given the latest results obtained with regard to stopping-out by special devices some of the more pronounced atmospheric disturbances. He believed that great success had been achieved in that direction within the last year by Mr. Marconi.

Hosted by Google

Mr. A. C. Brown asked the author, in his reply, to state what, in his opinion, were the possibilities of wilful interruptions of wireless telegraphy in times of war. After carefully considering the subject, he had come to the conclusion that the first effect obtained under such circumstances would probably be the sudden cessation of all effective wireless telegraphy. It seemed to him that if a ship was sent out equipped with apparatus as powerful as the most powerful stations that it wished to interrupt, with the means of continuously varying the inductance and capacity in such a way as would first produce long wave-lengths, and then successively smaller wave-lengths, and repeating that mechanically by turning a wheel, it would be possible to interrupt any wave-lengths capable of being used in practical wireless telegraphy. It might be necessary to tune exactly to a wave-length in order to read it, but it was not necessary to know the wave-length in order to interrupt it. The point was, he thought, an important one, because so much depended on wireless telegraphy during war.

Colonel C. Napier Simpson asked whether, on a battlefield which covered only a small distance, it would be possible for an enemy so to disturb the wireless telegraphy apparatus that it would be absolutely useless. There were one or two points in connection with wireless telegraphy on which he was very much in the dark. For instance, he understood that if two ships were 500 miles apart, and were on north and south courses, they would easily be able to pick up wireless signals from each other, whereas they were not able to do so if they were only 200 miles apart, and their courses were east and west. He also understood that wireless messages sent to some places at night were easily received, while in the daytime it was almost impossible to communicate by means of wireless telegraphy with the same places. On the other hand, he understood that some stations could easily receive messages by day and not at night.

Professor Osborn Howe, in reply, said that Mr. Swinburne had pointed out that the Marconi directed aerial could be explained roughly by means of the Bellini and Tosi method. As a matter of fact, that was the line upon which the most recent mathematical investigations had gone. The most recent mathematical explanation had considered that between the open end of the Marconi aerial and the ground fictitious aerials could be imagined, and it was by means of assuming those fictitious aerials, in which the induced currents of the earth came into play, that the most reasonable explanation of the Marconi aerial had been given. The question of whether the Bellini and Tosi method was more effective in the maximum direction than a plain aerial was open to a certain amount of discussion. Bellini and Tosi had given results to show that it was, but personally he thought that in order to make comparative tests it would be better to compare the Bellini and Tosi aerial with an ordinary aerial on which the same amount of money had been spent; for instance, instead of setting four aerials up at the corners of a field, by putting the amount of the additional capital thus expended into a much larger aerial in the middle of the field, the directive effect would be lost, but it was quite possible that more energy would be obtained in the maximum direction than with the Bellini and Tosi method. The Bellini and Tosi method did away to a large extent with interference with other stations, and also with the danger of being picked up by other people. As Mr. Swinburne pointed out, electromagnetic wave radiation was far more efficient than ordinary light radiation, because as he (the author) showed in one of the figures, the waves were not spreading up and down except to a limited extent. The radiation was practically between two parallel planes in all directions. Therefore, the space occupied by the wave only increased as the distance, whereas, if it was spread out spherically the space occupied by the energy would vary as the square of the distance. Mr. Duddell had, to some extent, misunderstood the remarks he made in the paper. He did not mean to convey that atmospherics had no frequency, and it would be noted that he said in the paper: "It is practically impossible to tune these out, as any frequency they may have is quite indefinite"—he might also have said "unknown." Most of the atmospherics had a frequency, but one was quite in the dark as to what they would be and when they were coming, and they were probably all different, so that any frequency they might have was quite indefinite and unknown. He believed a lot had been done in the direction of stopping them out. In the trans-Atlantic work, he believed that great success had been achieved by using two Fleming valves in parallel, adjusted to have different sensitiveness, so that the by-pass valve was not quite sensitive enough to shunt the signals that one desired to receive. The signals desired had to come through the working valve when the sensitiveness could be adjusted, but if an atmospheric suddenly came the powerful aerial then succeeded in breaking down the additional resistance in the by-pass and was shunted. He agreed with Mr. Duddell that a lot of work had been done on the subject, and he believed the Marconi Company were meeting with great success in that direction. Mr. Brown had referred to the question of spoiling the enemy's wireless telegraphy in time of war. Personally he thought it was rather difficult to say what would happen in time of war; the things that happened in times of peace were quite bad enough. He believed various arrangements had been devised for running up and down the scale and blazing away at full power on the chance of spoiling wireless messages. It was a fact, as Colonel Simpson had stated, that wireless signals did travel better from north to south than from east to west, but he did not believe any explanation had yet been given why they did so. It was also a fact that, as a rule, electro-magnetic waves could travel with far less absorption at night than at day. Wireless stations

Hosted by Google

would, as a rule, guarantee a longer range at night than by day, but the night range was very uncertain. The day range seemed to be more or less fixed, and there was not the same variation in the day range that there was in the night range. Colonel Simpson also referred to the irregularity in wireless stations, one station seeming to work all right, while another station a little way off could not work at all. Recently it was possible to work quite well between Ireland and one station in America, but not to another station, although the distance between the two American stations was not great; there was some local obstruction in the way, some etheric fog bank, which absorbed the atmospheric waves. The explanation that was usually given for the difference between day and night working was that the ultra-violet light from the sun ionised the air, making it partly conducting, and if the electro-magnetic waves were passing through a conductor and not through a perfect dielectric the energy would be absorbed. That, however, could not be a perfect explanation; it did not account for the peculiarities that occurred during the night. It was a fact that if one listened in England to the messages received from America it was possible practically to hear the sun rise and set on the Atlantic. During the day the signals were almost inaudible, and as darkness fell across the Atlantic the signals gradually became louder and louder.

Colonel Simpson said he understood there were stations in Africa in which the reverse phenomenon occurred, the hearing being much better by day than by night.

Professor Osborn Howe said the statement was quite new to him that any station worked regularly better by day than by night; as a general rule, the night sending was better than the day, but he was afraid he could not explain why that was the case. He believed that if the enemy were clever enough they could prevent wireless telegraphy working. If they had powerful wireless apparatus and set themselves to do so, there was nothing to stop them from absolutely blocking every station within a certain radius. For instance, if anybody at the Eiffel Tower wished to prevent wireless messages being sent from England, France, or Germany, for twenty-four hours, he did not think it would be very difficult for them to do so. They would simply run up and down the scale and blaze away at full power, and he believed that would stop all wireless communication within several hundred miles.

The Chairman (Sir William H. White), in proposing a cordial vote of thanks to the author for the wonderful epitome he had given of the science of wireless telegraphy, said that he was primarily guilty of the fact that the author had been asked to deliver a paper before the Society. At the Portsmouth meeting of the British Association, Professor Howe gave a most admirable address on the advances made in wireless telegraphy, accompanied by a demonstration which he wished could have been repeated that evening, because it was one of the most effective demonstrations he had ever seen. Not only did the author on that occasion capture the time signal sent out at noon from Wilhelmshaven, but he also unintentionally captured a local wireless message in quite a different tune that was being sent from Portsmouth to the Admiralty. Although personally he was not an expert in the subject, he could distinguish quite clearly between the messages that were being sent simultaneously, the one from Portsmouth and the other from Wilhelmshaven. With regard to the question of interference with wireless messages in times of war, that was actually done during the war between Japan and Russia in the Far East, when he believed a Japanese operator took a dictionary and proceeded to reel off as many pages as he could on his instrument. The Russian ships, which hoped to receive wireless messages, did not get any at all. That he believed could always happen. It represented an expenditure of energy which was perhaps less harmful than other expenditures of energy that occurred in time of war.

The resolution of thanks was carried unanimously, and the meeting terminated.

CORRESPONDENCE.

RESPECT FOR LABOUR IN INDIA.

I am solicitous to record in our *Journal* a brief but emphatic protest, so far as India is concerned, against a very widely-circulated, sweeping statement recently made by the Rev. Lord W. Gascoyne Cecil, to the effect that the difference of position between the working man of the East and of the West is not solely due to a difference in their wages, but because physical labour in the East "is universally despised." The direct opposite is the fact in India—India of the Hindus—unless where European industries, and concomitant English ideas of respectability, now prevail. There is a beautiful saying among Hindus: "The hand of the workman [even the dyer's] in his work, is always pure"; and it is a very beautiful observance among them, in the streets and high roads, to give way to a working man *in his work*. From the day I first noted it, I have myself conformed with the practice, which with the Hindus is a rite; and when in this country my so doing has haply been observed, as by some working man carrying an unmanageable weight, his instant outburst of warm-hearted thanks has ever proved an all-sufficient proof for me of the superiority of Eastern to Western civilisation in its sentiment toward labour.

It is also a pity that the writer referred to should seek to identify Christianity with civilisation. Once it was so with me; and arguing with the venerable, white-bearded Arab pilot who was taking the

Hosted by Google

Honourable East India Company's s.s. "Ajdaha" up the Euphrates to the bombardment of Mohammerah [and who talked all the while of Abraham, and Isaac, and Ishmael, as if they were still living among us], on the evidence afforded by the superiority of Western over Eastern civilisation, of the practical superiority of Christianity over all other religions, he, pointing to the cannon and the heaped shot and shell about us, simply asked: "Are these things in which you so excel us of the inspiration of God or the devil?" We argued no more that day. But the great guns overwhelmingly prevailed in the bloody work whereto they were so expertfully and so well-approvedly piloted by this ancient autochthon, "out of Ur of the Chaldees."

AEROPLANE EFFICIENCY.

With reference to Mr. Berriman's very interesting paper in the *Journal* of December 1st, may I indicate the following points:—

(1) "Frictional resistance formula."—In my papers in the *Aeronautical Journal* I have given the value: $R = 0 \cdot 000015\ AV^2$ for single surfaces (R in lbs., A in sq. ft., V in feet per second). This became $0 \cdot 00003\ AV^2$ for double surface, or $0 \cdot 000014\ AV^2$ (V in miles per hour), as compared with Mr. Berriman's value, $0 \cdot 000018$.

(2) *Re* "Efficiency."—This expression originated with Turnbull. "Drift-ratio" conveys the meaning most satisfactorily.

(3) *Re* "Angle" and methods of measuring it.—Gliding experiments (*vols-planés*) lead to fairly correct values when worked out on the basis of minimum potential. Lanchester has overlooked the fact that an aeroplane must run in the direction of least resistance. With cambered surfaces the gliding angle may be equal to or a little more than the "deflection angle."

HERBERT CHATLEY.

OBITUARY.

GEORGE WEDLAKE.—Mr. George Wedlake died suddenly on the 22nd January at the age of sixty-three. After spending some time as a young man in the West Indies, Mr. Wedlake returned to London and devoted himself to journalism. He was a leader-writer on the *Echo*, and financial editor of the *Star*. He was afterwards appointed editor of *Talk*, and on the demise of that journal he became editor of *To-day*, *Madame*, and the *Imperial Review*. In 1905 he was elected a member of the Royal Society of Arts, and since that date he was a regular contributor to the *Journal*. A man of wide experience and varied interests, he kept himself well informed of all developments in the industrial world, and this knowledge was reflected in his "Home Industries," which have been a constant feature of the *Journal* for the last seven years.

GENERAL NOTES.

1911 FROM THE BANKER'S POINT OF VIEW.—When presiding, last week, at the annual ordinary general meeting of the shareholders of the London County and Westminster Bank, Lord Goschen reviewed the year 1911 from the banker's point of view. While not devoid of a certain amount of anxiety, upon the whole it had not been an unfavourable period. The trade of the country had progressed satisfactorily, showing an increase both of exports and imports. Money rates had been favourable to trade, moving within narrower limits than in 1910. The situation abroad, during the summer and autumn of last year, had caused considerable anxiety to bankers, and the disturbed state of the political atmosphere had called for extreme caution in financing commitments abroad. In spite of these troubles, however, the bank had been able to do very satisfactory business during the year, and to declare a dividend of 21¼ per cent. Sir Edward Holden, also, was able to assure the shareholders of the London City and Midland Bank that, although it had been necessary to write off from reserve funds £200,000 to meet the depreciation in securities, the surplus profits for 1911 had been very satisfactory indeed, and more than sufficient to balance this depreciation.

THE PRODUCTION AND CONSUMPTION OF COAL IN INDIA.—A note on the production and consumption of coal in India has just been issued by the Commercial Intelligence Department in Calcutta, the leading feature of the returns being the remarkable and steady increase of production during the past thirty years. In 1880 the total out-turn of Indian coal was 1,019,793 tons, and in 1910 this had risen by progressive steps to 12,047,413 tons. The Raniganj field in Bengal held the first place as regards production up to 1905, but now stands second to Jhasia. Outside Bengal the most important mines are those at Singareni in Hyderabad. Twenty years ago the total consumption of foreign coal on the railways was about one-fourth of the whole, but since then Indian coal has come more largely into use, in so much that the foreign coal has been largely displaced, the Indian coal representing nearly 99 per cent. of the total consumption on the railways in 1910. So far as the statistics of India itself are concerned, the annual output above and below ground per person employed has increased from 93½ tons in 1905 to 103·8 in 1910; figures, however, it may be observed, considerably below the 264 tons of the United Kingdom, 246 of Germany, and 160 of Belgium. The Indian miner is still to some extent a miner by caprice, and in a year of agricultural prosperity the scarcity of labour becomes acute. Epidemics of cholera and other diseases are not infrequent, and cause a shortage of labour. As the workings get deeper the need of a mining population which specialises in mining will become

Hosted by Google

greater. The use of electricity on the coalfields is extending, though capable of further utilisation, particularly for haulage and pumping, and the employment of mechanical coal-cutting appliances will be necessary where the seams are narrow and remote from the surface.

HOP-GROWING IN FRANCE. — The Minister of Agriculture has lately published the result of an inquiry that has been made concerning the hop-growing industry in France during 1911. From this it appears that although hops were grown in eleven departments, on a total area of 2,742 hectares (6,772 English acres), the cultivation of this plant is very unequally distributed amongst them, and may be considered as confined to four only, viz., Department Nord, 1,085 hectares (2,680 acres); Meurthe-et-Moselle, 522 hectares (1,287 acres); Côte d'Or, 942 hectares (2,327 acres); and Haute-Marne, 110 hectares (272 acres); making a total of 6,566 acres. The average yield per hectare was very variable in the various localities, and was from 1,200 kilos per hectare to 1,800 kilos (9 cwt. 63 lbs. to 14 cwt. 39 lbs.) in the Nord, which may be considered as good. In the Meurthe-et-Moselle districts the average was very low, not exceeding 400 kilos per hectare (3 cwt. 21 lbs. per acre). It was slightly better in the Department of Côte d'Or, being 636 kilos per hectare (5 cwt. 7 lbs. per acre). The quality of the hops produced last year in France is considered excellent.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock:—

FEBRUARY 7.—LEONARD HILL, M.B., F.R.S., and MARTIN FLACK, M.A., M.B., B.Ch., "The Influence of Ozone in Ventilation." LORD SANDERSON, G.C.B., K.C.M.G., Chairman of the Council, will preside.

FEBRUARY 14.—CECIL THOMAS, "Gem Engraving." SIR ARTHUR JOHN EVANS, D.Litt., LL.D., F.R.S., will preside.

FEBRUARY 21.—FRANK WARNER, "Silk." SIR GEORGE BIRDWOOD, K.C.I.E., C.S.I., M.D., LL.D., will preside.

FEBRUARY 28.—H. A. ROBERTS, M.A., "The Relations of Science to Commerce and Industry." PRINCIPAL SIR HENRY A. MIERS, M.A., D.Sc., F.R.S., will preside.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

FEBRUARY 8. — COLONEL SIR THOMAS H. HOLDICH, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc., "The North-Eastern Frontier of India." SIR FREDERIC W. R. FRYER, K.C.S.I., formerly Lieutenant-Governor of Burma, will preside.

MARCH 14.—E. A. GAIT, I.C.S., C.I.E., Census Commissioner for India, "The Indian Census of 1911."

APRIL 25.—WALTER SAISE, D.Sc., M.Inst.C.E., Hon. Member Institute of Mining and Geology, India, A.R.S.M., V.D., "The Coal Industry and Colliery Population of Bengal."

MAY 16.—NEVILLE PRIESTLEY, Managing Director, South Indian Railway, "Indian Railways."

COLONIAL SECTION.

Tuesday afternoons, at 4.30 o'clock:—

MAY 7.—ALAN BURGOYNE, M.P., "Colonial Vine Culture."

MAY 21.—THE HON. J. G. JENKINS, "Australian Railways."

CANTOR LECTURES.

Monday evenings, at 8 o'clock:—

LOUDON M. DOUGLAS, F.R.S.E., "The Meat Industry." Three Lectures.

Syllabus.

LECTURE I.—FEBRUARY 5.—The Bullock and its Products.

LECTURE II.—FEBRUARY 12.—The Sheep and its Products.

LECTURE III.—FEBRUARY 19.—The Pig and its Products.

LUTHER HOOPER, "The Loom and Spindle: Past, Present, and Future." Three Lectures.

February 26, March 4, 11.

NOEL HEATON, B.Sc., F.C.S., "Materials and Methods of Decorative Painting." Three Lectures.

March 18, 25, April 1.

HOWARD LECTURES.

Monday evenings, at 8 o'clock:—

CAPTAIN H. R. SANKEY, R.E., M.Inst.C.E., "Heavy Oil Engines." Four Lectures.

April 29, May 6, 13, 20.

Dates to be hereafter announced:—

F. MARTIN DUNCAN, "The Work of the Marine Biological Association."

JOHN NISBET, D.Oec., late Conservator of Forests, Burma, "The World's Decreasing Timber Supplies."

CHARLES C. ALLOM, "The Development of Artistic Skill in the Applied Arts."

ERNEST KILBURN SCOTT, Assoc.M.Inst.C.E., M.I.E.E., "The Manufacture of Nitrates from the Atmosphere."

Hosted by Google

CHARLES BRIGHT, F.R.S.E., M.Inst.C.E., M.I.E.E., "The Administration of Imperial Telegraphs."

HAROLD COX, "The Interdependence of Morals and Economics."

E. D. MOREL, "British Rule in Nigeria."

GORDON CRAIG, "Art of the Theatre." MISS ELLEN TERRY will preside.

THEODORE E. SALVESEN, "The Whaling Industry of To-day."

PROFESSOR ERNEST A. GARDNER, M.A., "Greek Sculpture."

GEORGE FLETCHER, "Technical Education in Ireland."

MEETINGS FOR THE ENSUING WEEK.

MONDAY, FEBRUARY 5...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Mr. Loudon M. Douglas, "The Meat Industry." (Lecture I.—The Bullock and its Products.)

Royal Institution, Albemarle-street, W., 5 p.m. General Monthly Meeting.

Engineers, at the Institution of Electrical Engineers, Victoria-embankment, W.C., 7.30 p.m. Presidential address by Mr. J. Kennedy.

Chemical Industry (London Section), Burlington House, W., 8 p.m. 1. Discussion on "The Industrial Bursaries Scheme of the Commissioners of the 1851 Exhibition." 2. Mr. J. S. S. Brame, (*a*) "Constant Temperature Heating Apparatus for Explosives"; (*b*) "Experiments on the Decomposition of Nitro-Cellulose." 3. Messrs. W. P. Dreaper and J. G. Davis, "Some Physical Constants of Structureless Cellulose Filaments (Artificial Silk)."

British Architects, 9, Conduit-street, W., 8 p.m. Address by the President.

Victoria Institute, 1, Robert-street, Adelphi, W.C., 4.30 p.m. Rev. Professor James Orr, "The Historicity of the Mosaic Tabernacle."

London Institution, Finsbury-circus, E.C., 5 p.m. Professor A. F. Pollard, "The Evolution of England."

TUESDAY, FEBRUARY 6...Royal Institution, Albemarle-street, W., 3 p.m. Professor W. Bateson, "The Study of Genetics." (Lecture IV.)

Alpine Club, 23, Savile-row, W., 8.30 p.m. Lecture by Dr. A. M. Kellas.

Civil Engineers, 25, Great George-street, S.W., 8 p.m. 1. Mr. D. C. Leitch, "The Water-Supply of the Witwatersrand." 2. Mr. E. C. Bartlett, "Investigations Relating to the Yield of a Catchment-Area in Cape Colony."

Photographic, 35, Russell-square, W.C., 8 p.m. Dr. C. E. Kenneth Mees and Mr. C. Welborne Piper, "On the Fogging Power of Developers. Part II. —Determination of the Solubility of Silver Bromide in Sodium Sulphite and other Solvents."

Zoological, Regent's Park, N.W., 8.30 p.m. 1. Mr. H. G. Plimmer, "Report on the Deaths which occurred in the Zoological Gardens during 1911." 2. Mrs. R. Haig Thomas, "On Experimental Pheasant Breeding." 3. Mr. J. T. Cunningham, "Mendelian Experiments on Fowls." 4. Mr. J. Lewis Bonhote, "A Further Collection of Mammals from Egypt and Sinai." 5. Mr. H. Wallis Kew, "On the Pairing of Pseudo-scorpiones."

Horticultural, Vincent-square, Westminster, S.W., 3 p.m.

WEDNESDAY, FEBRUARY 7...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Drs. Leonard Hill and Martin Flack, "The Influence of Ozone in Ventilation."

Geological, Burlington House, W., 8 p.m.

Public Analysts, Burlington House, W., 8 p.m. 1. Annual General Meeting. 2. Messrs. F. W. F. Arnaud and H. Hawley, "Notes on the Determination of Butter Fat and Cocoanut Oil in Margarine." 3. Messrs. H. Droop Richmond and H. C. Huish, "The Souring of Milk." 4. Mr. E. Hinks, "A Flour Improver."

United Service Institution, Whitehall, S.W., 3 p.m. Lieut.-Colonel G. Le M. Gretton, "The Raising of the National Reserve in a Country District."

King's College, Strand, W.C., 5 p.m. (Lectures on Christian Art.) Miss Gertrude Bell, "The Christian Churches of Western Mesopotamia."

Royal Archæological, at the Society of Antiquaries, Burlington House, W., 4.30 p.m. Mr. J. A. Gotch, "The Original Drawings for the Palace of Whitehall, attributed to Inigo Jones."

THURSDAY, FEBRUARY 8...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Indian Section.) Colonel Sir Thomas H. Holdich, "The North-Eastern Frontier of India."

Royal, Burlington House, W., 4.30 p.m.

Antiquaries, Burlington House, W., 8.30 p.m.

Röntgen Society, at the Institution of Electrical Engineers, Victoria-embankment, 8.15 p.m.

Automobile Engineers, 13, Queen Anne's-gate, S.W., 8 p.m. (Graduates' Section.) Mr. B. W. Ainsworth, "Worm *versus* Bevel Drive."

London Institution, Finsbury-circus, E.C., 6 p.m. Mr. Josiah Booth, "Songs and Ballads of Sir Arthur Sullivan."

Royal Institution, Albemarle-street, W., 3 p.m. Professor A. M. Worthington, "The Phenomena of Splashes." (Lecture II.)

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Rev. D. G. Cowan, "Gotland and its Ruins."

Electrical Engineers, Victoria-embankment, W.C., 8 p.m. Mr. E. H. Rayner, "High Voltage Tests and Energy Losses in Insulating Materials."

Mathematical, 22, Albemarle-street, W., 5.30 p.m.

Concrete Institute, 296, Vauxhall Bridge-road, S.W., 8 p.m. Discussion on Professor Beresford Pite's paper, "The Aesthetic Treatment of Concrete."

Architects, Society of, 28, Bedford-square, W.C., 8 p.m. Mr. G. C. P. Monson, "Housing."

FRIDAY, FEBRUARY 9...Royal Institution, Albemarle-street, W., 9 p.m. Dr. J. A. Harker, "Very High Temperatures." (With electric furnace experiments.)

Medical Officers of Health, Society of, 1, Upper Montague-street, W.C., 5 p.m. Dr. G. A. Auden, "Open-air Schools."

British Foundrymens' Association (London District), Cannon-street Hotel, E.C., 8 p.m. Mr. J. Edwards, "Brasses."

Municipal and County Engineers, Caxton Hall, Westminster, S.W., 7.30 p.m. Discussion on paper by Mr. W. J. A. Butterfield, "The Relation of Modern Road Surfacing to Fish Life."

Physical, Imperial College of Science, South Kensington, S.W., 5 p.m.

Civil Engineers, 25, Great George-street, S.W., 8 p.m. (Students' Meeting.) Captain H. R. Sankey, "Steam Turbines: Some Practical Applications of Theory." (Lecture II.)

SATURDAY, FEBRUARY 10...Royal Institution, Albemarle-street, W., 3 p.m. Sir Alexander C. Mackenzie, "Franz Liszt (Centenary)." (With musical illustrations.)

NOTICES.

NEXT WEEK.

MONDAY, FEBRUARY 12th, 8 p.m. (Cantor Lecture.) LOUDON M. DOUGLAS, F.R.S.E., "The Meat Industry." (Lecture II.)

WEDNESDAY, FEBRUARY 14th, 8 p.m. (Ordinary Meeting.) CECIL THOMAS, "Gem Engraving." SIR ARTHUR JOHN EVANS, D.Litt., LL.D., F.R.S., will preside.

Further details of the Society's meetings will be found at the end of this number.

CANTOR LECTURE.

On Monday evening, February 5th, MR. LOUDON M. DOUGLAS, F.R.S.E., delivered the first lecture of his course on "The Meat Industry."

The lectures will be published in the *Journal* during the summer recess.

INDIAN SECTION.

Thursday afternoon, February 8th; SIR FREDERIC W. R. FRYER, K.C.S.I., formerly Lieutenant-Governor of Burma, in the chair. A paper on "The North-Eastern Frontier of India" was read by COLONEL SIR THOMAS H. HOLDICH, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc.

The paper and discussion will be published in a subsequent number of the *Journal.*

PROCEEDINGS OF THE SOCIETY.

COLONIAL SECTION.

A meeting of the Colonial Section was held on Tuesday, January 30th, 1912. THE HON. SIR RICHARD SOLOMON, G.C.M.G., K.C.B., K.C.V.O., K.C., High Commissioner for the Union of South Africa, in the chair.

THE CHAIRMAN, in introducing the reader of the paper, said that the subject of irrigation was of very great interest and importance to those who were concerned in the development of the agricultural industry in South Africa. The author was fully competent to deal with that subject, because he was for many years attached as an engineer to the Irrigation Department in the Cape Province, which he knew from beginning to end; he fully appreciated from practical experience the great advantage of irrigation to the cultivators of land in South Africa, and he also appreciated the great difficulties which people who went in for irrigation works in South Africa had to contend with.

The paper read was—

IRRIGATION IN SOUTH AFRICA.

By W. A. LEGG, M.Inst.C.E.

INTRODUCTION.

The new Union of South Africa contains some 473,000 square miles, with a population of about one and a quarter million Europeans and four and three-quarter millions coloured. In the year 1910 there was imported into the country over sea, agricultural produce, including grain, flour and meal, meat, milk, butter and cheese, etc., of the value of over three million pounds sterling.

What is the reason that after 250 years of occupation by Europeans so vast a country is still unable to supply sufficient food for its inhabitants, whose density all told is under thirteen persons per square mile, whilst that of the white people who are, after all, those for whom imports are chiefly made, is under three persons per square mile?

No one cause will fully account for this; it is contributed to by many, and the history of the country affords some explanation of the slow progress made. Of the four colonies included in the Union, the Cape is the only one

Hosted by Google

which, previous to the middle of the nineteenth century, enjoyed for any considerable period the peace so necessary to agricultural development—and that only in the western province. Fighting with the natives upon the eastern and northern borders was in constant progress. Skirmishing with, and driving off, thieving and marauding bands developed occasionally into organised punitive expeditions, and kept the settlers constantly on the *qui vive.*

Internal political difficulties added cause for disquiet, and on more than one occasion threatened serious civil strife. All these things were against the agricultural development of the country, and caused the farmers in the east frequently to abandon lands which they had taken up and partly reclaimed, and to trek to new parts. The history of the occupation of the Orange Free State and the Transvaal is one of a people trekking to avoid dangers and uncongenial surroundings, rather than of a people marching to possess a land of promise, and the wonder is not that so little progress was made, but rather that the early settlers had the courage to persevere against such adverse circumstances.

Hindrances to Progress.

About 1875 troubles with the natives may be said to have ceased, and from that time amongst the causes militating against progress the following were, perhaps, the most potent:—

1. The distribution of the white population, which was so thinly scattered throughout the country as to prevent or render difficult intercourse and mutual action for advance.
2. Adverse climatic conditions.
3. Difficulties of transport.
4. Legal difficulties.

The lack of intercourse with their fellows produced a general apathy amongst a large section of the farming population—the Boers. They lived in a condition of isolation, such as the inhabitants of civilised and closely populated countries can hardly realise, and to the dwellers in the back veld the traditions of their forefathers had become the only rules of life. Here was no new thought, no progress. For generations they had been a pastoral people, undertaking only such cultivation of the ground as was necessary for their own immediate wants, which, indeed, were few. They knew the rainfall to be scanty, and were accustomed to periodic droughts, when even their natural pasturage was burned up, and ceased to afford feed for their flocks, which often perished in large numbers in consequence. The river courses they found through the greater portion of the year as dry as the remainder of the country, and when water did flow it was generally only for a few days at a time; so that if they were able to preserve sufficient water for their stock it seemed as much as could reasonably be hoped for. Thus they remained a pastoral people.

Difficulties of transport were so great that if a farmer was fortunate enough to have water on his farm which might be of use for irrigation, unless he was within reasonable distance of a railway, he was generally faced with an almost impossible task in getting to a suitable market any crops which he might produce. It must be remembered that the railways are of comparatively recent origin. Of the 6,000 odd miles now open, there existed in 1875 only a few short lines from the coast, not exceeding about 150 miles in all.

The trunk lines of the country have been constructed for the exploiting of its mineral wealth, and only in consequence of that wealth have they now traversed so great an extent. Of later years branch lines have been built, and greater facilities extended to the agricultural population, but there is still much to be done in order to open up the country. There appears to be an opportunity to apply motor vehicles, running upon the roads, to feed the railways, and such a system, if initiated, might do much to encourage agricultural activity. The whole population is small, and large centres, where alone considerable markets for farm produce exist, are generally far removed from the best lands; also, in many cases transport by sea will bring food at much cheaper rates than it could be delivered at by the railways from the interior, so that clearly the farmer is not much encouraged to supply these markets until some better transport facilities exist.

The last cause which was named against development of irrigation was legal difficulties. The state of the law was not by any means calculated to promote the practice where the possibility existed, and attempts at irrigation were productive of much litigation, which could not but discourage its extension.

With all these adverse conditions it is not very surprising that the country remained almost entirely a pastoral one, though even in that capacity it left much to be desired. The natural veld, which provides practically the whole of the pasturage, may at its best carry one sheep to three or four acres, but owing to climatic conditions it very seldom is at its best, and

Hosted by Google

the number of sheep which it will carry varies from the figure given to zero.

In the early days of the white occupation there were large areas of country unoccupied, and farmers were in the habit, when their own veld became poor, of trekking away with their flocks to fresh pastures, and of returning to their own when it had become refreshed by rain and rest. As, however, land became more taken up it became increasingly difficult to find fresh veld, and hence in times of drought flocks must either be fed artificially or perish. There is no doubt also that when first occupied by Europeans much of the country—practically all the valley bottoms—was in much better condition of pasture than it is to-day. The present deep-river channels did not exist, and the valleys were rich vlei land covered with luxuriant vegetation. This change which has taken place will be referred to again later; it has been very harmful to the country, and must have reduced its stock-carrying capacity enormously. The recognition of these facts serves to indicate one direction, at any rate, in which irrigation may for a long time to come be very profitably directed—viz., to improving the natural pasturage, restoring the valleys to their earlier vlei condition, and growing forage crops for flocks and herds. This would not only provide against the dangers of drought, but would tend to increase the stock-carrying capacity of the country. It would also at once remove that most powerful deterrent to crop production—viz., the difficulty of transport, for crops fed to cattle can very readily be transported to market.

Crops without Irrigation.

The growing of crops on the rainfall alone, without artificial watering, can only be attempted in some of the more favoured portions of the country, and these collectively do not form a large proportion of the whole.

The simplest crops, and those which would naturally be first tried by a pioneer farmer, would be the commoner cereals—wheat, oats, and barley. These crops do not require a large amount of water, but are rather particular as to when they receive it. A good wetting of the land is necessary before ploughing can be accomplished, and again during the growing period at least one good watering is required.

Wheat is generally sown some time between May and August, and that and its growing time are the dry season over most of the country; therefore it is generally imperative that the soil should have been thoroughly wetted before sowing. If that has not happened it is useless to sow, and as it rarely happens in South Africa —except in special localities—so the growing of cereals on the rainfall is rare also.

The south-western portion of the Cape Colony, and what is known as the conquered territory in the Orange River Colony, are almost the only large areas where wheat-growing on the rainfall is carried on. The former is particularly favoured by nature for the purpose, as it has a good rainfall averaging 18 ins. to 20 ins. per annum, and receives the greater portion of it during the sowing and growing season of wheat.

An area of some 7,000 square miles lying around Malmesbury, produces annually quite half of all the wheat grown in the Cape Colony. In 1904 this district produced about 850,000 bushels out of a total of 1,685,000 bushels grown. These figures are taken from the census returns of 1904, and are the last reliable figures published. The Orange River Colony is able to produce wheat on the rainfall along the valley of the Caledon River, but the Transvaal grows practically none. Besides wheat, mealies are almost the only other crop grown on the rainfall. They are produced in the Transvaal, Orange River Colony, and Natal, in quantities increasing yearly, and are a summer crop requiring most moisture in December, January, and February, a condition which exactly suits the climate. There are those who expect to see the export of mealies develop into a large trade. On the European market, however, there are many competitors who will assist in keeping the profits at a low figure.

Another area which has for long produced wheat of excellent quality, and in quantity increasing year by year, is the valley of the Zak River in the north-west of the Cape Colony, but there it is not grown on the rainfall, which is extremely scanty, but on a system of flood-irrigation to which further reference will be made later.

Outside of the favoured areas referred to, it has not yet been found practicable to produce, with any certainty, crops on the rainfall only. That this will be materially altered in the near future is very probable. Experiments in dry farming are in progress, undertaken by both the State and individual farmers, which go to show that very successful results may be accomplished, and lands which have hitherto been classed as arid and unproductive, will doubtless be made to yield crops of cereals, grasses, and even lucerne. The further discussion of this subject, however, deeply interesting though it is, is outside the scope of this paper.

Rainfall.

It may at this stage be useful to remark briefly on the rainfall of the country, as it has a very important bearing on irrigation, and the possibilities of its development.

The rainfall varies from $2\frac{1}{2}$ ins. per annum, or less, in the north-west of the Cape Colony, to between 40 ins. and 50 ins. on the coastal regions of Natal, with still heavier precipitation at a few local centres, notably in the south-west of the Cape Colony, where, upon a small area extending from Cape Town to Ceres, rainfalls up to 80 ins. per annum are registered in the mountains.

Very heavy rainfalls are also experienced in the mountains of Natal. Over the whole country the rainfall is generally least on the western side, and increases steadily towards the east.

In the Transvaal, the Orange River Colony, and the north and east of the Cape Colony, the rain falls chiefly in the summer months, and only the south-west of the Cape Colony is subject to winter rains.

Along the south coast the rain is fairly evenly distributed throughout the year. A meteorological commission has existed for many years in the Cape Colony, and has collected a very valuable record of rainfall from some 450 stations distributed over the whole country.

In the other States, records have not been kept so systematically, but during recent years steps have been taken to correct this, and the Transvaal has now a greater number of gauges in proportion to its area than the other States, and will probably before long have actually a greater number than any other State. The Orange River Colony has also moved in the same direction during the past few years. The records show that in most parts of the country the rainfall is generally fairly regular. It must be noted, however, that occasional extremes both of wet and drought are experienced. Looking through the records for the decade 1898–1908, rainfalls of from 3 ins. to $4\frac{1}{2}$ ins. in twenty-four hours are found at places scattered throughout the length and breadth of the Karoo and Orange River Colony. In the Transvaal, falls of from 5 ins. to $11\frac{1}{2}$ ins. in twenty-four hours are recorded in most districts to the east of 28° Greenwich longitude; whilst along the south coast districts falls varying from 5 ins. to $16\frac{1}{2}$ ins. in twenty-four hours have been measured.

On the other extreme, we have many instances throughout the Karoo of total rainfall for twelve months amounting to less than 4 ins., and there are several gauges which have received absolutely no rain for a period of twelve months.

A knowledge of this possibility of extremes is of immense importance to the engineer designing irrigation works. The possibility of droughts, warns him of the necessity to provide storage, and the possibility of floods, of the necessity to make sufficient provision of spillways to insure the safety of his works.

The mean annual rainfall of the Cape Colony is about 15 ins., that of the Transvaal about 29 ins., of the Orange River Colony 21 ins., and of Natal about 34 ins. The mean for the whole of the Union is probably about 20 ins. per annum.

The heaviest rains occur in the mountain districts and on the eastern side of the country, and it is safe to say that there is very little of the best soil of the Karoo which receives sufficient rain to remove it from the unenviable category of arid lands, or to offer much inducement to attempt cultivation on the rainfall only.

Moreover, small as the rainfall is, and although the greater portion of it falls in the wet season—which is the summer—it is generally distributed throughout the whole year, so that in a year of small total rainfall, individual rains are usually so small as to be of little or no service. As an illustration of Karoo rainfall, the following figures, based upon twenty-eight years' records taken at Hanover, may be of interest. Observations have been made for over thirty years, but unfortunately those for the two years 1892–3, are incomplete, so have been omitted from the analysis.

The table gives for each month the mean total rainfall, the number of days on which rain fell, and the average amount for each of those days.

Month.	Mean Total Rain for Month in inches.	Number of Rain Days.	Average Fall per Rain Day in inches.
January	1·72	5	·34
February	2·04	6	·34
March	2·38	6·1	·39
April	1·56	4·5	·35
May	1·11	3·5	·32
June	·50	2	·25
July	·43	1·5	·29
August	·36	1·3	·27
September	·72	2·5	·29
October	·83	3	·28
November	·92	3	·31
December	1·18	3·6	·33
Totals for year	13·75	42	·32

Hosted by Google

The mean total annual rainfall is 13·75 ins. It will be seen that the wet and dry seasons are well marked. Dividing the year into two periods of six months each, we find that about 75 per cent. of the total rain falls in the period including the months December to May, and only 25 per cent. in the other six months. We see that the wettest month is March, with a mean of 2·38 ins. This is not a heavy month's rainfall, and its distribution decreases its possible utility. Thus the average number of days in March on which rain fell is 6·1, so that the average amount which fell on each rain day was only ·39 in. These remarks apply *mutatis mutandis* to the other months of the rainy season, and the figures for mean rainfall per day on which rain fell are remarkable for their regularity. During the six wet months they vary only from ·32 in. to ·39 in., and during the dry season from ·25 in. to ·31 in. per day, the average for the year being ·32 in.

The years of minimum and maximum rainfall, *viz.*, 1903 with 1·74 ins., and 1891 with 25·75 ins., are both remarkable, the former having only 13 per cent. and the latter almost double of the mean. During the minimum year the average rainfall on the days on which rain fell was ·08 in., and the maximum fall on any day was ·40 in., whilst during the maximum year the figures were ·41 in. and 2·95 ins. respectively. The fact of the wet season being in the summer is against the growing of cereals, which are usually sown from May to August, and though suited to the maize season the rainfall is hardly sufficient for the production of that crop. The rainfall at Malmesbury is not so very different from that of Hanover in quantity, but the bulk of it falls during the growing season of cereals. Thus, whilst Malmesbury, out of a mean total annual rainfall of 18·23 ins., receives nearly 14 ins. during the six months April to September, Hanover has only 4·68 ins. during the same period out of its total of 13·75 ins. During the driest year on record, Malmesbury received during the six months named, 7·28 ins., whilst Hanover had only ·62 in. in its driest year.

Run-off.

Very little reliable information is as yet available regarding the proportion of run-off to rainfall. It is one of the questions engaging the attention of the Irrigation Department. There is no doubt that the percentage has a wide range throughout the country, attaining a maximum on the mountains which lie within zones of high rainfall, and a minimum on the plains within zones of low rainfall. The run-off from any area will vary for different times and seasons, being generally highest in the rainy season and lowest in the dry. It will be influenced by many factors, *e.g.*, the amount and intensity of rainfall, the temperature, condition of the ground immediately preceding rain, etc. Of any single factor the *amount* of rain will probably have the greatest influence, and the amount combined with intensity will always show a dominating influence.

It is extremely difficult to obtain reliable run-off results, for even small catchment areas, chiefly owing to the difficulty of obtaining an accurate mean rainfall on the area, and on large catchments the possible local variations render it more difficult still. The Cape Colony is the only State of the Union where observations have been continued long enough to permit even rough approximations to be made, and the author is of opinion that 5 per cent. of the rainfall may safely be assumed to flow off as a mean for the whole Colony. Such results as have been obtained in the Transvaal go to show that, at any rate for the area draining to the Atlantic Ocean, a smaller result would have to be assumed, and the same would probably apply to the Orange River Colony. The heavier run-off from the mountain districts benefits the country by providing water for irrigation. Attempts have been made to estimate the quantity of water flowing annually to the sea, and though the results must of necessity be only approximate, they form some basis on which to estimate the possibility of irrigation. While the proportion of water utilised is only a small fraction of the total quantity, the figures are useful, and should the time come when a large proportion is being utilised, it will be necessary to revise the estimate, and no doubt by that time the data available will simplify the task.

The author has estimated that in the Cape Colony the total mean annual amount of water precipitated as rain over the whole surface is about 218,000,000 acre feet, and that at least 5 per cent. of this flows off to the sea. Assuming that four acre feet per annum flowing in the river channels would irrigate one acre, which is a liberal allowance, we find that there is sufficient water flowing to waste for the irrigation of about 2,700,000 acres. Although it is not known at present what area of irrigable land is in the Colony, a general knowledge of the country gives one confidence in saying that there is certainly not less than the above-named area which would be well worth irrigating, so that there is every probability that a good use could be found for all the available water. The last census return of 1904 gives the total area irrigated in the Cape

Hosted by Google

Colony as about 400,000 acres. During the past few years considerable activity has been shown, and probably 100,000 acres additional might now be estimated as irrigated, or likely to be so in the near future, so that we may assume at least 500,000 acres now under irrigation. This would leave at least two million acres in the Cape Colony which it is possible might be brought under water. Good land under irrigation could hardly be worth less than £10 per acre, whilst the best might be worth £100, so that here is seen a prospective increase of wealth to the country well worth some pains to procure. Of the other States of the Union, sufficient data are not yet available to enable estimates to be made. In the Transvaal there is said to be about 100,000 acres now under irrigation, chiefly from perennial streams.

There is plenty of scope for irrigation extension in both the Transvaal and Orange Free State, but the problem is somewhat different from that in the Cape Colony. To begin with, there is a better rainfall, and when the rivers are in flood the riparian lands have generally benefited by the rain, which raised the rivers, and so do not require further irrigation. That characteristic of the Karoo, viz., of the rivers coming down in flood with little or no rain upon the irrigable lands, does not apply. Therefore, in the northern States storage will be more generally necessary as part of any irrigation scheme not on perennial water.

Law Relating to Irrigation.

It may be well now to consider briefly the remaining condition which has in the past influenced greatly irrigation development—viz., the law governing the rights to, and use of, water. We shall then look generally at what has been done in the way of irrigation in the past, and at what are the possibilities of the future. In a country where water is scarce and valuable, the law regarding its ownership and use must of necessity exert a great influence upon the extent to which irrigation will be practised. In the early days of the country's history, water disputes were heard by boards of Landdrost, but in 1827 these were abolished, and such cases were afterwards heard by the Supreme and Circuit Courts. There was no statute law on the subject. From 1861 onward, several attempts were made by the Parliaments of the Cape Colony to legislate on this subject, but it was not until 1876 that any result was achieved. In that year an Act was passed, entitled the Right of Passage of Water Act, to enable persons having right to water to convey it across the land of other persons, but the Act proved of little practical use.

In 1877 the first Irrigation Act was passed, which made provision for the establishment of irrigation boards and districts, and for grants of Government loans to such boards or to private individuals for the construction of irrigation works. The price charged for such loans was 8 per cent.; 6 per cent. as interest, and 2 per cent. for amortisation to extinguish the debt in twenty-four years. In 1879 the Act was amended to allow municipalities also to borrow money for irrigation works under the same conditions.

In 1880 the Act was further amended to allow of the advance of one-fifth of the total amount of a loan before the commencement of the works, instead of allowing payments only on the value of work executed. The new Act also provided for the redemption of the loan in a less period at the option of the borrower, with the consent of the Minister of Public Works, the sinking fund varying according to the period. The municipalities appear to have been the only persons to make use of these Acts so far as borrowing was concerned.

In 1893 a short Act was passed allowing private individuals to borrow on the same terms as boards. In 1897 an Act was passed reducing the rate of interest charged on loans to 3½ per cent. plus an amortisation payment necessary to extinguish the debt in such number of years as the Minister might approve, not exceeding forty.

In 1899 was passed the Water Act, which provided for the appointment of Water Courts for hearing disputes connected with the use or appropriation of water, for hearing applications from riparian owners entitled to divert water from public streams for permission to take it at some point upon the land of another owner, to apportion the flow of a perennial stream between several owners on the application of one or more of them, and to prescribe the mode of such division. The Water Court could deal only with cases where there was not already any registered prescriptive rights, and its judgment was subject to appeal to the Supreme Court in case any person affected was dissatisfied.

Water Courts under this Act were established only as the necessity arose—*i.e.*, when some owner desired to bring a case up. There was always the Supreme Court, and the case could only go to the Water Court by consent of all parties. Very few Water Courts were actually established under the Act, but such as were appear to have acted very satisfactorily.

Hosted by Google

The statute at present in force is the Irrigation Act of 1906, based upon the earlier Acts, all of which it repealed. This Act gives original jurisdiction to the Water Courts in cases of water disputes which can only be first heard in the Supreme Court by consent of all parties (in this respect it is the exact converse of the Act of 1899), except in cases where the disputes arise regarding rights obtained by the judgment of a superior court, the award of an arbitrator, or as a condition of grant or transfer.

Besides retaining the Water Courts of the earlier Acts with increased powers, and the Irrigation Boards, provision is made for the constitution of river boards and districts.

The river board is to exercise a general supervision over streams in its district, with power to cleanse, widen and otherwise improve them; to prevent unlawful diversion of water, to record the flow of the streams, prepare maps of the district, collect hydrographic data, and generally to take steps to increase the utility and use of the water in the district. The Board may supervise the distribution of water according to established rights, but has no power to create rights; and it may levy rates—called river rates—to defray expenses incurred. Appeals against acts or orders of the river board may be made to a Water Court or other competent court. An irrigation board is usually appointed for the purpose of constructing and managing a specific scheme of irrigation in the interest of two or more owners of property co-operating in a joint work. Thus there might be several irrigation boards within one river district, and several river boards within one Water Court district. Both river and irrigation boards are elected by the owners of property in the districts from amongst their number, but the Water Courts are composed of a resident magistrate having jurisdiction in the district (who will act as chairman), and two assessors selected from a list of Water Court assessors approved by the Governor after consultation with the divisional council of the district. Such assessors must be owners and occupiers of land in the district. The selection of the two assessors to hear any particular case is by lot. Any of the parties to the case may object to an assessor on certain grounds named in the regulations, and the magistrate shall decide whether or not the objection shall be allowed. If allowed, a new drawing of names takes place.

The Irrigation Act of 1906 introduces some considerable alterations into the law relating to water rights as it previously stood. It legislates for intermittent streams, as well as for perennial ones. This was, indeed, one of the chief objects of the Act. It takes away the absolute ownership in an intermittent stream from the person on whose land it flows, which, under the common law, he enjoyed, and prevents him from leading away the water of such stream for use on non-riparian lands, except by permit from the Water Court, which permit, however, shall apply only to surplus water. It also allows prescriptive rights in the water to a lower owner on to whose land some of the water has flowed for a period of thirty years, which right he could not previously claim under the common law. The Act further makes provision for the diversion of the surplus water of a perennial stream across a watershed. Thus, whilst curtailing to some extent the use of the intermittent stream, the Act extends the use of the perennial water. It gives to the Government, and to some extent to river and irrigation boards, the power to expropriate land for irrigation purposes on payment of compensation to the owners, allows boards and individuals to claim servitudes or easements on the land of others, and makes provision for the granting of Government loans to boards or individuals for irrigation purposes.

In 1908 regulations were proclaimed under the Act, which have equal force with the Act itself. Under the Irrigation Act of 1906, Water Courts have been established over the whole of the Cape Colony, which for the purpose has been divided into sixty-five districts, the boundaries of which correspond more or less with those of the fiscal districts.

In 1908 an Irrigation Act was passed in the Transvaal, framed on the lines of that of the Cape Colony, and no doubt it will be an early care of Parliament to prepare a uniform Act for the whole Union.

Natural Herbage.

The surface of the country included in the Union lies generally at a high altitude, almost the whole of the cultivated lands, with the exception of a strip along the coast, lying at from 2,000 ft. to 6,500 ft. above sea-level.

In the Cape Colony the natural herbage of the veld consists of varieties of short bush—many of them aromatic—which provide excellent pasture for sheep, goats, cattle and ostriches; excellent, that is to say, as to quality, though its quantity, owing to lack of moisture, is often less than desirable. In the Orange River Colony and the Transvaal the veld is generally covered with grasses, some of which afford good pasture, while others are more or less poisonous.

Hosted by Google

A good deal is now being done in all parts of the country in the way of introducing better classes of grass, and the experiment promises good results.

Early Irrigation.

As might be expected, the earliest efforts at irrigation were with the waters of perennial streams, where the water could be utilised by means of a simple weir to turn it out of the stream channel and a canal or furrow to convey it to the land. Such method has been practised in parts of the country for many years, and there is still to be seen a furrow leading from the Breede River in the Cape Colony which is said to have been constructed over eighty years ago. The Oudtshoorn district has always taken the lead in this class of irrigation, being favoured with a perennial stream flowing through very fertile lands, which have been worked to great advantage. This district has for many years led the way in ostrich farming, in which lucerne cultivation under irrigation has been a prominent feature, but of late years this has also been taken up in a spirited way in the eastern province, and is now extending gradually throughout the whole country. The growth of this important industry is shown by the following figures:—

In 1865	there	were	about	80	tame ostriches in the country.
,, 1875	,,	,,	,,	21,750	,, ,,
,, 1891	,,	,,	,,	154,880	,, ,,
,, 1904	,,	,,	,,	357,970	,, ,,
,, 1910	,,	,,	,,	500,000	,, ,,

In 1908 nearly 800,000 lbs. weight of feathers were shipped from Cape ports, valued at over £2,000,000. Ostrich farming has long been a most remunerative industry, and its development has done much to promote irrigation, particularly by fostering and increasing the growing of lucerne. It is not to be expected, however, that the rapid expansion shown by the figures given above can continue, and we shall probably see a marked change during the next few years. Fortunately, the capital laid out in lucerne lands will not be lost, for when the time comes that the feather industry cannot profitably be extended, the fattening of cattle upon the lucerne will offer a most valuable field only second to that of ostrich farming. The danger to be avoided is that of capitalising the land on the too high returns obtained from the ostrich industry, which might handicap any less profitable one.

In addition to lucerne, tobacco, fruits, and vegetables have been cultivated under perennial irrigation.

The early irrigation which developed along the perennial streams was entirely due to individual effort, and, as already stated, has been abundantly attended and doubtless much retarded, by litigation. Flood irrigation with the waters of intermittent streams has also been practised for years to a limited extent, chiefly for the improvement of the veld. Many of the intermittent streams of the country, certainly the most important of them which traverse the Karoo, have very deep channels, often 30 ft. and more below the surface of the adjoining land, which renders irrigation from them somewhat difficult. In the early days of the white occupation these channels in all probability did not exist, and rain falling on the land spread itself over the surface of the plains, where it was to a great extent absorbed by the soil, very little water flowing away to the sea. As a consequence the plains were generally in great part vlei, covered with luxuriant vegetation, which provided food and cover for all manner of game. Within recent times this condition has changed. River channels have formed, cutting through the deep alluvial soil down to the bed-rock, by which the rain-water flows quickly away to the sea, carrying with it the easily denuded fertile silt of which the plains are formed, whilst in times of drought the channels tend to drain away all subsoil water and reduce the land to a parched and desert condition. This change has been brought about partly by the tramping of stock too thickly herded together first forming a course for the water, which afterwards developed into a deep channel. The burning of the vegetation, and the construction of roads and railways have also no doubt contributed to the result, the former by producing a more rapid discharge of the rain, and the latter by collecting the discharge and forcing it to follow defined channels. To restore the land to its former condition and prevent the sluiting of the soil and consequent rapid discharge of rain to the sea, would mean untold wealth to the country; and although this would take time, and necessitate considerable expenditure, yet it is not beyond the scope of practical politics.

In spite of the difficulties offered by the deep-river channels, where conditions were favourable for turning out the water upon fertile lands, advantage has been taken by the more enterprising farmers to improve the veld by flood irrigation, and at times to utilise the water for the cultivation of lucerne and other crops.

The early irrigation works were generally constructed in a simple manner. Weirs were of

Hosted by Google

masonry, concrete, or stone and wire, according to local conditions. The last named is simple and, when well built, effective. It consists of stone, usually boulders collected in or about the river-bed, built into the required form and enclosed within a wire netting, which prevents the displacement of the stones. Sometimes the wire netting is made first and laid down on the river-bed. The dry-stone weir is then built upon it, and the loose edges of the net drawn over the top and fastened together, thus completely enclosing the stonework. Another method of building this form of weir is to lay down on the river-bed single wires, representing the warp of the net, and to work in the weft, and enclose the stonework as it is built up. The former method gives generally neater work, but perhaps costs rather more than the latter. The wire used is strong galvanised fencing wire. Such weirs are very effective to heights of 5 ft. or 6 ft., particularly on rivers which carry much silt, the silt quickly filling the interstices of the stones and rendering the work watertight.

Zaai Dam Irrigation.

An interesting method of flood irrigation, already casually referred to, is practised in the north-west of the Cape Colony, particularly along the valley of the Zak River. It is called "Zaai dam irrigation," and has been compared to the Basin method of irrigation in the Nile Valley, on a small scale. The Zak and Fish Rivers take their rise in the Nieuwveld mountains to the west of Beaufort West, and drain a very large extent of country. Above Kenhardt the catchment area is about 17,500 square miles, and above Brand Vlei about 15,000 square miles. At one time the Zak River must have been nothing but a succession of vleis for at least 100 miles of its course, where all the rainfall, except the largest floods, was retained. Now, however, there is a channel 15 ft. to 20 ft. deep, and up to 100 ft. or so wide, cut through the fine, rich alluvial deposit. For the greater portion of the year the channel is absolutely dry, and it has so drained the riparian lands that they are now arid and desert. The river usually flows once or twice during the summer season, sometimes oftener, owing to rains upon the upper portion of the catchment area, but in consequence of the rapid discharge effected by the deep channel, flow ceases almost as soon as the rain stops, so that the aggregate of flow for the year will generally not exceed a few days. And so deep is the channel now below the surface that it is only in exceptionally heavy floods that the river overspills its banks naturally, and wets the land. In order to bring this about more readily, and with smaller floods, weirs, usually made of earth and of quite a temporary nature, are thrown across the channel, which raise the water over the banks, whence it spreads over the land. The spreading of the water is aided by the rather curious circumstance that the land often falls away from the river banks, as shown in Fig. 1, which is a cross-section at right angles to the river channel. This condition

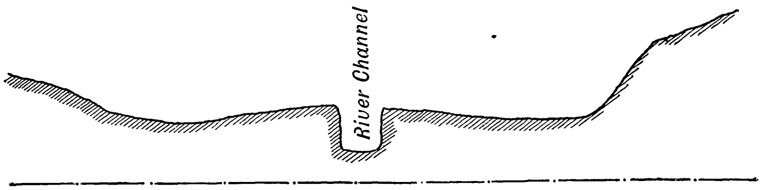

Fig. 1.

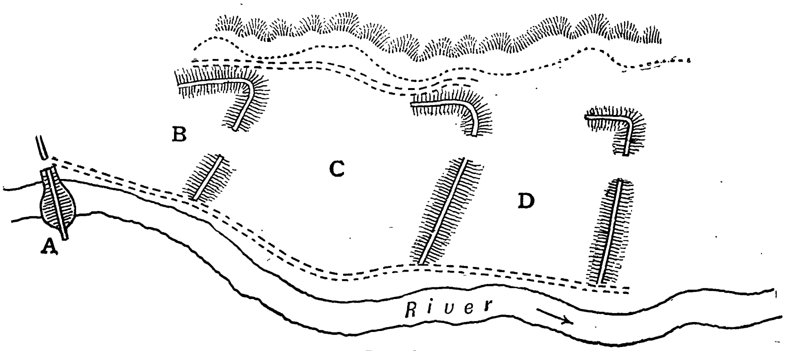

Fig. 2.

Hosted by Google

is brought about by the fact that the river more often floods the land near to its banks than that more remote, and as each flooding means a deposit of silt, with which the water is always fully laden, the lands adjacent to the river oftener receive deposits, and so gradually rise to the higher level.

The water, having been turned out of the river channel by the weir, is held on the land by low earth embankments of a few feet in height, arranged as shown in sketch (Fig. 2). A shows the temporary weir across the river; B, C and D are Zaai dams, which may be flooded by passing the water down from one to another by means of temporary gaps cut in the embankments, or they may be fed by a furrow cut either along the river bank or at the foot of the koppies which bound the valley, as shown in dotted lines in the sketch; or the dams may be so made that the water is thrown over against the foot of the koppies and flows between them and the ends of dams remote from the river, filling each dam in turn without any furrow. Whichever way they are filled, the water is held in the dams as long as is considered necessary in order to soak the ground thoroughly, or if the water comes rather early in the season it may be held until sowing time approaches. The water remaining is then allowed to drain away, and the area which was submerged is ploughed and sown with wheat, which will mature and yield a good crop without further watering.

The weir A may be destroyed each season, but the Zaai dams would probably serve for a good many seasons. These dams are usually made with scrapers drawn by oxen, which give very cheap work. Owing to the flatness of the land a small amount of earthwork will generally serve to flood extensive areas, and a single Zaai dam may be of any size, from two or three acres up to a square mile or more. Although this method is as yet confined almost entirely to the Zak River, it is being copied in other parts, and there are many districts where it, or some modification, could be followed with advantage.

Sowing usually takes place between May and August, and reaping about the end of November or early in December, but crops are sometimes sown as late as December. Thirty-fold is considered a fair average crop, though higher returns are often got, particularly if a second watering should be obtainable. The seed is sown rather thinly (about 25 to 30 lbs. per acre), owing to the richness of the soil and consequent stooling of the plants. The writer has counted over eighty stalks on one root. Thirty-fold would therefore mean about 3½ to 4 bags per acre reaped.

Boreholes.

Added to these methods of irrigation was that from boreholes and wells. From about 1884 until 1908 the Government of the Cape Colony did a large amount of boring for water in the north-western districts of the Colony and Bechuanaland, assisting farmers financially on the pound for pound principle. During that period the Government's share of expenditure amounted to about £450,000, as a result of which some 5,600 boreholes were put down, which, in the aggregate, yielded about 18½ million gallons per day of flowing water, in addition to an estimated 35½ million gallons available by pumping, or a total of 54 million gallons per day. Although the work cannot be said to have been done cheaply, it has been of immense value to the country, particularly to stock-farmers. The boreholes are mostly rather shallow. The average depth of the whole 5,600 would probably be under 100 ft. each. In addition to the boreholes put down by the Government there were many others done entirely by private enterprise, so that there are probably not less than between 8,000 and 9,000 now in existence throughout the Cape Colony. Where pumping is necessary it is usually done by windmills, though some oil-engines are also used.

In 1904, boring operations were also commenced in the Transvaal, and the Government has now transferred its attention almost entirely to that State.

In 1908 the Government subsidy was discontinued in the Cape Colony, the necessity for it having, to a great extent, disappeared, owing to the work of boring having been taken up by private firms at cheaper rates.

The majority of the boreholes were not put down for the purpose of irrigation, but primarily for the watering of stock; nevertheless, a good deal of the water over and above that used for the latter purpose is applied to irrigation, chiefly to patches of a few acres in extent in the neighbourhood of the homesteads.

Small reservoirs with earthen dams—known as farmers' dams—are numerous throughout the country. Most of them have been constructed to provide water for cattle, but many contribute also for irrigation on a small scale. They are usually built in hollow places, where the drainage from small catchments can be caught in times of rain, and generally avoid stream courses from large catchments. The dams seldom exceed 10 to 12 feet at the highest part.

Hosted by Google

The following figures give some idea of the progress of irrigation during the fifteen years preceding the passing of the Irrigation Act of 1906.

	Area Irrigated, in Acres.	
	In 1891.	In 1906.
From small dams, wells, boreholes, etc.	48,000	50,000
From perennial streams .	192,000	230,000
From intermittent streams	69,000	140,000
Total area . . .	309,000	420,000

RECENT IRRIGATION DEVELOPMENT.

Since the passing of the Irrigation Act, there has been considerable activity, and there is probably now at least 500,000 acres under irrigation in the Cape Colony alone. No doubt this is partly due to the improved conditions under the new law, but it is probably quite as much due to the more sympathetic attitude of the Government and the beneficial influence of the Irrigation Department. This department is now emancipated from the Public Works Department, of which it once formed a branch, and is freer to take a more practical and businesslike interest in the development of irrigation than it was in the past.

It has afforded much assistance to farmers, through its technical officers advising as to engineering details of schemes and as to financial results to be expected.

A good many works have been carried out in this way, varying in size from the small scheme to irrigate 20 or 30 acres to the more ambitious one dealing with several thousand acres. One of the largest, if not the largest, works of the kind in the country is now being constructed by the Smartt Syndicate on their farms in the Britstown district. The works will include a storage reservoir on the Ongers River, with a capacity of over 3,000 million cubic feet.

The dam will be the highest earthen dam in the country (about 60 ft. above the river-bed), and is made entirely of the silty alluvial earth of the district. The greatest care has been taken in the making of the dam, and much interest attaches to the result of constructing so high a dam with this class of earth.

For storage dams the earthen embankment is almost the only structure employed. Masonry or concrete dams have been built in several places, but always either for domestic supply only, or for that and irrigation combined, where the irrigation has been looked to to assist the municipal revenue. So far as the writer is aware, the only masonry dam in the country built entirely for irrigation purposes is on a settlement scheme in the Orange River Colony being carried out by the Government. Unless a site is very greatly favoured by nature, the masonry dam must prove too expensive for irrigation.

The earth generally used for the construction of earthen dams is not such as would appeal to European engineers for the purpose. There is little real clay in the country, and the alluvial ground used is usually light silty loam. For low dams it has, with careful construction, answered well, but its suitability for high dams has yet to be proved. In the smaller dams it is not usual to introduce puddle cores; indeed, suitable material would not often be available, and the best that can be done is to select the best of the material for the centre portion or the water side of the dam.

Reinforced concrete has been used in the construction of aqueducts and siphons. Imported materials of construction such as cement, ironwork, etc., are usually expensive up country, owing to cost of transport, but otherwise prices for work are not much in excess of European prices. Native labour is employed for all except skilled work, the rate of pay being from 2*s.* to 3*s.* per day.

The Government has, under the Act of 1906, advanced a considerable amount in loans for the construction of works. One of the most interesting features in the working of the Act is the number of irrigation boards which have come into existence and taken advantage of the Government loan system. Previous to the passing of the Act there were only three such boards, all of them in the Breede River valley, and working with perennial water. Two of these may be said to have been formed whilst the Act was under consideration, though the other had existed since 1904. Between 1906 and 1910 seven other boards were established, and all have works now in course of construction under Government loans, which will irrigate in the aggregate about 24,000 acres, at a cost of £110,000. The whole twelve districts in existence at the end of 1910 will include some 37,000 acres of land rated for irrigation, with works estimated to cost about £165,000. Several other large schemes involving the

Hosted by Google

formation of irrigation districts have been investigated, some at least of which will fructify.

Only those who know how mutually suspicious of one another the farmers have been in the past, particularly where questions of water-rights were concerned, can appreciate the great advance achieved by the formation of these irrigation districts, necessitating the placing of individual interests under the control of boards for mutual benefit. Again, those who know the farmer will recognise how much greater influence one successful example will have with them than much precept, and will understand the beneficial influence which a dozen such schemes carried out successfully in different parts of the country may have. They will understand also the necessity that such schemes should be successful.

In order to ensure success, so far as possible the Government provides, at nominal charge, the services of the professional staff of the Irrigation Department to make preliminary investigations, and, if the conditions are favourable, to design and advise as to construction of the necessary works, but does not undertake the construction of the works, which is done directly by the boards, who employ contractors or work administratively under the advice of the Department.

These schemes usually consist of a weir and furrow, with occasional siphon or aqueduct to carry the water across valleys or river courses, and the usual regulators, spillways and other incidental works. The largest of the irrigation board works yet carried out is the Breede River at Robertson, which includes an area of 5,576 acres of rated land. The smallest is Vekeerde Vlei, with only 500 acres. The amount per acre which may profitably be expended upon irrigation works will of course depend greatly on the quality of the land, the crops proposed to be grown, facilities for transport, and other conditions. Five to ten pounds per acre in capital expenditure are ordinary figures for South Africa. Few works have cost less than £5, and some have cost considerably more than £10. A higher expenditure would generally be justifiable where permanent water was available than where it was intermittent.

Under the fostering care of the Irrigation Department, the method of irrigation by pumping has been largely extended and generally with very encouraging results. As already remarked, many of the rivers of the country flow in very deep channels, and often with very slight fall, so that to lead the water out by gravitation may be impracticable in connection with schemes dealing with comparatively small areas of ground. For example, the Orange River, over 400 miles of its course, from Aliwal North to Prieska, has an average fall of only 3½ feet per mile, whilst for the lowest stretch of 70 to 80 miles it has less than 1½ feet per mile. The Vaal, from Vereeniging to its junction with the Orange, a distance of some 520 miles, has an average fall of only about 2½ feet per mile. These are probably examples of two of the flattest slopes. The Breede River, from Worcester to Swellendam, which length includes the best lands on the river, has a general slope of about 4½ feet per mile. The Great Fish River, for 100 miles below Fish River Station, falls about 11 feet per mile, and 5 to 10 feet per mile is probably a common slope for Karoo streams.

Irrigation by Pumping.

It is evident that with such slopes, coupled with very deep river channels, it would generally be necessary to carry a canal a good many miles in order to gain command of the land, and such canal would probably extend beyond the upper boundary of the property on which the land to be irrigated was situated.

It is much simpler, therefore, in many cases, if a pumping plant can be put down immediately adjoining the irrigable land, as by that means the capital outlay required may be much reduced and complications with adjoining proprietors avoided.

During the three years ending December, 1909, the Irrigation Department advised on sixty-three pumping schemes of this nature, which in the aggregate cost about £41,000, and irrigate some 6,000 acres. About £20,000 of the total cost was loaned by the Government. Of these sixty-three installations, fifty were suction gas-power plants, which have generally given much satisfaction and in many cases replaced oil or steam engines with advantage.

In addition to these works it is known that a good many others of a similiar nature have been carried out without Government aid. Of pumping plants driven by oil engines about 140 are known to the Department, and there are probably others, so that irrigation by pumping has now become a feature in the development of the country, and its adoption is likely to increase in the future.

It need hardly be said that the average pumping scheme, although it may cost less per acre in capital outlay, will, when working expenses are

Hosted by Google

included, generally cost more per acre per annum than a favourable gravitation scheme. Hence a pumping plant would not be put down where a gravitation scheme could be readily carried out, but many cases occur where, irrigation by gravitation not being practicable, it will be well worth while to water a few hundred acres by pumping. In a pumping scheme there is the great advantage that, the water being generally delivered on the ground by a pipe, there is less loss than with a long furrow, so that a much higher duty is obtained for the water.

The cost of pumping water will obviously vary considerably with local conditions. Near the coast, where overland transport charges are not high, the cost per acre per annum of placing two feet of water on the land would probably vary from £1 to £2 for a 50-foot lift, to £1 10*s.* to £2 10*s.* for a 150-foot lift, including 10 per cent. depreciation on capital. Up country these figures might be increased to £2 10*s.* and £3 respectively.

Financial Results.

Whatever arguments may be advanced in support of irrigation, it must finally be submitted to the financial test—Will it pay? We shall therefore just glance rapidly at this aspect of the question, and see what returns are to be looked for on capital laid out.

Since lucerne is the crop which has for some years past claimed the most attention from irrigators, we may start off by looking at the results to be obtained from that crop.

The most profitable method of working is, speaking generally, by grazing it. It may be fed to dairy cattle or ostriches, or to sheep or cattle for slaughter. In this way returns of 22 to 40 per cent. per annum on the capital invested may be obtained. The favour with which this crop has come to be looked upon is no doubt due, in great measure, to the high net value of produce which is obtained per acre. Reliable figures place its value as pasturage at from £25 to £45 per acre per annum, whilst if made into hay, £15 to £20 per acre may be cleared. Nothing like such returns can be expected from any cereal crops, though they may be equalled, or even exceeded, by fruits or vegetables, but these, particularly the latter, require more labour to produce, are more dependent upon the proximity of a local market, and generally more easy of over production.

It is not right, however, to allow oneself to be carried away by the high values per acre obtained. The real test is the percentage returned on capital invested, and, when looked at from this point of view, the lucerne will not be found to give greatly better results than some other crops. Lucerne requires the best land for growing to perfection. Particularly, the soil must be deep, for the plant sends its roots to a great depth, and it must contain a fair amount of lime. Where soil of suitable quality can be had—and the quantity yet appropriated is a mere fraction of that available—there can be little doubt that lucerne is in many respects a very satisfactory and profitable crop. It has the immense advantage of being a permanent crop which, once established, will, with proper care, continue to yield good returns for many years. It is a very hardy plant, and in case of shortage of water will not suffer permanent damage. Sending its roots deep down in the soil, it will stand a severe drought, and though, of course, it will not yield a crop whilst deprived of water, it will remain healthy, and be ready to respond when water is again available.

All land, however, is not suited for lucerne, and much which is not may yield excellent returns with cereals or other crops. The best return in weight of grain from wheat is probably obtained in the Transvaal, where it is grown under permanent irrigation. The yield averages from eight to ten bags (of 200 lbs.) per acre, the net profit on which may be taken at about £2 to £3. On the Zak River, already referred to, three and a half bags per acre may be taken as an average yield from Zaai dam cultivation, and here again a net profit may be put at about £2 per acre per annum. These yields are averages taking one year with another, and whilst the irrigation in the Transvaal is with perennial water, that on the Zak is with intermittent and uncertain, which in some years fails to come down at all, or in so small quantity that no seed is sown; the district, however, has the benefit of a cheaper if more primitive system of irrigation, which places a lesser burden of cost per acre on the area watered.

The table following shows the value per acre per annum of several crops named, and the percentage returns on capital outlay, giving in each case a fair market value to the land according to the use to which it is put.

For some of the information on which the figures given are based, the author is indebted to Mr. Oscar Evans and other experienced ostrich breeders, and lucerne growers, whose experience is given in a pamphlet, "Money in Lucerne," to the publishers of the same, the Midland Printing and Publishing Company, and also to Mr. Burtt-Davy, Government Botanist.

Hosted by Google

Crop.	Net Value of Crop per Acre.	Capital Invested per Acre.	Return on Capital per cent.	Acres required to Produce Profit of £1,000 per Annum.
Lucerne grazed	£20 to £45	£120	20 to 40	22 to 40
,, hay	£18	£60	30	55
Wheat, Transvaal	£2 to £3	£8 to £10	20 to 35	330 to 500
,, Zak River . . .	£2	£5 to £7	30 to 40	500
It may be of interest to compare with these some figures for dry farming.				
Wheat, Malmesbury . . .	18s.	£3	30	1111
Mealies, Transvaal . . .	£2 to £3	£4 to £5 10s.	40 to 50	330 to 500

The obvious lesson of this table is that although irrigation may not yield a much higher percentage return on capital than other methods of farming, it does enormously increase the productiveness of the land—*i.e.*, whilst it does not increase appreciably the return per £1 invested, it vastly increases the return per acre of land worked. The last column in the table has been added to bring out this feature, and it shows that whereas with dry farming, in order to obtain an income of £1,000 per annum, it would be necessary to work from 300 to 1,100 acres, the same result might be achieved with from 22 to 55 acres of land under irrigation.

This fact is of interest to the individual farmer as indicating a saving on personal wear and tear, and in the amount of labour to be provided, but is even more so to the state as showing how irrigation may serve to render the land capable of more intense cultivation, and so of supporting a greater population.

It seems probable that for some time to come the efforts of the Government must be directed rather to assisting in the development of smaller works, such as those of irrigation boards and farmers, than to initiating extensive schemes.

Several large schemes have been investigated in the past. One to irrigate 40,000 acres was worked up in the Breede River a few years ago, but was not taken very kindly to by the farmers, and there is little doubt that before long quite as large an area will in the same district be put under irrigation by means of several smaller projects.

To the writer it appears that, apart from general guidance and advice, the work which the Government should make its speciality is the storage of surplus waters. That is a matter generally too comprehensive to be tackled by the riparian owners. Even in the hands of Government the distribution of the water will be a matter far from simple, but the longer it is delayed the more vested interests there will be to propitiate.

DISCUSSION.

The Chairman (the Hon. Sir Richard Solomon), in opening the discussion, said he did not intend to criticise the paper, because he did not feel competent to do so, but there were two inferences from facts to which attention had been called in the paper on which he desired to make a few observations. He inferred from certain facts that had been placed before the audience, that, first of all, South Africa needed a much larger white population, and secondly, that the land of South Africa under proper conditions was capable of sustaining a larger white population and able to produce sufficient food-stuffs for the consumption of its own population. He desired in the remarks he wished to make to indicate the steps the Government of the Union were taking in relation to that question. The author had pointed out that within the Union of South Africa, the European population numbered only about a quarter of the aboriginal native population; but a more serious fact was that, judging from the census taken in 1911, the native population since 1904, when the last census was taken, had increased proportionately more than the European population had done, the increase in the former being about 16 per cent. and in the latter about 14 per cent. He had seen it stated, and he believed it to be true, that that was the first time in the history of South Africa when, between the taking of two censuses, the European population had increased less rapidly than the native population had done. He had no hesitation in saying that as far as he could see the native population would go on rapidly increasing. The causes which at one time operated to reduce the native population were happily no longer in existence. Tribal fights could not be tolerated in a

Hosted by Google

country where civilised law prevailed, and it was no longer possible for powerful native chiefs, like Chaka, Dingaan and Lobenguela, to slaughter at their sweet will hundreds and thousands of their subjects. Famine, which at one time frequently reduced the native population, had been entirely eliminated by the constant and increasing demand for native labourers and by the comparatively high wages paid them, especially at the mines at Johannesburg; while intoxicating liquor, so destructive to primitive races, was forbidden to be sold almost everywhere within the Union to the native population. It appeared to him perfectly clear that if the European population in South Africa was to hold its own, and to maintain its supremacy and superiority, there must be accessions to its numbers from outside. In respect of immigration, South Africa was in a different position from Canada and Australia. Many Europeans went to Canada and Australia as farm labourers and ordinary unskilled workers, but in South Africa all the unskilled work on the farms, in the mines, and in the different industrial undertakings was performed by natives. There was a rooted conviction amongst the European population, not only amongst those born on the soil, but those who went to South Africa from this country, that it was degrading to do unskilled work because it was looked upon as black man's work. Personally, he believed that time, and the acute demand for labour, would kill that prejudice, but as long as it continued, there was little or no demand in South Africa for unskilled European labour. But, as the author had stated, there was plenty of land in South Africa of rich soil, and there was a most perfect climate, great assets to a young country which wished to increase its European population. The Government desired to place more land under cultivation in South Africa, and to obtain more European producers. The author had stated that there were imported every year into the Union of South Africa, millions of pounds' worth of food-stuffs, which ought to be grown in the country. During the first ten months of 1911, he found that about one million pounds' worth of wheat and flour had been imported into the Union, and about a million pounds' worth of meat, butter and milk. All those articles could and ought to be produced in South Africa. He had often spoken to farmers in South Africa who had farmed in Australia and New Zealand, and had been told by them that South Africa was a better colony to farm in than either of the other two, and yet Australia and New Zealand exported thousands of pounds' worth of food-stuffs to Europe, while South Africa imported thousands of pounds of food-stuff into the Union. Why was that the case? They had the land, the climate, and the soil, but it was necessary to consider the difficulties that existed in the past to which the author had referred, namely, the difficulties in connection with irrigation and land settlement. He trusted that those difficulties were now of the past. Great struggles had taken place in South Africa, which he hoped were now over. They had to look into the future, and the policy of the future was to prepare the land for settlement by judicious schemes of irrigation, and by extension of railways. A large European population would thus be obtained upon the land, which would successfully cultivate it and produce sufficient food-stuffs, not only for the consumption of the people of South Africa, but for export to the Mother Country. It was natural the question should be asked: What was the policy of the Government going to be in connection with those matters? There was no doubt whatever that they were receiving the serious attention of the Government of South Africa. Railways were being extended throughout the length and breadth of the Union. Fifty years ago he did not suppose there were fifty miles of railway in the whole of the country which now comprised the Union; at the present day there were 9,000 miles in actual use and many hundreds more being constructed; and the demand for railway construction was constant and persistent. Telephones were being constructed to different farms in the country, by means of which it was possible to communicate with the nearest markets; and during the present session of Parliament the Government intended to introduce a Land Settlement Bill, under which power was given to them to appropriate unoccupied Crown lands, of which there were about five million acres within the Union, and also to purchase private land for the purpose of settling people upon it. The Bill also provided for settling the right people on the land, and for giving them easy terms of hiring and of purchase. It was intended to introduce an Irrigation Bill during the present session which modified some of those principles of the common law which the author had stated were so strictly interpreted by courts of law, and which raised very great difficulties in the way of irrigation schemes in a country where severe droughts occasionally occurred; where in many parts the rainfall was insignificant, where the rivers ran in deep channels, and for a considerable portion of the year some of them were absolutely dry, and then after a thunderstorm became raging torrents. The Irrigation Bill also provided for the establishment of water boards and irrigation boards, and, perhaps what was more important than all, authorisation was given to the Government to make loans at low rates of interest to private individuals and to irrigation boards for the purpose of constructing the irrigation works. Perhaps the most important practical step which the Government intended to take, which it had already announced, was to raise a loan of five million pounds for the purpose of land settlement and irrigation works, and for the general development of the agricultural industry. Acts of Parliament looked exceedingly well upon paper, but unless money was available to carry out the objects of the Acts they became dead letters. It was very difficult indeed for a private farmer to make irrigation works of his own; he had to be assisted by the Government, and with the pecuniary assistance which the Government proposed to give to private

Hosted by Google

individuals and irrigation boards he had no doubt that the irrigation which was so essential to the cultivation of the soil in South Africa would progress by leaps and bounds. He therefore thought they might confidently look forward to a great future for the agricultural industry of South Africa, and to the time when the Union would not only produce all the food-stuffs necessary for its own population, but would become one of the principal exporters of those articles to the European markets.

Sir Hanbury Brown, K.C.M.G., said that in these days of powerful navies and world-wide naval strategy, it was a sound principle for every country to grow as much of its own food as it could on its own soil, and not to depend upon possible enemies for any of its food-supply. It seemed from the paper that South Africa had violated that principle. Its mineral wealth had been exploited; its agricultural development had been neglected; but it appeared from what the Chairman had said, that South Africa had repented and was going to mend its ways. It was a country of cultivable soil and of deficient rainfall, and therefore irrigation was the thing needful. The practical question seemed to be where and to what extent the Government should step in and take control of the irrigation. It was a very rash thing for anybody who had not been in South Africa to make suggestions, but, nevertheless, he would mention a few ideas that had struck him on reading the paper, with nothing but the *Times* atlas before him. To one whose experience was of irrigation in Egypt, there were two passages in the paper which contained rather striking statements, one being the statement that almost all the cultivated land lay between 2,000 feet and 6,500 feet above the sea; and the other that the rivers running in deep channels had *very flat slopes* of from 1½ to 3½ feet per mile. When he read the paper he thought that feet was a misprint for inches, the slope of the Nile being only 5 inches to a mile. What the author evidently meant was that the *surface slope of the country* was not steep enough to allow of the water being led out from the deep river channels and brought to the country surface without digging canals of such length as would be inadmissible in the case of small areas on account of the relatively excessive cost, even if the lie of the land would allow of canals of such a length being dug. The fact that the cultivated land in South Africa lay at such a high altitude formed a very strange contrast to the land of Egypt. All the cultivated land in the Delta of Egypt lay between fifty feet and nothing above the sea; and on the west of the Delta near Alexandria there were cultivated lands which were even below the level of the sea. In the Delta of Egypt great difficulty was therefore experienced with regard to the drainage of the country, and much of the drainage water had to be lifted by powerful machinery. In South Africa, with a fall to the sea of 2,000 to 6,500 feet, the irrigation officers would not be met with that drainage difficulty; and for this they might be thankful. With regard to the question of irrigation in South Africa, he proceeded to consider whether there was any field for a big single irrigation project of wide extent, as Indian and Egyptian officers would understand the words "wide extent." He was inclined to think there was one. The Orange River had its source in the Drakensburg Mountains, which were on the east side of the Continent not far from the coast where the rainfall was copious, and the river ran from east to west through lands where the rainfall was deficient. Below the junction of the Vaal with the Orange River there was no important tributary carrying perennial water which came into the parent stream. So that it seemed to him, after studying a small scale-map, that Prieska was not unlikely a favourable place for the head-works of a canal project for the irrigation of the land to the west of it, such as the Government might draw up, execute, and control. With regard to other smaller river systems, excepting perhaps the Limpopo, the best arrangement, it seemed to him, was one that was adopted in France, namely, that the interested parties should form themselves into syndicates, or associations, with power to carry out and work canal systems, with perhaps a grant from the Government and the expert advice of the Government's irrigation engineers. That, he gathered from the paper, was practically the method adopted in South Africa. The associations, he supposed, would be assisted by the irrigation boards, and over them would be the river boards, which he presumed were district irrigation departments with some of the powers of a Government department. That, it seemed to him, was a system which was suitable to the conditions of the smaller river schemes. The concluding sentence of the paper repeated the warning made by Sir William Willcocks in 1901, that the Government should declare all the rivers and natural watercourses to be part of the public domain. It was easy to understand the necessity for that. It was only necessary to imagine two associations, one high up the river and the other lower down, each intent on developing land by irrigation from the river. As soon as the development had reached that stage at which all the available water-supply in the river was utilised for irrigation, then any further development by the upper association must be followed by a decrease in the cultivation of the lower one, and there would be no net gain. The Nile furnished a good illustration of such a situation. During the nineteenth century the summer cultivation of Egypt was developed to such an extent that eventually every drop of the natural flow of the river in summer was utilised in irrigation. There was now a paternal Government in charge of the Sudan anxious to develop the resources of the country. Among the things it wished to develop was the summer irrigation of cotton cultivation. But it was not able to do that without taking water out of the river in summer, and that the Sudan could not be allowed to do without restriction, except at the

Hosted by Google

expense of Lower Egypt. So that the Government kept a tight hand on the River Nile, and the Sudan was only allowed to take out water in the summer to a very limited extent. So, before all else, as a preliminary to any scheme of canal administration, the right of the public to its own natural water-supply must be safeguarded against any exclusive appropriation of it by individuals, and the author had done well to conclude his paper by a reference to that necessity.

MR. R. B. BUCKLEY, C.S.I., said there were two points in the report written by Sir William Willcocks, to which both the author and Sir Hanbury Brown had referred, which seemed to him to bear out a good deal of what had been heard in the author's interesting paper. In one part Sir William Willcocks said: "It is quite obvious that the future development of the agricultural industry in South Africa depends almost entirely upon irrigation." And in another part he said: "When rain is wanted it is generally not there, and when it is not wanted it is invariably present. In a country so situated, the only possible means of development lie in the storage of water when it is present and not needed, and its utilisation by irrigation when it is needed." The two main facts which struck him as having been brought out by the paper agreed with those statements. The author had referred to the extremely variable nature of the rainfall in South Africa, and the condition of some of the rivers which had been cut away by the heavy scour of the floods which occasionally occurred. Most people would admit that two things were absolutely necessary for any irrigation scheme, although, curiously enough, some people who were not acquainted with the details of irrigation would admit the necessity of one, but rarely admit the necessity of the other. It was necessary, in the first place, to have land to irrigate, and, in the second place, water to irrigate with. The audience might think it very absurd of him to say such a thing, but it really was the fact that some people who were not acquainted with irrigation did not seem to think it was necessary to have the water. They thought it was only necessary to have an irrigation officer, and if such a gentleman was obtained it necessarily followed that the water would also be obtained. That was not true. South Africa was a country which eminently desired irrigation, but it was a country which did not lend itself generally to successful schemes of large irrigation; it lent itself in many ways to small and comparatively restricted projects. Sir Hanbury Brown had referred to the possibility of irrigation from the Orange River. Personally, he believed that was the only large river from which any extensive irrigation was possible. Sir William Willcocks in the extract he had read referred to the fact that if the resources of South Africa were to be developed by means of irrigation it was necessary to store the water. It was very difficult indeed to get people to believe that it was impossible to store all the water that came down from the sky. To illustrate the point of the very varying amounts of water which could be obtained from the same volume of rainfall, the following particulars with regard to a reservoir at Nagpur would be of interest. On one occasion a rainfall of 2·20 inches fell on the catchment area of the reservoir in eighty minutes; on another occasion in the same year a rainfall of 2·24 inches fell in precisely the same time. One rainfall put into the reservoir not a single drop of water independently of that which actually fell into the reservoir itself; the second rainfall poured in 98 per cent. of the water which fell on the catchment. The explanation of that apparently astonishing fact was extremely simple. The first fall occurred when the catchment, which was a rocky one, was very dry, and was to a large extent at once dissipated in vapour from the soil or absorbed by the crevices in the land. On the second occasion the land had been wetted for some time before the rainfall, and the whole of it flowed off. Somewhat similar experiences had occurred in Cape Colony. He recently came across a case mentioned by Mr. Newry, in which a certain catchment of thirty-six square miles had a rainfall of 19 inches in the year, and about 20 per cent. of the water was obtained off it; while in another year there were 33 inches of rainfall and only 9 per cent. of it came off. It was a fact that a dry year, when water was most required for irrigation, was the very time when it was most difficult to get it into the reservoir. In a year when the rainfall was heaviest, which was the time when water was least wanted for irrigation, it was comparatively easy to get the water into the reservoir. So that a reservoir was not always a complete remedy for irrigation troubles, and he therefore desired to utter a word of warning with reference to the construction of reservoirs in South Africa. The rainfall in South Africa was generally much dispersed. With a light rainfall a very small amount of the water came off into the reservoir. Now and again very heavy showers occurred which produced heavy floods, but he was told they were rare in South Africa. In any project for the construction of a reservoir in South Africa it must be borne in mind that it was extremely doubtful whether the amount of water would be got into it which had been calculated in the paper. It was stated that 5 per cent. of the rainfall was likely to be conserved. Personally, he confessed he was very doubtful on that point. There were a great many reservoirs in India, mainly in the Province of Bombay. In that Province the rain did not fall, as it fell in South Africa, widely dispersed over the year; it all fell practically in four or five months, which proved that it was much easier to collect the water in that time than when it fell in twelve months. But the experience of 175 observations, extending over twelve or eighteen years, of various reservoirs in India, showed that even in those four or five months not more than 10 per cent. of the rainfall, which during those months

was about as great as was obtained in South Africa during the whole year, went into the reservoir. There were cases in which 20 per cent. of the water was obtained, and others in which 40 per cent. was obtained, but in many cases only 9 per cent. was obtained. That was borne out by some observations made in the Transvaal by Mr. Strange, who, in writing with regard to observations that had been going on for some time, said:—"The returns are very disappointing, as they show that but an insignificant percentage of the rainfall found its way into the rivers." He therefore thought that if reservoirs were constructed in South Africa disappointing results would follow in many cases. He noticed the author had stated that in Cape Colony the water-supply would probably be sufficient to irrigate 2,700,000 acres. Experience in Egypt and India had shown that in the irrigated tracts a population of something like one person to an acre was required to do it efficiently. In Egypt there were something like 600 people to the square mile, and in the parts of India which were largely irrigated there were about 400 to 500 to the square mile. To deal with 2,700,000 acres of irrigation in Cape Colony would require more than the entire present white and black population of the whole Colony to be turned on to the land, so that if that forecast of 2,700,000 acres was to be realised it meant that a large increase in the population must be obtained.

Mr. R. E. Brounger said that, as a railway engineer, he had been connected with the construction of railways in South Africa, and in that capacity had experienced the difficulties and privations which lack of water involved. When the railway was being built from Cape Town to Kimberley, across the Karoo, many an instance occurred in which water had to be carted forty miles for the making of the mortar for the construction of bridges and culverts, and for the workmen to drink. An amusing story was told of the difficulties connected with the absence of water in Kimberley in the early days, it being said that some of the wealthy people who were able to afford baths used to buy two or three dozen bottles of soda water and have a bath once a month.

Sir Clement Hill, K.C.B., K.C.M.G., M.P., proposed a hearty vote of thanks to the author for his most interesting and instructive paper.

Sir Colin Scott Moncrieff, K.C.S.I., K.C.M.G., in seconding the resolution, at the same time expressed the thanks of the audience to the High Commissioner for his kindness in occupying the chair.

The resolution of thanks having been carried with acclamation,

Mr. W. A. Legg, in reply, thanked those present for their kind vote of thanks and the cordial reception they had given the paper. In reply to Sir Hanbury Brown's remarks with regard to the slope of the rivers, when he (the author) said it was a small slope, that must be taken in conjunction with the fact of the channels being very deep, and also that the water, when it did run in those channels, did not run to a very great depth as a rule, and was perhaps from 20 to 30 feet below the surface of the adjoining ground which it was proposed to irrigate. That made a slope of even 2 or 3 feet per mile rather a small one when it was necessary to lift the water from such a great depth below the surface of the ground to get it on to the land. In dealing with the question of storage, Sir Hanbury Brown suggested that the Government should take control of the surplus water. That would be the ideal thing to do, but it might not prove to be quite such an easy thing to carry out in South Africa as it was in Egypt, because there were so many vested interests in South Africa which would have to be dealt with before that could be done on a large scale. He desired to say to Mr. Buckley that the rainfalls which were shown in the table were typical of the Karoo country, and not of the whole of South Africa. In many parts of the country a rainfall of two inches in a day very often occurred, although it was not at all common on the Karoo.

NINTH ORDINARY MEETING.

Wednesday, February 7th, 1912; Lord Sanderson, G.C.B., K.C.M.G., Chairman of the Council, in the chair.

The following candidates were proposed for election as members of the Society:—

Bieber, Miss Caroline Frances, F.Z.S., 25, Wetherby-gardens, South Kensington, S.W.

Heaven, Frances Gyde, 132, Gresham House, Old Broad-street, E.C.

Lee, Ivy L., 24, Throgmorton-street, E.C.

Randall, Wilfrid Levison, F.S.A.M., Port House, Brimscombe, Gloucestershire.

Wallis-Tayler, Alexander James, Assoc.M.Inst.C.E., "Esquimalt," Robin Hood-lane, Sutton, Surrey.

The following candidates were balloted for and duly elected members of the Society:—

Buchanan, James, J.P., Lavington Park, Petworth, Sussex.

Jones, Harry, 32, Acfold-road, Fulham, S.W.

The paper read was—

THE INFLUENCE OF OZONE IN VENTILATION.

By Leonard Hill, M.B., F.R.S.,
and
Martin Flack, M.A., M.B., B.Ch.

The good effects which result from efficient ventilation and open-air treatment are generally supposed to be due to the chemical purity of the air. They are due really to the movement,

Hosted by Google

coolness, relative humidity of the air, and to the ceaseless variation of these qualities. The ventilating engineer has hitherto followed a great illusion in thinking that the main object to be attained is chemical purity of the air. The heating engineer has sought after an equally great illusion in striving to give us a uniform summer temperature (Pembrey). The ventilating and heating engineers primarily should aim at giving us air which is cool, of proper relative humidity, and which moves so as to vary the cutaneous state of the body. Our comfort and discomfort in crowded rooms and shut-up places depends, not on the chemical purity of the air, but, to a minor degree, on the influence of the smell of the air on the olfactory sense, and, to a vast degree, on the influence of the temperature, relative humidity, and the variations of these qualities of the air, which act on the great field of cutaneous sensibility.

It is needless to point out that our sense of well-being depends to a very great degree on the comfortable condition of our skin, and yet the ventilating and heating engineers have paid little attention to this. While asserting that the chemical purity is of no account, we make the proviso that the air is only altered by the presence of human beings, and is neither rendered poisonous by the escape of coal gas, or other noxious trade product, nor deoxygenated by the oxidative processes of the soil, as it is in mines. We are speaking of the discomfort and ill-health caused by the deficient ventilation of, or bad methods of heating, dwelling-houses, schools, factories, theatres, chapels, etc.

The chemical purity of the air can be considered from three points of view, the concentration of CO_2, the concentration of O_2, the supposed presence of organic poison exhaled in the breath.

Owing to the fact that a percentage of CO_2 is not legally permissible in factories which exceeds a very few parts per thousand, it is commonly supposed that any greater excess of CO_2 acts as a poison.

The truth of the matter is quite otherwise; for, whatever the percentage of CO_2 in the atmosphere may be, that in the pulmonary air is kept constant at about 5 per cent. of an atmosphere by the action of the respiratory centre. It is the concentration of CO_2 which rules the respiratory centre, and to such purpose as to keep the concentration both in the lungs and in the blood uniformly about the same. This fact, which was first firmly established by Dr. John Haldane, is of fundamental importance.

It is impossible that any excess of CO_2 should enter into our bodies when we breathe the air of the worst-ventilated room in which the percentage of CO_2 assuredly does not rise above 0·5 per cent., or at the outside 1 per cent. The only result from breathing such an excess of CO_2 is a slight and unnoticeable increase in the ventilation of the lungs. The increased ventilation is exactly adjusted so as to keep the concentration of CO_2 in the lungs at the normal 5 per cent. of an atmosphere. The very same thing happens when we take gentle exercise, and produce more CO_2 in our bodies; the pulmonary ventilation is then slightly increased, and thus the CO_2 concentration in the blood and lungs is kept at the same uniform level. At each breath we rebreathe into our lungs the air in the nose and large air-tubes (the dead space air), and about one-third of the air which is inhaled into the lungs is "dead space" air. Thus, no man breathes in pure outside air into his lungs, but air contaminated perhaps by one-third, or (on deep breathing) by one-tenth with expired air. When a child goes to sleep with its head partly buried under the bed-clothes, and in a cradle with the air confined by curtains, he rebreathes the expired air to a still greater extent, and so with all animals that snuggle together for warmth's sake. Not only the new-born babe sleeping against its mother's breast, but pigs in a stye, young rabbits, rats and mice clustered together in their nests, young chicks under the brooding hen, all alike breathe a far higher percentage than that allowed in our factories by the officials of the Home Office. To rebreathe one's own breath is a natural and inevitable performance, and to breathe some of the air exhaled by another is the common lot of men who, like animals, have to crowd together and husband their heat in fighting the inclemency of the temperate and Arctic zones. By a series of observations made on rats confined in cages with small ill-ventilated sleeping chambers, we have found that the temperature and humidity of the air—not the carbonic acid and oxygen concentration of the air—determines whether the animals stay inside the sleeping-room or come outside. When the air is cold, they like to stay inside, even when the carbonic acid rises to 4 per cent. or 5 per cent. of an atmosphere. When the sleeping chamber is made too hot and moist they come outside.

In breweries the men who tend the fermentation vats work for long hours in concentrations of CO_2 of 0·5 to 1·5 per cent. (Lehmann). Such men are no less healthy and long-lived

Hosted by Google

than those engaged in other processes of the brewing trade. In the Albion Brewery we analysed on three different days the air of the room where the carbonic acid gas, generated in the vats, is compressed and bottled as liquid carbonic acid. We found 0·4 per cent. to over 1 per cent. of carbonic acid in the atmosphere of that room. The men engaged therein worked twelve-hour shifts, having their meals in the room. They had followed this employment for eighteen years, and without detriment to their health. It is only when we come to the higher concentrations of CO_2, such as 3 per cent. to 4 per cent. of an atmosphere, that the respiration is increased so that it is noticeable to the individual himself, and such percentages, of course, diminish the power to do work; for the excess of CO_2 produced by the work adds its effect to the excess in the air, and the limit of panting is soon reached. Thus the power to work is checked. Divers who work in diving dresses, and men who work in compressed-air caissons, constantly work in concentrations of CO_2 higher than 1 per cent. of an atmosphere, and so long as the CO_2 is kept below 2 per cent. to 3 per cent. of an atmosphere, they are capable of carrying out efficient work.

It results, then, from what we have said, that concentrations of CO_2, such as occur in the most crowded and worst-ventilated rooms, are of no account. Forced to admit this fact, the hygienist has fallen back on the hypothesis that organic chemical poisons are exhaled in the breath, and that the percentage of CO_2 is a valuable guide as to the concentration of these. It is necessary, he says, to keep the CO_2 below 0·1 per thousand, so that the organic poisons may not collect to a harmful extent.

Before we turn to the discussion concerning the supposed existence of these organic chemical poisons, we will deal with the question of oxygen. The oxygen in the worst-ventilated schoolroom, chapel, or theatre, is never lessened by more than 1 per cent. of an atmosphere. The ventilation through chink and cranny, chimney, door and window, and the porous brick wall, suffices to prevent a greater diminution of the oxygen concentration. Now, in all the noted health resorts of the Swiss mountains, such as St. Moritz, the concentration of oxygen is lessened considerably more than this. On the high plateaux of the Andes there are great cities: Potosi, with 100,000 inhabitants, is at 4,165 metres (barometric pressure about 450 mm. Hg.); railways and mines have been built even at altitudes of 14,000 to 15,000 ft. Owing to the nature of the chemical combination of oxygen with hæmoglobin, man can adjust himself to very great variations in oxygen concentration. At Potosi girls dance half the night, and toreadors display their skill in the bull-ring. We have watched our students, shut in an air-tight chamber, until they came to breathe air containing only about 16 per cent. of oxygen and 3½ per cent. of carbonic acid, and seen their puzzled look when they found they were unable to light a match and smoke a cigarette. There was then too low a percentage of oxygen to support combustion, but of this they were quite unaware. All the evidence goes to show that it is only when oxygen is lowered below a pressure of 14 per cent. to 15 per cent. of an atmosphere, that signs of oxygen want arise. A diminution of 1 per cent. of an atmosphere has not the slightest effect on our health or comfort.

We must now discuss the evidence for the existence of organic chemical poison in the exhaled breath. The evil smell of crowded rooms is accepted by most as unequivocal evidence of the existence of such. This smell, however, is only sensed by, and excites disgust in, one who comes to it from the outside air. He who is inside and helps to make the "fugg" is both wholly unaware of, and unaffected by, it. Fluegge points out, with justice, that while we naturally avoid any smell that excites disgust and puts us off our appetite, yet the offensive quality of the smell does not prove its poisonous nature. For the smell of the trade or food of one man may be horrible and loathsome to another not used to such. The sight of a slaughterer and the smell of dead meat may be loathly to the sensitive poet, but the slaughterer is none the less healthy. The clang and jar of an engineer's workshop may be unendurable to a highly-strung artist or author, but the artificers miss the stoppage of the noisy clatter. The stench of glue-works, fried-fish shops, soap and bone manure works, middens, sewers, become as nothing to those engaged in such, and the lives of the workers are in no wise shortened by the stench they endure. The nose ceases to respond to the uniformity of the impulse, and the stench clearly does not betoken in any of these cases the existence of a chemical organic poison. On descending into a sewer, after the first ten minutes, the nose ceases to smell the stench; the air therein is usually found to be far freer from bacteria than the air in a schoolroom or tenement (Haldane).

If we turn to foodstuffs, we recognise that

Hosted by Google

the smell of alcohol and of Stilton or Camembert cheese is horrible to a child or dog, while the smell of putrid fish—the meal of the Siberian native—excites no less disgust in an epicure, who welcomes the cheese. Among the hardiest and healthiest of men are the North Sea fishermen, who sleep in the cabins of trawlers reeking with fish and oil, and for the sake of warmth shut themselves up until the lamp may go out from want of oxygen. The stench of such surroundings may effectually put the sensitive, untrained brain-worker off his appetite, but the robust health of the fisherman proves that this effect is nervous in origin, and not due to a chemical organic poison in the air. The supposed existence of organic chemical poison in the expired air is based upon experiments of Brown-Sequard and d'Arsonval. They injected into guinea-pigs and rabbits either the condensation water obtained from the breath, or water which they used several times over to wash out the trachea of dogs. The water was injected subcutaneously and in large amounts, and produced in their hands signs of illness, collapse and death.

These experiments have been repeated by many others, and with negative results by those whose methods of work demand most respect—Dastre and Loye, Van Hofmann Wellenhof, Lehmann and Jessen, Haldane and Smith, Weir Mitchell and Borgey, etc. A few confirmatory results have been obtained by methods of experiment which are truly absurd in their conception. One to two cubic centimetres of condensation water (obtained by breathing through a cooled flask) have been injected into a mouse weighing 13 grams or so. This is equivalent to injecting five litres of water into a man weighing 65 kilos. Who would not be made ill by the injection of about nine pints of cold water beneath his skin? It has been shown that injections of pure water alone in doses of over one cubic centimetre may make a mouse ill (Inaha). Such experiments are ridiculous, and deserve not a moment's attention.

In the case of Brown-Sequard and d'Arsonval's experiments they injected from 4 to 44 cubic centimetres into guinea-pigs and rabbits, either directly into the circulation or subcutaneously. Using the washings of a dog's trachea, or the condensation fluid obtained from the breath, they could not fail to inject traces of the proteins of the saliva. A second injection of such into the same animal might produce the well-known anaphylactic shock. By subcutaneous injection of a foreign protein an animal becomes sensitised, and may be poisoned by a subsequent injection of the same. The sensitivity may be produced by extraordinary small doses—*e.g.*, one millionth of a 1 c.c. of serum. Anaphylaxis is never produced by the injection of protein taken from the same species of animal, nor can it be produced by eating foreign protein. There is no reason to suppose that it can be produced by breathing into the lungs traces of a foreign protein. Quite recently Rosenau and Amos have published experiments which seem to show that guinea-pigs can be sensitised by the injection of the condensation water of human breath, so that anaphylaxis is produced in these pigs by a subsequent injection of a trace of human serum. These observers breathed for six to ten hours through a glass tube fitted with a plug of glass wool. Owing to the method employed it seems certain that saliva must have wetted the glass wool, and, carried on in "droplet" form, contaminated the condensation water. Breathing through a tube leads to an expulsion of saliva which does not occur in natural breathing. The guinea-pigs, as we might expect, therefore became sensitised to human protein by the injection of the condensation water containing traces of salivary protein. The authors, however, do not take this view, and think that their results afford evidence in favour of the exhalation of a volatile protein—an organic chemical poison. We cannot admit this view. The question before us is—Do men breathe out a substance poisonous to man? If there were anything in the claims of the American authors, we should expect to find rats, which dwell in the same confined cage and breathe each other's breath, sensitive to the injection of a trace of each other's protein. We are informed, by those who study the phenomena of anaphylaxis, that no such sensitivity can be shown.

After studying the literature on this subject we are convinced that there is no positive evidence which demonstrates the poisonous nature of the condensation water obtained from the breath. We go further and say there is at present no trustworthy evidence of the existence of any such poison in the exhaled air. Brown-Sequard sought to substantiate his views by carrying out a different series of experiments. He arranged rabbits in a series of chambers, and led the air from one chamber to another, so that each succeeding chamber received the vitiated air from the one before it. In the end cage rabbits died, but if the air received into this cage were passed through sulphuric acid the rabbits remained alive.

Hosted by Google

These experiments have been repeated with the greatest care by Haldane and Lorrain Smith; also by Beu, Rauer, Lübbert and Peters, Billings, Weir Mitchell and Borgey, Formanek, etc. It has been proved conclusively that no harm results so long as a sufficient air current is maintained to keep the carbonic acid below a poisonous amount. The animal in the last cage dies when the CO_2 reaches 10 to 12 per cent. If the CO_2 is kept down the animal in the last cage puts on weight and thrives as well as the animal in the first cage. Of course, it is necessary in such experiments to clean the chambers daily, and supply the animals with suitable food and bedding. We have repeated the experiments, in one case leading the air from a chamber containing three rats through a chamber containing a guinea-pig, and in another case leading the air from a chamber holding three rats through another chamber also holding three rats. The chambers were daily cleaned and fresh dry hay and food were put within. The guinea-pig lived in an atmosphere containing about $3\frac{1}{2}$ per cent. of carbonic acid, and put on nearly 100 grams in weight in three weeks, in this respect doing quite as well as another half-grown guinea-pig kept under normal conditions. The rats in the other second chamber did no less well. Thus the evidence obtained from this kind of experiment as to the existence of a poison in expired air is wholly negative. Brown-Sequard's result must be ascribed to suffocation arising from failure in experimental method. We accidentally lost four of our animals from suffocation after the experiment had continued for a month, owing to the chinking of a tube and consequent interruption of the air current. Benedict has shown that a man can live many days in a closed chamber in comfort without damage to his health, having not the slightest cognizance of any defect in ventilation, when the ventilation is so reduced that the carbonic acid accumulates in the chamber up to 1 per cent.—that is to say, so long as the air in the chamber is kept cool and dry. We have enclosed eight students in a small chamber holding about three cubic metres of air and kept them therein until the CO_2 reached 3 per cent. to 4 per cent., and the oxygen had fallen to 17 or 16 per cent. The wet-bulb temperature rose meanwhile to about 85° F., the dry-bulb a degree or two higher. The discomfort was very great, but this was relieved to an astonishing extent by putting on electric fans placed in the roof, whirling the air in the chamber, and so cooling the bodies of the students.

In a crowded room the air confined between the bodies and clothes of the people is almost warmed up to body temperature and saturated with moisture, so that cooling of the body by radiation, convection by evaporation, becomes almost impossible. This leads to sweating, wetness and flushing of the skin, and a rise of skin temperature. The blood is sent to the skin and stagnates there instead of passing in ample volume through the brain and viscera. Hence arise the feelings of discomfort and fatigue. The fans in our chamber whirled away the blanket of stationary wet air round their bodies, and brought to the students the somewhat cooler and drier air in the rest of the chamber, and so relieved the heat stagnation from which they suffered. The relief became far greater when we allowed cold water to circulate through a radiator placed in the chamber, and so cooled the air of the chamber about 10° F.

Messrs. R. A. Rowlands and H. B. Walker have carried out, with us, numerous experiments in this chamber. They have performed measured amounts of work (raising a weight) under varying conditions of temperature moisture, and with varying percentages of O_2 and CO_2 in the chamber.

As a measure of the exhausting effect of the work, we have counted the frequency of the heart-beat in the first, second and third minute after the completion of the work. When the work is done without over-fatigue the frequency of the pulse, which is accelerated by work, quickly returns to normal. Our results show that increased percentages of CO_2, and diminished oxygen percentages of 2 per cent. to 3 per cent. and even 4 per cent. to 5 per cent., have little effect in modifying the frequency of the pulse, while the temperature and humidity of the air have a profound effect. The feelings of discomfort depend on the excessive heat and humidity, and are relieved by cooling and whirling the air in the chamber. If we suddenly raised the percentage of CO_2 in the chamber up to 2 per cent. we found the subjects inside were quite unaware of this. If we sat outside and breathed through a tube the air in the chamber we felt none of the discomfort which was being experienced by those shut up inside. Similarly, if one of those in the chamber breathed through a tube the pure air outside he was not relieved. Similar experiments were carried out by Paul, and with like results. The cause of the discomfort is thus proved to be due to the excessive heat and humidity, and absence of movement of the air. Studying the

Hosted by Google

ventilation of sleeping-cars, T. R. Crowder finds that in these cars, called "close" or "stuffy," the temperature invariably is high. There has sometimes been an unpleasant odour. A high temperature renders this more noticeable. The most marked offensiveness noticed was in a day coach, where "the air was of such a degree of chemical purity as to indicate ideal ventilation by any standard that has ever been proposed. The car was hot and had many filthy people in it." Perfect comfort has been found associated with the highest chemical impurity in other cars.

After healthy and clean students have been shut in our chamber we find there is no offensive smell in the confined air.

Ventilation cannot get rid of the source of a smell, while it may easily distribute the evil smell through a house.

As Pettenkofer says, if there is a dungheap in a room, it must be removed. It is no good trying to blow away the smell. Houses and people and their clothes and bodies must be made clean, and latrines and kitchens placed on the top of houses, or outside them, and on the windward side. There is yet another aspect of ventilation which we have not yet discussed, viz., bacterial infection. Catarrhal infections are spread by the expulsion of droplets of saliva when speaking, coughing or sneezing. During quiet respiration the exhaled breath is practically sterile, for the wet mucous surfaces of the respiratory tract catch all the inhaled bacteria, and no "droplets" are exhaled. Can we lessen the "droplet" infection by ventilation? Fluegge concludes, from the results of his admirably contrived experiments, that we cannot. He says a current sufficient to drive out such droplets cannot be borne by the inhabitants of the room. A moderate ventilation current tends to keep the droplets suspended in the air. In a still room they soon fall to the ground, and, clinging to floor and furniture, may be wiped up next morning and removed by the housemaid.

We cannot hope to prevent infection in crowded railway carriages, theatres, chapels, schools, etc. The epidemics of common colds that sweep through the community show this only too well.

It is impracticable to isolate all those suffering from colds, but we can teach them at least to cough and sneeze into a handkerchief, and perhaps even talk with a handkerchief held in front of their mouths. Above all, we must seek to keep up our immunity and resist infection. Immunity depends on the quality and flow of the blood, the supply of immunising substances in the tissue lymph, the activity of the ciliated epithelium and phagocytes which form a second line of defence against bacteria. The state of all these defensive mechanisms of the respiratory membranes are modified by the temperature and relative humidity of the air. Exposure to over-heated dry air dries up not only the skin but the membranes of the nose and throat, and so lessens immunity.

Exposure to over-heated moist air brings the blood into the skin, lessens the circulation through the viscera, and deprives us of the stimulating effect of cold on the cutaneous nerves, decreases the evaporation from the respiratory tract, diminishes the muscular activity, and so the amount of oxygen breathed in and food eaten, and thus altogether lowers the plane of our existence. Hence arise diminished health, strength, and increased susceptibility to catarrh. Those who habitually expose themselves to cold rarely take cold.

Confinement in over-heated, windless air, which too often pervades places of business and amusement, is one of the chief causes of the depressed physical and mental vigour of town dwellers. The evidence of daily life proves that those who take hard exercise in the outside air for some hours a day escape these ill effects. The health of sailors and country labourers shows us that sleeping in hot, confined and ill-ventilated quarters is of no consequence if the working day is spent in the open air. It is persistent exposure to the uniformity of warm, windless air which is the cause of the mischief. The conditions of great cities tend to confine the worker in the office all day, and to the heated atmosphere of the club, cinema show, or music-hall in the evening. The height of the houses prevents the town dweller from being blown upon by every wind of heaven, and, missing the wonderful exhilaration of the cool, moving, open air, he repels the dull uniformity of his existence by the moving pictures of the showman and by tobacco.

We have now dealt with the general principles which ought to control the practice of the heating and ventilating engineer. The old English methods of open fire and open window have very much to recommend them. By the open fire air is kept moving and cool air is brought in; the heating is by radiation, and uniformity of the conditions of temperature in the room is prevented. On the other hand, the

Hosted by Google

impulsion of hot air into a room is the most objectionable of all the systems employed. A cool air and radiant heat are the ideal; the hot-air system give us neither. In cold weather the heated air becomes excessively dry. The vigour and health of children in America have been seriously undermined by the impulsion of hot "desert air" into the schools.

We are now in a position to examine the uses of ozone in ventilation. Ozone is represented by O_3, and differs from the oxygen molecule, O_2, by the addition of a third atom of oxygen, which is loosely bound and has powerful oxidising properties. It corrodes cork, rubber, and other organic substances, and oxidises iron, copper, and even silver when moist, and dry mercury, and iodine. Galvanised iron tubes or glass can be used for the conductance of ozonised air. Traces of ozone are found in the atmosphere after thunderstorms, produced by the effect of the electric discharge on atmospheric oxygen. It is said that traces of ozone exist in sea and mountain air. Ozone is generated by the silent discharge of high-tension currents from one plate of metal to another across a sheet of insulating material. In the Ozonair apparatus demonstrated by us the metal plates are sheets of fine gauze separated by micanite. The discharge takes place from the multitude of points on the gauze, and this equalises the tension at which the discharge takes place, prevents sparking and the formation of oxides of nitrogen. These oxides contaminate the ozone which is formed when ordinary smooth plates are employed, for the discharge then takes place at a few rough points at a far higher tension and with sparking. It is said to be the sparking discharge in air which causes the oxides to form. Each complete element of the Ozonair apparatus consists of a thin sheet of micanite, covered on each side by a square of gauze. The air can be made to pass by a series of baffle plates over a series of these elements. There are over 230,000 round projections to the square foot of the gauze, from which discharge takes place. The gauze is made of an aluminium alloy of forty meshes to the inch.

The Ozonair Company have placed their apparatus at our use, and we must thank Mr. Edward L. Joseph for his courtesy and assistance in the carrying out of our inquiry. The concentration of ozone can easily be determined by aspirating a 10 litre sample of the air through an acidulated 1 per cent. solution of potassium iodide. A little fresh starch solution is added to this. The ozone turns it blue. Titration is carried out with a standard solution of hyposulphite of soda.

On exposing mammals to different concentrations of ozone in our chamber, we have found they may be killed by prolonged breathing of concentrations of about twenty parts per million. The cause of death is an acute irritative inflammation of the respiratory tract. After death congestion of the lungs is found. The ozone in such concentrations causes the eyes to water and makes one cough. It is so irritative and unpleasant that no one would think of continuing to breathe it. Thus a man cannot be poisoned unawares by a dangerous concentration of ozone. He will certainly remove himself from its presence. No harm results from breathing such concentrations for a short period. A slight irritation of the respiratory tract and some sneezing and coughing, and perhaps headache, are the only penalties. The danger signals are clearly set by ozone, and anyone must naturally obey them. When ozone is employed in ventilation it is arranged in such a concentration as to produce none of these symptoms of irritation.

Oxygen in high concentrations (at two or three atmospheres of pressure) is also a poison, and produces not only acute congestion of the lungs but convulsions. Unlike ozone, oxygen produces no preliminary irritative effect. The breathing of ozone in suitable weak concentrations is no less safe than the breathing of proper concentrations of oxygen. Certain insects are comparatively immune to the effects of high concentrations of ozone. For example, we have found that fleas stand exposure to about one hundred parts per million for five hours. This is very unfortunate. Had these parasitic insects only proved highly susceptible we should have found in ozone a clean and ready method of attack.

Ozone can be used in high concentrations for sterilising water; and herein is to be found one of its most valuable uses. The water is not only sterilised but oxygenated, and ozone can be used, therefore, with great advantage to keep the water of aquaria in good condition. Ozone has been successfully applied as the means of purifying the water-supply of several towns, both abroad and in this country. Where the water-supply is contaminated and the source of electric power is cheap, no better or simpler method can be employed. Ozone is a most powerful deodoriser. It takes away all disagreeable smells. Whether it destroys them or prevents the nose smelling them, is of little importance. The psychical effect is the same—

Hosted by Google

the disgust due to the evil smell disappears. Ozone itself has a peculiar smell. It reminds one of the fumes of nitric acid, and whether the smell is that of ozone or minute traces of oxides of nitrogen, it is difficult to say. The nose may detect what the analytical methods of the chemist fail to show. By the smell we can detect concentrations of far less than one part in a million, and the smell is the safest and easiest guide to a suitable concentration. Ozone should be present in the air for continuous breathing in concentrations not greater than that scarcely perceptible to the smell. Concentrations of even one part in the million are too irritative, and quickly depress the metabolism and lower the temperature of rats, and are unpleasant to man. Very weak concentrations, barely perceptible to the smell, have no ill effects, but destroy the effect of unpleasant smells and give a certain tang or quality to stuffy air which relieves its monotony and uniformity.

It is in this respect that ozone has its use. There exist in modern conditions of life so many trade shops, tube railways, cold meat stores, etc., where the employees are exposed to a persistent, uniform and depressing smell. The air in many buildings is made to smell by the heating appliance used. The addition of ozone takes away the smell and relieves the monotony of such air, and, as the Ozonair apparatus can, by the turning of a switch, be put in or out of use, the uniformity of the atmospheric conditions can thus be frequently changed. The ozone, no doubt, exerts its effect both on the cutaneous and respiratory nerves.

We have not been able to obtain any evidence that ozone in weak concentrations influences the respiratory metabolism of the resting man. We have studied the effect of ozone both on animals and on ourselves, estimating the amount of oxygen used up and carbonic acid produced during successive periods of time when air or ozonised air was breathed.

The rate of oxidation of the human body is set by the nervous system, which controls the activity of the body. Breathing pure oxygen in place of air has no effect on the metabolism of the man at rest. It will increase the metabolism of a man doing hard work, but only in the case of his working so hard that he suffers from a shortage of oxygen when breathing air. The body, unlike a fire, cannot be fanned up to burn faster. The living substance works at its own rate independent within wide limits of the changing conditions of the outside world. We should not expect, therefore, that ozone would stimulate the metabolism of the resting man. By altering the unpleasant uniformity of a close atmosphere it may help an employee to work more briskly. In high concentrations, ozone, just as high concentrations of oxygen, depresses the metabolism because it is toxic to the cells of the respiratory tract. The ozone which is breathed into the lungs is caught by the wet mucous membranes and none of it is exhaled. It is, no doubt, used up there in an oxidative process of the tissues. It is excess of such oxidative process which damages the cells lining the respiratory tract, when either too great a concentration of ozone (or oxygen) is breathed. There is no evidence that ozone reaches the blood, or that it has any other influence on the body. The effect which ozone in weak concentrations has on the olfactory nerves, and those of the skin and respiratory tract, is the justification for its use in ventilation.

It seems to us that the addition of ozonised air to the Central Tube Railway has improved the conditions there. The unpleasant characteristic smell of the Tube has been diminished, and the monotonous quality of the air improved.

DISCUSSION.

The Chairman (Lord Sanderson), in opening the discussion, said the audience was very much indebted to the authors for the strikingly original way in which they had explained scientifically a good many things he had not understood. They had explained why people had been very frequently comfortable under certain circumstances, when they were scientifically informed that they ought to be very much the reverse; and why they had frequently suffered a great deal of discomfort when much trouble had been taken to make them comfortable. Personally, he was not competent to discuss the subject scientifically, but he wished to offer a few unscientific observations which confirmed the authors' views. He remembered, about thirty years ago, going for a long drive in a closed landau in company with a venerable peer and two ladies who were almost his contemporaries. Snow was on the ground at the time and there was a hard frost. When the drive commenced the old gentleman said, "What are we to do about the windows? My experience is that it is always better on these occasions to keep them shut until they get clouded over, and then drop the windows a bit and let in a stream of cold air." That plan was carried out, and none of the party caught any colds. The committee rooms of the House of Lords were most scientifically ventilated, but he confessed that in March, when sitting in those rooms, he always longed to be allowed to sit in his robes, while in midsummer he would prefer to be dressed in an Indian shawl and a sash. In July, two or

Hosted by Google

three years ago, he remembered an occasion when all the windows in one of the committee rooms were fully shut, and the electric fans were working as hard as they could, pumping hot air out of the room. Counsel, who were dressed in wigs and gowns, and some of whom were of majestic dimensions, felt the heat very much, and their tempers became extraordinarily short. At last, notwithstanding the protest of the engineer, he ordered all the doors and windows to be opened; and the effect, both morally and physically, was quite remarkable—it was beneficial to the highest degree. After that he began to think what it was that constituted the great advantage of fresh air, and he came to the same conclusion as the authors. In the first place, it was fresh instead of being cooked; and, in the second place, it came in in little gusts at different temperatures, in different directions, and with different force. His own idea of the perfection of ventilation was that the walls of a room should be full of holes, and that outside there should be a man with a keyboard which he would play upon like an organ, thus letting in little puffs of air, there being holes in the ceiling to carry away the bad air, but he was afraid his plan was not practicable. Everybody had a different idea of what was an agreeable and wholesome temperature; in fact, he had known a case in which the comfort of married life had been destroyed because the husband and the wife respectively enjoyed temperatures which made the other ill. In rooms where one sat for any length of time there was an absolute necessity for a little motion, even if it was only fidgetting. He had always advised friends not to write near an open window in cold weather, but to have the room heated to a little higher temperature than would otherwise be the case; but that necessity was avoided if the occupant of the room moved about to a certain extent. The late Lord Derby told him the story of a man who, to overcome the difficulty, put the blotting-pad at one end of the room and the ink-pot at the other. Nowadays, it was quite sufficient to have a telephone in the room. With regard to the question of smells, there was a French proverb to the effect that the things that smelled were not the things that killed: it was the things that did not smell that killed. That proverb had given him a great deal of consolation whenever he had been walking about the streets of some Continental towns, or travelling along the canals of Holland. It was advisable to take an ozoniser with one on such occasions. The authors had given a very clear idea of what ozone was, and what it smelt like. Some people had the most extraordinary ideas about ozone—for instance, they would insist upon walking their friends along certain ridges by the seaside where brackish sea water was covered by a green slime, which gave a horrible smell, and this they said was ozone. Personally he did not believe it was; it was the dreadful smell that was usually associated with rotten eggs.

Lieutenant-Col. Sir Charles Bedford, I.M.S., said that the authors had referred to the question of the smallest proportion of ozone which was perceptible to the senses. Hartley found that $\frac{1}{500000}$th part of ozone was perceptible to the senses. The ordinary proportion of ozone in air was something like $\frac{1}{1000000}$th of the volume of air, and it had been found that $\frac{1}{1100}$th to $\frac{1}{1200}$th of a milligram of ozone per litre constituted, for certain therapeutic purposes, an innocuous dose.

Dr. Samuel Rideal said that the authors had dealt with the theory of ventilation in a simple, straightforward manner that everyone could appreciate. It was now well known that the problem of ventilation was a question of temperature and moisture rather than of oxygen or carbonic acid. Personally, he would have been glad if the authors had given some further information with regard to the effect of ozone, if any, on the problems of ventilation. Although he had done work in connection with ozone in water, he had had no personal experience with regard to ozone in ventilation. One of the principal properties of ozone was its power as an oxidising agent; and one would think probably that the disappearance of smell when ozone was used in ventilation was its oxidising effect upon small quantities of volatile or organic matter, which seemed to be the things that caused the smell; and that oxidising effect was more rapid when ozone was present than the small oxidising effect that took place by natural oxygen. But, in addition to that point, it would have been of interest if the authors had referred to the effect of ozone on the germs which he had indicated were the things which might be present in the air of a room that might have injurious effect upon health. The authors had not, however, given any information whatever with regard to the germicidal effect of small quantities of ozone on any stray pathogenic organisms that might be present in the air of a tube or a room after someone had been sneezing, coughing, or talking. He had been in some buildings where ozone had been used for ventilation—the Lord Chief Justice's Court, for example—where he knew that unpleasant smells previously existed, and he was able to confirm what had been said with regard to the distinct improvement in the smell of a place which had been ventilated by means of ozone or ozonised air. But it was necessary to be very careful in dogmatising upon its effect, because in those places where ozone ventilation had been introduced the method adopted had had a double effect, the ventilation itself having been changed in addition to the introduction of ozone. It was very difficult to tell under those circumstances how much of the improvement was due to the modification of the ventilation *per se* without the ozone, and how much was due to the additional effect of the ozone in changing the ventilation. As the authors had pointed out, lack of uniformity was essential to comfort, and such

Hosted by Google

changes in the quality of the air could be brought about by ordinary ventilation, by bringing in the fresh air in gusts, or by means of puffs from an organ outside. It would, therefore, be interesting to know how much of the improvement in the places referred to was due to the ozone, and how much to the change of the method of ventilation.

Mr. Edward L. Joseph said that, so far as his own experiments had gone, they went to prove the absolute falsity of the figures given by Sir Charles Bedford with regard to the percentage of ozone in the air. From the figures given it would appear that on the average there were ten parts in a million of ozone in the atmosphere, but, personally, he thought it would be more correct to say there was only one part in a thousand million present. In reply to Dr. Rideal's remarks, he wished to say that a test was invariably made in all the installations of ventilation, both with and without the ozone, and it was easy to gauge the effects. Some very striking examples of the improvement in ventilation due to the use of ozone had come within his own personal knowledge in hide and skin warehouses, and other places where unpleasant occupations were carried on.

Dr. Martin Flack confirmed Mr. Joseph's remarks with regard to the absolute absurdity of the figures given by Hartley. Experiments had been carried out on some rats in a glass bell-jar into which ozone in a concentration of one per million had been injected; while in another bell-jar by the side rats were placed, and no ozone was injected but simply the air from a fan. The temperatures of the animals were taken before the experiment, and it was noticed that when the ozone was turned on that their metabolism was depressed, while at the end of a certain number of minutes their temperature had fallen. In the meantime the animals put up their fur, kept very still, and showed every sign of discomfort. He knew from his own experiments that Hartley's figures were altogether wrong, and the figure Mr. Joseph had given was probably correct. With regard to the question of uniformity, it was possible in a system of ventilation to turn the ozone on and off, and thus obtain that lack of uniformity which was so essential to good ventilation.

Mr. F. W. Jennings thought the authors had not laid sufficient emphasis on the connection between heating and ventilation. It had always been considered by ventilating engineers that the ventilation of a building could not be satisfactorily dealt with unless the heating was considered at the same time. The authors had not said very much on that question, although they mentioned that the most satisfactory rooms from the heating and ventilating point of view were those dealt with by open fires. He quite agreed in that remark, but, unfortunately, open fires were not applicable to many rooms. The most satisfactory rooms with artificial central heating that he had seen were in some schools that had recently been built in Staffordshire, which were arranged with open windows on two sides, but with an abnormally large amount of heating surface for the radiators; in fact the system appeared to be that the rooms were made so exceedingly hot that it was necessary to have the windows open. In such rooms as assembly halls, very satisfactory results had been obtained by keeping the temperature of the heating surface down. Some of the best installations he had seen were in cases where the rooms had been heated by direct heating radiators independently of the ventilation, a small amount of heat being added to the air to bring it to approximately the same temperature as the room. Consequently the temperature of the air in the room could be varied independently of the heat of the room itself. The air was passed over steam coils at an exceedingly low temperature, the temperature of the heated surface not exceeding 180 degrees. That system appeared to prevent a great deal of the unpleasant dryness or scorching of the atmosphere. Both the temperature and the humidity were automatically controlled. That system was very satisfactory for assembly halls in which the people stayed for only a comparatively short period of time, but he had not yet discovered any really satisfactory system of mechanical ventilation for rooms such as offices in which the occupants stayed the whole day. He thought the authors had struck the right note when they pleaded for a change of uniformity. As a ventilating engineer he welcomed the paper very much indeed, because if such engineers were clearly told the requirements that scientific gentlemen insisted upon they would undertake to fulfil them. He did not think, however, that ozone was the only thing to be considered, because it would have been impossible to blow cold air into rooms during such weather as had recently been experienced; it was essential that the chill should be taken off it.

Mr. J. H. Vincent said the authors had pointed out the evil effects of highly moist atmosphere. It would be of interest, he thought, if the authors stated whether it was not advisable to prevent air from being supplied too dry.

Mr. E. P. Grove said the Central London Railway Company had realised that the air on the Tube was not exactly what it should be, and had, therefore, expended a very large sum in installing an ozone ventilating system, by means of which the quantity of air put into each station would ultimately be about 8,000 cubic feet per minute. The ozone portion of the system formed a distinct feature; but he had noticed that it was sometimes difficult to tell whether the ventilation plant was at work unless it was possible just to smell the ozone. He thought it was the general opinion that the air on the Central London Tube was greatly improved; in fact, he did not think it could be very much better on a tube railway, in

Hosted by Google

view of the particular conditions under which tube railways had to work.

MR. F. A. WILLCOX said that, as he had had some experience with carbonic acid and ozone, he fully appreciated the authors' remarks with regard to the effect of carbonic acid, and the quantities it was possible to breathe. He had worked on one of the carbonic acid collecting plants in the vats of a brewery, where, instead of the gas being put into the bottles, about 500 lbs. of the gas was being blown into the atmosphere per hour. He noticed that so long as he stood still there was no appreciable effect; but if he tried to run up a ladder, or go from one end of the room to the other, he got out of breath, just in the same way as he would do in making a hundred yards' sprint. He was rather disappointed that the authors had not given more information with regard to the germicidal effect that ozone had, because he gathered from the paper that the principal injurious agents in the atmosphere were the bacteria and the organic matters which were exhaled by human beings. If ozone had some effect in that direction it would probably be very advantageous. He desired to ask the authors also whether they were perfectly sure that the oxides of nitrogen were got rid of in the apparatus used. It was also well known that the unsaturated fats had a great affinity for ozone. He had noticed himself that a fairly concentrated atmosphere had an irritating effect on the skin; and it would be interesting to know if the authors had carried out any experiments in that direction.

DR. LEONARD HILL, in reply to the questions that had been asked with regard to ozone and germs, said that in weak concentrations such as it was possible for human beings to breathe without any injurious irritation to the respiratory tract, the ozone could not be expected to influence the germs. The germs, or bacteria, were structurally capable of much more resistance than a human being's sensitive mucous membrane. There was a great deal of error broadcast in the minds of some people, who thought it was possible to take into the lungs, or any part of the body, some kind of antiseptic solution which would kill a germ and not kill a human being. That was not the case. It would kill the human being much more readily than the germ. Concentrated ozone had been passed over the top of culture fluids without destroying organisms like the coli bacillus. He had no evidence on the point of whether it was possible to destroy organisms by very high concentrations. If all the air was passed through the ozoniser and went through the plates, he was not in a position to say how far that would sterilise it; the subject required careful bacteriological examination. With regard to the question of the oxides of nitrogen, many physiological tests were far more sensitive than chemical tests. Physiologists and bacteriologists dealt with solutions which could not be dealt with by the balance and chemical methods. He had demonstrated some things by biological tests which could not be detected at all by chemical tests. It was possible that, all the time, there were in the ozone traces of oxides of nitrogen, and that the irritating effects were due to that cause. He had not yet carried out the experiment of trying to get rid of the oxides of nitrogen, and the suggestion made by Mr. Willcox with regard to that matter was a very valuable one. In reply to Mr. Vincent's question, the air could be made too dry, and it was then just as bad as being too moist. During the excessively cold weather in America the air was heated to 100° F., or 120° F., and then driven into the schools. The air outside might be saturated with moisture to 20° below zero, but when it was heated up to 120° F. it was nothing but dry, desert air, which wetted itself against the bodies of the children, took all the moisture out of their skins, lessened their vigour, lessened their immunity to diseases, and made them very miserable. He believed very dry air was the worst thing possible for respiratory diseases. So far as the Central London Tube was concerned, he thought its ventilation had been very greatly improved by the introduction of ozone. The smell was very much less, the air was pleasanter in every way, and the old uniformity had been changed. He thought the right plan to adopt was for the ozone to be just perceptible to the smell. He quite agreed with the speaker who mentioned that there was no better method of ventilation than that adopted in the Staffordshire schools, where there was plenty of radiant heat and open windows. The ideal method to aim at was to get the cool air from outside, and to have radiant heat.

THE CHAIRMAN, in proposing a cordial vote of thanks to the authors for their interesting paper, said there was one thing they drew attention to which ought to be borne in mind, namely, that the law of nature was infinite variety, and that the bane of most human systems was the attempt to obtain uniformity in circumstances which were not uniform. Although he was not an anti-vivisectionist or a vegetarian, he thought thanks should be accorded to the authors also for the flourishing condition of health their guinea-pigs exhibited, in spite of their experiments; in fact they were so humane that they did not even kill fleas.

The resolution of thanks having been carried unanimously, the meeting terminated.

CORRESPONDENCE.

RADIO-TELEGRAPHY.

I fully agree with the remarks made by Professor G. W. Osborn Howe, following on his valuable paper, in regard to the strategic aspect of wireless telegraphy, and, as evidence of the same conclusions

Hosted by Google

being arrived at by myself independently, I should like to quote the following from my article on "Telegraphic Communications and the Empire," published in the *Empire Review* last December :—

"Let us now consider the services which wireless telegraphy can perform in the interests of the British Empire. This branch of applied science has developed in an altogether wonderful way; and, thanks largely to the business ability and enterprise of Mr. Marconi and his companies, it has already achieved much. It is some years ago now since I urged for wireless telegraphy being turned to account—on trial at any rate—as an auxiliary to cables throughout the Empire, whilst also pointing to its application for coast communication and general maritime uses. Since then, Mr. Marconi, by dint of enormous perseverance in various directions, has established a regular trans-Atlantic wireless service. Here he has been brought into competition with rival cable companies affording an excellent service of long standing; and if a comparison be made between the trans-Atlantic cable service and the trans-Atlantic wireless service it cannot at present be claimed that the latter seriously approaches the former in point of efficiency, though having the advantage in the matter of cost.* It only remains to be said the wireless system has so far been materially handicapped by the fact that, unlike the cable services, it has not had satisfactory land-line connecting links on the other side. But whilst this accounts for the comparatively small number of trans-Atlantic messages sent by the wireless system, and also, to some extent, for the comparatively long time occupied by those which are sent, it does not serve as an explanation for those radio-telegrams which never reach at all or for the errors on others . . . ."

"Apart from the superiority of the cable service in accuracy, speed and even certainty of reception, it has a distinct advantage over the wireless system —amongst those that know both—as a stragetic asset. Wireless telegraphy is of considerable value to the Navy—as well as generally—in times of peace, when the operators on seeing a message is not for them leave it alone; but that sort of consideration for others, and the property of others, would scarcely prevail if trouble were in the wind or when actual war was proceeding. Under such conditions everyone would be picking up everybody else's messages and making what could be made of them, besides disturbing them where possible. In this way, wireless telegraphy would be likely to prove a two-edged weapon, indeed. Another point that requires consideration is the fact that all wireless stations having masts and aerials—more or less high—form a handy target for the enemy. Whatever provision may be made to meet this objection, it cannot be gainsaid that a wireless station is liable to be a far more vulnerable object than a deep-sea cable. Then again, whilst radio-telegraphy can be carried on fairly satisfactorily in temperate zones, that is not so in the tropics, and 'atmospherics' are, as yet, always a source of more or less trouble, often stopping operations for several hours on end. These are, indeed, serious objections to the movements of a fleet being directed from headquarters by 'wireless'—especially where a number of re-transmissions have to be accomplished. Further, we may have to battle with the demoralising influence of any untuned system—such as that on the Eiffel Tower—within, say, a range of 1,000 miles."

Caxton House, Westminster. CHARLES BRIGHT.

* On this account it should serve as a lever for bringing down cable rates.

ILLUMINATED MANUSCRIPTS.

I read with the greatest interest Mr. Davenport's paper on "Illuminated Manuscripts," and the discussion which followed. I hope it will not be deemed presumptuous of me if I venture to differ from Sir William Armstrong in his remarks as to the ease of carrying out interlacements in metalwork correctly. In my experience, as long as the pattern simply consists of plaitwork, or the interweaving of several strands with free ends, wirework is fairly plain sailing; but when a single strand has to be doubled and interlaced on itself it is quite a different matter, and a long time may sometimes be spent in arranging the proper alternating "overs" and "unders" if the design is at all elaborate.

I speak from practical experience, having long been enamoured of Celtic metalwork, and having carried out many pieces of jewellery in which interlaced wirework has been a prominent feature. I have, however, never succeeded in attaining anything remotely approaching the almost incredible intricacy of some of the Celtic interlacements. I *may* some day, but in the meanwhile I find it sadly easy to "go wrong" in the attempt. It is very interesting to try to carry out some of the patterns on a large scale with the soft lead wire used for horticultural purposes. It is very pliable and, if not often bent too sharply, does not break easily. But even with this soft material, and on a scale so much larger than the original, the attempt to follow out even a fairly simple pattern is apt to make me feel very humble when I compare the often "worried looking" result with the straightforward achievements of the old-time craftsmen.

I do not know how hard it may be to keep an interlaced pattern right in an illumination. I have never tried. But I am quite convinced that it is very far from "difficult to make it wrong in metalwork." MACIVER PERCIVAL.

THE OLD DISTRICT RECORDS OF BENGAL.

Mr. Firminger's paper, published in the *Journal* of the 2nd inst., has aroused widespread interest in the old Bengal records. These are of the utmost importance. May I be permitted to suggest that

Hosted by Google

one of the many Government offices, which, under the new arrangements consequent on the change of capital to Delhi, will be vacated in Calcutta, should be used as a central Bengal Record Room for all records of the Province older than 1793, the date most approximately marking the end of the heroic period of revenue administration in Bengal? This bringing together of the now scattered relics of the olden days, in what must still and always remain "the premier city," would be a most desirable step in the direction desired by Sir Steuart Colvin Bayley and other speakers, of assuring their future security and accessibility to students and historians for research purposes.

Failing Calcutta, to my mind Whitehall should house all these documents, rather than they should be left to their present unsatisfactory chances of permanent preservation.

WILMOT CORFIELD.

OBITUARY.

HENRY TAYLOR BOVEY, M.A., LL.D., D.C.L., F.R.S.—Dr. Henry Taylor Bovey, formerly Rector of the Imperial College of Science and Technology, South Kensington, died at his residence in Eastbourne on the 1st inst.

Dr. Bovey was born at Torquay in 1852. After being educated at a private school he proceeded to Queens' College, Cambridge, and graduated as Twelfth Wrangler in the Mathematical Tripos in 1873. He was shortly afterwards elected a Fellow of his College. Adopting the profession of a civil engineer, he joined the staff of the Mersey Docks and Harbour Works, of which he was soon appointed assistant engineer. In 1887 he went to Canada, on his appointment to the Chair of Civil Engineering and Applied Mechanics at McGill University, Montreal. At this time the engineering courses of the university were managed as a branch of the Faculty of Arts, and it was mainly owing to Dr. Bovey's advice and energy that a new department of Applied Science was created, which has developed into one of the most important and successful branches of the university.

In May, 1909, Dr. Bovey was recalled to this country, having been appointed the first Rector of the Imperial College of Science and Technology, but, unfortunately, his health broke down, and he was compelled to resign in the following December.

Dr. Bovey was LL.D. of McGill and Queen's Universities, and D.C.L. of Lennoxville. He founded the Liverpool Society of Civil Engineers, and was one of the founders of the Canadian Society of Civil Engineers, an honorary member of the National Electric Light Association of the United States, and a Fellow of the Royal Society of Canada. In 1897 he was Vice-President of the Mechanical Section of the British Association, in 1902 he was elected F.R.S., and in 1906 his old college at Cambridge made him an honorary Fellow.

Dr. Bovey joined the Royal Society of Arts in 1907. Two years later he was elected on to the Council, on which he continued to serve up to the time of his death.

NOTES ON BOOKS.

SHOULD WE STOP TEACHING ART? By C. R. Ashbee. London: B. T. Batsford. 3*s*. 6*d*. net.

The place of art in the modern industrial system, and public art education generally, are questions which have been before us of late years in one or other of their aspects; and at a time when the Royal College of Art and the art schools throughout the country are the subject of inquiry and report by a departmental committee, Mr. Ashbee's critical examination of the present system of art teaching, and his practical proposals for its reconstruction so that art can take its proper place under modern economic conditions, are both interesting and suggestive.

No one who has once grasped the sad significance of the Royal College statistics as presented in the committee's report, can pretend that the present method of fostering art by scholarships and endowments is at all satisfactory. In a period of ten years 429 students were trained at the Royal College; of these only thirty-two have made the practice of art in any form their livelihood, while 126 earn their living as teachers. In view of these figures, Mr. Ashbee's titular question can hardly be answered offhand, unless in the affirmative. In short, the supply of trained art-workers has far outrun the demand, for the public, if it wants their work at all, only wants it for a price at which they cannot produce it and live; so that at present it is only at the expense of the artist that we can make good works of industrial art accessible to the average man. Mr. Ashbee cites newspaper illustration among the few cases—such as architecture, etc.—in which economic independence has not been undermined by machinery; but surely even here photography threatens the artist's pen.

If we want the arts, then, we must somehow enable them to meet the conditions of our time, make it possible for them to compete against the machine, and protect them against its unfair competition. These things Mr. Ashbee would do by a sort of art bounty, by starving out machinery, when wrongly applied, by means of a State subsidy to good work. Much of the money now spent in futile teaching he would like to see spent in the endowment of artistic workshops, where apprentices might learn their craft, and he rightly urges that by so doing we should "endow skill, invention and imagination," instead of as at present stimulating them artificially in schools and then checking them unnaturally in life. After a detailed consideration of the various educational, agricultural, and other issues involved by his proposed reforms, Mr. Ashbee comes to the constructive aspect of

Hosted by Google

his subject, and outlines his scheme for the transformation of the art school system of the country into a guild system of associated workshops. His wide and varied experience—artistic, educational, administrative and architectural—ought at least to secure for his views the careful consideration of the authorities.

GENERAL NOTES.

THE VINTAGE OF 1911 IN FRANCE.—The *Moniteur Vinicole* states that the result of vintage in France during 1911 shows a great improvement on that of 1910, which was an exceptionally bad one. It estimates the total production of wine of Continental France, the island of Corsica, and the colony of Algeria, in 1911, as compared with the previous year, to be as follows:—

	1910. Hectolitres.	1910. Gallons.
France . . .	28,529,964	627,659,208
Corsica . . .	143,086	3,147,892
Algeria . . .	8,414,654	185,122,388
Total . .	37,087,704	859,929,488

	1911. Hectolitres.	1911. Gallons.
France . . .	46,776,000	1,029,072,000
Corsica . . .	160,000	3,520,000
Algeria . . .	8,500,000	187,000,000
Total . .	55,436,000	1,219,592,000

THE EXPORT OF EGGS FROM EGYPT.—Hens' eggs are now exported in considerable quantities from Egypt during the winter months—that is to say, from November to March. They are shipped principally at Alexandria. During last winter no fewer than 83,608,000 eggs, to the value of £125,000 sterling, were exported. Of this number, 74,000,000 were sent to England, 3,037,000 to France, and the remainder to other countries. The eggs are comparatively small in size, but the prices are proportionately low.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock:—

FEBRUARY 14.—CECIL THOMAS, "Gem Engraving." SIR ARTHUR JOHN EVANS, D.Litt., LL.D., F.R.S., will preside.

FEBRUARY 21.—FRANK WARNER, "The British Silk Industry and its Development since 1903." SIR GEORGE BIRDWOOD, K.C.I.E., C.S.I., M.D., LL.D., will preside.

FEBRUARY 28.—H. A. ROBERTS, M.A., Secretary of the Cambridge University Appointments Board, "Education in Science as a Preparation for Industrial Work." PRINCIPAL SIR HENRY A. MIERS, M.A., D.Sc., F.R.S., will preside.

MARCH 6.—T. THORNE BAKER, "Some Modern Problems of Illumination: The Measurement and Comparison of Light Sources."

MARCH 13.—PROFESSOR ERNEST A. GARDNER, M.A., "Greek Sculpture."

MARCH 20.—F. MARTIN DUNCAN, "The Work of the Marine Biological Association."

MARCH 27.—THEODORE E. SALVESEN, "The Whaling Industry of To-day."

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

APRIL 25.—WALTER SAISE, D.Sc., M.Inst.C.E., Hon. Member Institute of Mining and Geology, India, A.R.S.M., V.D., "The Coal Industry and Colliery Population of Bengal."

MAY 16.—NEVILLE PRIESTLEY, Managing Director, South Indian Railway, "Indian Railways."

COLONIAL SECTION.

Tuesday afternoons, at 4.30 o'clock:—

MAY 7.—ALAN BURGOYNE, M.P., "Colonial Vine Culture."

MAY 21.—THE HON. J. G. JENKINS, "Australian Railways."

CANTOR LECTURES.

Monday evenings, at 8 o'clock:—

LOUDON M. DOUGLAS, F.R.S.E., "The Meat Industry." Three Lectures.

Syllabus.

LECTURE II.—FEBRUARY 12.—The Sheep and its Products.

LECTURE III.—FEBRUARY 19.—The Pig and its Products.

LUTHER HOOPER, "The Loom and Spindle: Past, Present, and Future." Three Lectures.

February 26, March 4, 11.

NOEL HEATON, B.Sc., F.C.S., "Materials and Methods of Decorative Painting." Three Lectures.

March 18, 25, April 1.

HOWARD LECTURES.

Monday evenings, at 8 o'clock:—

CAPTAIN H. R. SANKEY, R.E., M.Inst.C.E., "Heavy Oil Engines." Four Lectures.

April 29, May 6, 13, 20.

Dates to be hereafter announced:—

CHARLES C. ALLOM, "The Development of Artistic Skill in the Applied Arts."

ERNEST KILBURN SCOTT, Assoc.M.Inst.C.E., M.I.E.E., "The Manufacture of Nitrates from the Atmosphere."

Hosted by Google

Charles Bright, F.R.S.E., M.Inst.C.E., M.I.E.E., "The Administration of Imperial Telegraphs."

Harold Cox, "The Interdependence of Morals and Economics."

E. D. Morel, "British Rule in Nigeria."

Gordon Craig, "Art of the Theatre." Miss Ellen Terry will preside.

George Fletcher, "Technical Education in Ireland."

MEETINGS FOR THE ENSUING WEEK.

Monday, February 12...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Mr. Loudon M. Douglas, "The Meat Industry." (Lecture II.—The Sheep and its Products.)

Royal National Pension Fund for Nurses, at the Royal Society of Arts, John-street, Adelphi, W.C., 3.30 p.m.

Post Office Electrical Engineers, Institution of, at the Institution of Electrical Engineers, Victoria-embankment, W.C., 5 p.m. Mr. A. W. Martin, "Economics of Telephone Transmission."

Brewing, Institute of (London Section), Criterion Restaurant, Piccadilly, W., 8 p.m. Mr. Arthur R. Ling, "Malting." (Part II.)

Sanitary Engineers, Institute of, at the Royal United Service Institution, Whitehall, S.W., 8 p.m. Messrs. Albion H. Scott and F. C. Davies, "Hospitals and Sanitoria and their Relations to Tuberculosis."

Mechanical Engineers, Storey's-gate, Westminster, S.W., 8 p.m. (Graduates' Lecture.) Dr. T. E. Stanton, "Recent Researches at tne National Physical Laboratory."

Architectural Association, 18, Tufton-street, S.W., 7.30 p.m. Mr. P. Waterhouse, "Bridges."

Tuesday, February 13...Sociological, at the Royal Society of Arts, John-street, Adelphi, W.C., 5.15 p.m. Dr. C. W. Saleeby, "National Eugenics and National Insurance."

Moral Education League, at the Royal Society of Arts, John-street, Adelphi, W.C., 8 p.m.

Asiatic, 22, Albemarle-street, W., 4 p.m. Sir Charles Eliot, "The History and Monuments of Cambodja."

Royal Institution, Albemarle-street, W., 3 p.m. Professor W. Bateson, "The Study of Genetics." (Lecture V.)

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Discussion on papers by Mr. D. C. Leitch, "The Water-Supply of the Witwatersrand"; and by Mr. E. C. Bartlett, "Investigations relating to the yield of a Catchment-Area in Cape Colony."

Photographic, 35, Russell-square, W.C., 8 p.m. Annual General Meeting.

Colonial, Whitehall Rooms, Whitehall-place, S.W., 8.30 p.m. Lieutenant-Colonel J. H. Patterson, "Travel and Sport in East Africa."

Horticultural, Vincent-square, Westminster, S.W., 2.30 p.m. Annual General Meeting.

Pharmaceutical, 17, Bloomsbury-square, W.C., 8 p.m. Professor H. G. Greenish and Miss Dorothy J. Bartlett, "The Powdered Gentian, Nux Vomica, and Ipecacuanha of Commerce."

Wednesday, February 14...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. Cecil Thomas, "Gem Engraving."

Biblical Archæology, 37, Great Russell-street, W.C., 4.30 p.m. Mr. H. R. Hall, "An Archæological Journey in Crete."

Automobile Engineers, at the Institution of Mechanical Engineers, Storey's-gate, Westminster, S.W., 8 p.m. Mr. G. F. Barrett, "Causes of Failure in Ball Bearings."

Japan Society, 20, Hanover-square, W., 8.30 p.m. Mr. S. Dick, "The Kano School of Painting."

Royal Society of Literature, 20, Hanover-square, W., 5.15 p.m. Professor M. A. Gerothwohl, "Alfred de Vigny and his Relation to English Pessimists."

King's College, Strand, W.C., 5 p.m. (Lectures on Christian Art.) Professor W. R. Lethaby, "The Classic Age of Byzantine Art and the Architecture of Justinian."

St. Paul's Ecclesiological Society, Chapter House, St. Paul's, E.C., 8 p.m. Mr. P. H. Hepburn, "Romanesque Churches of France." (Part II.)

Thursday, February 15...Cyclists' Touring Club, Metropolitan District Association, at the Royal Society of Arts, John-street, Adelphi, W.C., 8 p.m. Mr. A. C. Mylam, "The Ups and Downs of Five M.D.A. Members in the West Country."

Royal, Burlington House, W., 4.30 p.m.

Antiquaries, Burlington House, W., 8.30 p.m.

Linnean, Burlington House, W., 8 p.m. 1. Mr. R. H. Compton, "An Investigation of the Seedling Structure in the Leguminosæ." 2. Mr. C. E. Salmon, "An Abnormal Orchis from the Surrey Downs." 3. Mr. H. Findon, "Sponges from Japan."

Child Study, 90, Buckingham Palace-road, S.W., 7.30 p.m. Captain A. St. John, "Control during Adolescence."

Chemical, Burlington House, W., 8.30 p.m. 1. Messrs. F. B. Power and H. Rogerson, "Chemical Examination of Scammony Root and of Scammony." 2. Messrs. A. McKenzie and G. W. Clough, "Experiments on the Walden Inversion. Part VIII.—*a*-Amino-*a*-phenylpropionic Acids." 3. Mr. P. Neogi, "Preparation of the Nitrites of the Primary, Secondary and Tertiary Amines by the Distillation and Sublimation in a Vacuum of Concentrated Solutions of Mixtures of the Hydrochlorides of the Bases and Alkali Nitrites." (Part I.) 4. Messrs. P. C. Ray, J. N. Rakshit and R. L. Datta, "Nitrites of the Mercurialkyl- and Mercurialkylarylammonium Series." 5. Messrs. P. C. Ray and J. N. Rakshit, "Nitrites of the Alkylammonium Series. Part IV. — Isobutylammonium Nitrite, Diethylammonium Nitrite, Dipropylammonium Nitrite, and Tripropylammonium Nitrite, and their Decomposition and Sublimation by Heat." 6. Messrs. M. O. Forster and J. H. Schaeppi, "Perhalides of Diphenyliodonium Iodide."

Royal Institution, Albemarle-street, W., 3 p.m. Mr. M. H. Spielmann, "The Portraiture of Shakespeare." (Lecture I.)

Journal of the Royal Society of Arts.

No. 3,091. VOL. LX.

FRIDAY, FEBRUARY 16, 1912.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, FEBRUARY 19th, 8 p.m. (Cantor Lecture.) LOUDON M. DOUGLAS, F.R.S.E., "The Meat Industry." (Lecture III.)

WEDNESDAY, FEBRUARY 21st, 8 p.m. (Ordinary Meeting.) FRANK WARNER, "The British Silk Industry and its Development since 1903." SIR GEORGE BIRDWOOD, K.C.I.E., C.S.I., M.D., LL.D., will preside.

Further details of the Society's meetings will be found at the end of this number.

CANTOR LECTURE.

On Monday evening, February 12th, MR. LOUDON M. DOUGLAS, F.R.S.E., delivered the second lecture of his course on "The Meat Industry."

The lectures will be published in the *Journal* during the summer recess.

EXAMINATIONS.

The Council of the Society are much gratified at being able to announce that the London County Council Education Committee have consented to undertake, this year and in the future, the entire supervision of the Society's Examinations in the County of London. This will involve certain modifications in the usual arrangements, and some concentration of the smaller centres.

The forms of application for examination papers, together with the fees, must be returned to the London County Council Education Office not later than February 20th. Shortly after the forms have been received by the Council, tickets for all candidates, showing where they are to sit for examination, will be sent to each centre. The Council will arrange, as far as possible, for the candidates from all large centres to be examined at those centres. The smaller centres will be grouped together at convenient places. The examination papers will be sent to the Council offices, and the Council will make all the arrangements for the superintendence of the examinations. In printing the results, every centre, as now, will have the credit of all certificates gained by its candidates.

It is expected that the proposed arrangement will greatly enhance the value of the Society's certificates, and will facilitate the conduct of the examinations. Some additional cost will be involved, but for the present year this will be borne by the Society. It is probable that in future years a moderate subscription may be required from the local committees, to cover the cost of supervision.

PROCEEDINGS OF THE SOCIETY.

TENTH ORDINARY MEETING.

Wednesday, February 14th, 1912; SIR ARTHUR J. EVANS, M.A., D.Litt., LL.D., F.R.S., in the chair.

The following candidates were proposed for election as members of the Society:—

Brown, Frank Percival, A.R.C.A., Halford House, Richmond, Surrey.

Buckley, John, "Arncliffe," Chartfield-avenue, Putney, S.W.

Hayward, Miss Florence, 4937, McPherson-avenue, St. Louis, Missouri, U.S.A.

Higgs, Arthur King, 95, High-street, Cheltenham.

Jhalawar, His Highness the Raj Rana of (Sir Bhawani Singh, K.C.S.I.), Kothi-gardens, Jhalrapatan, Rajputana, India.

Wakefield, Captain Edward William, Strickland-gate House, Kendal, Westmoreland.

Hosted by Google

The following candidates were balloted for and duly elected members of the Society:—

Sacoom, Samuel, Axim, Gold Coast Colony, West Africa.

Wood, Sir Henry J., 4, Elsworthy-road, N.W.

The paper read was—

GEM ENGRAVING.

By Cecil Thomas.

Gem engraving is a subject of such great extent that it is necessary for me to select from a vast amount of interesting matter that which can be most suitably dealt with in a short paper, so, in accordance with my technical habits, I

Fig. 1.—Drilling a Seal by a Seal-maker.

(From the tomb of Thy at Sakkara.)

propose to deal with the technology of the art, illustrating the methods and work of the different periods. In order to avoid confusion in the use I make of the word "gem," I should say that I refer to it in its original sense—viz., an engraved stone.

The engraving can either be incised into the stone, in intaglio, and so form a seal capable of taking impressions, or can be engraved in relief to make the familiar cameo; also larger objects—such as statuettes, vases and other sculptures—can be produced by the engraver in precious stone.

The invention of gem engraving is coeval with the first dawn of civilisation, for whenever man emerged from the savage condition and realised his power of delineating line and form, then would he discover the all-important but childishly simple secret of the art of engraving gems—*i.e.*, that the many beautiful stones that lay around him, ready shaped by Nature, were easily scratched or engraved by sharp splinters of other and harder stones that in equal profusion lay ready to his hand. This rule that a hard stone will cut a softer one is the basis of the technique, the application of which has resulted in the beautiful productions for which the art is justly famous.

The earlier engravings are, therefore, on the softer varieties of stone, such as steatite, serpentine, limestone, lapis, etc., all of which can easily be engraved with a sharp splinter of flint, and we find gems engraved in this way in Egypt, Babylonia, and the Ægean Islands.

The seal form peculiar to the Babylonians, early Egyptians, and later the Assyrians, is the curious cylinder of stone having the device incised round the surface, so that when rolled on soft clay an impression in relief of the whole of the engraved surface is obtained. The engraved gems common to Egypt are in the form of scarabs—*i.e.*, the stones are carved to represent the venerated scarabaeus beetle, the flat underside of which has the device incised to form a seal. The important use of early scarabs was for funereal purposes, and they were also used as amulets.

The gems from the Ægean Islands are distinct from the Babylonian and Egyptian seals, being three and four-sided prisms, and pebbles of round and oval shape used as seals and amulets.

All the early examples show interesting points of difference in technique, but prove that the important implement used in their production was the sharp splinter of stone or chisel of metal; this stone point would invariably be a splinter of corundum or emery mounted on the end of a suitable handle and used like a chisel to incise the engraving.

We shall see that this tool was used, more or less, up to Roman times, when it was entirely superseded. I have revived this tool with the difference that I use a diamond point, and find it invaluable for engraving the delicate parts of a cameo, such as the eyes, hair, etc.

The characteristics of crude point work are exemplified in the early engravings on soft stones from Crete, where a stiffness in the lines is most noticeable, curves being broken by the straight chisel-like cuts of the tool, the V-shaped section of the cuts proving that the implement was clumsy and perhaps of metal.

All point engraving is not of this nature, for as technical skill advanced, amazingly minute

Hosted by Google

work was produced with its aid. The best way of proving whether a gem is cut with a point is to examine with a glass the termination of the fine strokes. These should be abrupt and as deep as, or deeper than, the rest of the stroke; this is especially noticeable in the work of later

FIG. 2.—CYLINDER SEAL OF DARIUS.
(Persian. 521–485 B.C.)

Babylonia and of Assyria. There is also a tendency for the stroke to spread at the ends, owing to the repeated slipping of the tool. These are important points to remember when I come to deal with the methods of the forgers of antiques.

An astonishing feature of these early gems is the successful way in which the engravers have essayed the difficult task of drilling.

The illustration of an Egyptian seal-maker (Fig. 1) shows one method of doing this, by rolling the drill, which has a piece of quartz or corundum at the end, in the hand; the operator, being comfortably seated, holds the drill in such a position that he can maintain considerable pressure. This method would probably be used only for the softer stones.

The first great advance in the method employed is attributed to the engravers of Babylonia about the middle of the third millennium B.C., a drill revolved by means of the bow being used to hollow out the big masses of the engraving. These tools, which I shall refer to as burr drills, required to be moistened with corundum powder and oil to give a cutting edge. They opened greater possibilities to the artists who used the hemispherical drill holes to great advantage, placing them in juxtaposition and connecting the forms with the corundum point already described.

This resulted in the boldly modelled engraving so characteristic of the Babylonian cylinder seals. Its use is also seen in the shallower Assyrian work of a later period (see Fig. 2).

The vigorous treatment seen in later Babylonian work points to the use of yet another tool, a variation of the last. This we term a disc, and its value was to make a longitudinal cut; it was not used to a great extent, probably owing to the difficulty of controlling it.

It is obvious that for cutting only on the edge of the disc with the aid of corundum powder some form of bearing is required. This may have been supplied by a hollow block of wood held in the hand as illustrated in the Egyptian wall painting, or an additional bearing held by the teeth may have been employed. This method has apparently been used, and would give great control over the tool.

The only other ancient tool of importance is the tubular drill, the use of which is principally confined to the series of gems from Crete, a series contemporary with the Babylonian and Egyptian engravings, yet somewhat distinct in technique.

The importance of these island gems cannot be overestimated, and we must be grateful for the invaluable researches of Sir Arthur Evans, to whom we are indebted for their discovery and the interesting matter in relation to them.

We can trace in these gems first the use of a pointed instrument for chiselling the device in the soft steatite so plentiful in the island (Fig. 3), then the use of the burr and tubular drills. Formed from a tube of metal, the edge only of which cut with the aid of corundum powder, and revolved quickly with the assistance of the bow, the function of this tubular drill was to engrave circles and parts of circles, which would vary in size according to the diameter of the tube. The portions of circles or crescents were obtained by slanting the drill so that only a part of the edge cut the stone.

FIG. 3.—STEATITE.
(Three-sided seal. Crete. Before 2200 B.C.
In Sir Arthur J. Evans's collection.)

The results of its use are clearly seen in these examples, for which I am indebted to our Chairman, and the precision and delicacy of some of the engravings show advanced technical ability.

Hosted by Google

As you see in the illustration (Fig. 4), there is little difficulty in picking out the cuts of the various tools. The mechanical precision of the circles is the essential feature of tube-drill engraving, a result that cannot be obtained by other means. At first this tool was used somewhat crudely, but in later times—*i.e.*, during the period of greatest Minoan development—extraordinary dexterity is shown in manipulating the drill. This is seen in the three-sided cornelian seal, beautifully engraved with Cretan hieroglyphics, in Sir Arthur J. Evans's collection (Fig. 5). The illustration shows that the eyes of the cat are formed by two circles most carefully worked into the modelling of the face. The engraving has been so carefully finished with the corundum point that the use of the drill is partly concealed. The earliest examples I have found of tube-drill work in Egypt belong to the Twelfth Dynasty,

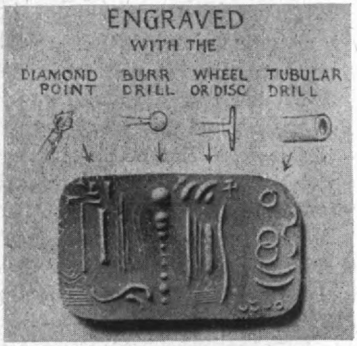

FIG. 4.—ENGRAVING TOOLS AND THEIR CUTS.

when it was used for drilling holes through quartz beads; this fact was conclusively proved to me by the splendid series of amethyst and cornelian beads arranged chronologically in the Ashmolean Museum. The larger stones were bored with this tubular drill whilst the solid or burr drill was used for smaller stones.

There are also examples of scarabs in the same museum cleverly engraved with arrangements of circles cut with the tube drill.

This tubular drill has been universally employed in the working of stone, and proves an efficient and valuable ally to overcome the most obdurate tasks. To illustrate this I might mention that, worked with the bow, it is the principal instrument used by the Chinese for their wonderful carving of jade; that it was known and used by the Aztecs for their mysterious and equally remarkable quartz carving, the remains amply testify; and, as is well known, the greatest glyptic monument—the St. Gothard tunnel, drilled through quartz—would have been impossible without its aid.

I might mention in this place that the Maories of New Zealand use a similar drill, but it consists

FIG. 5.—RED CORNELIAN.
(Three-sided bead seal. Crete. 1600 B.C.
In Sir Arthur J. Evans's collection.)

of a piece of quartz mounted on a shaft of wood and operated by the up-and-down movement of a transverse stick with a thong. The consequence is that their holes are very clumsy and irregular. Sand applied by the friction of a piece of wood is their principal agent in carving the material, not forgetting the valuable quality of patience: it often takes thirty years to produce one piece of work.

To proceed, we must consider the work of the early Greeks and the Etruscans, who, with their spirited drawing and clever handling of the technique brought the art to a higher level.

The illustration of a sard in the British Museum of Græco-Italian workmanship of the fifth century B.C., shows what is obviously an engraver using the bow-drill (Fig. 6). The engraving of this gem proves that the burr drill was still used with the aid of the bow as represented; but we see clearly, especially in the work of the following centuries, evidences of the use of a

FIG. 6.—GEM ENGRAVER USING THE BOW DRILL.
(Sard in the British Museum. Græco-Italian
work. Fifth century B.C.)

fine disc tool in the modelling of the figures. This freer use of the disc tool would necessitate some improved method of technique, and it is

Hosted by Google

quite possible that the first use of some form of lathe for engraving gems can be attributed to this period. This sard in the British Museum helps this theory; the raised position of the leg, apparently resting on a pivoted treadle connected with the projecting arm at the back, might give a thrusting movement to the bow if attached to the top of the arm, the bow working on the horizontal shaft of a drill, thus leaving both hands free for the engraving—a very essential point.

In the Greek engravings from the sixth century onwards, we see the finest examples of intaglio engraving possible, generally in low relief, on the different varieties of quartz. With their beautiful mythology to supply the motive and their wonderful power of sculpture, it is not surprising to find in their engraved gems a quality of beauty quite consistent with their statuary and coins; indeed, from the similarity of the engraving of the intaglio on stone and metal, we can presume that one artist would be responsible for both, as has, indeed, been the case ever since.

The most important feature in this period, one that worked a revolution in the art of engraved gems, was the discovery, presumably in the fifth century, of the value of the onyx, from which to engrave cameos. The onyx is a species of agate having parallel layers of stone of different colours, enabling the artist to carve a design in relief in the upper layers, thus obtaining a strong contrast to the darker coloured layer beneath. Great possibilities were now open to the clever Greek artists to engrave reliefs in this remarkable product of Nature, and that full advantage was taken of the opportunity numbers of magnificent cameos remain to testify. Carvings in relief in precious stone are met with earlier than this period in Egypt throughout the Dynastic period, in the form of the scarabs I mentioned earlier in my paper, and this form was also used by the Phœnicians, Etruscans and Greeks, and undoubtedly suggested the idea to the later artists of carving reliefs in precious stone for purely decorative purposes.

Cameos in onyx are not of frequent occurrence till the first century B.C., when the Greek artists, who flocked to Rome, produced large numbers for the luxurious Romans. These Græco-Roman cameos often attained extraordinary size, considering the nature of the material. Vases and cups of onyx, agate, crystal, etc., were now produced in great profusion, many of them being beautifully carved, like the agate vase in the Waddesdon Bequest in the British Museum.

The most magnificent cameo in point of size is the Triumph of Germanicus, carved in an onyx of five layers, measuring 13 ins. by 11 ins.; it is easily the largest in the world, and, after a chequered history, is now in Paris. It demonstrates with what a cunning hand the artist has used the various layers of a very beautiful stone. Smaller but finer cameos are seen in the onyx carved with a similar subject in Vienna; in the dignified head of Augustus in the British Museum, engraved in a stone of very pure colour, and in the very beautifully carved head of Medusa in Sir Arthur Evans's collection.

These beautiful specimens of the glyptic art convince us that the appliances used by the Græco-Roman artists had great cutting power, and it is apparent that revolving discs and burrs were principally responsible for the engraving.

FIG. 7.—THE ANNUNCIATION OF THE VIRGIN.

(Three-strata onyx cameo from the French collection. Tenth century. Byzantine.)

Although no actual representation exists of an engraver of the first century, it is generally agreed that the lathe was used to revolve the tools; certainly the nature of their work would necessitate some such apparatus. This implies that the tools used to-day by gem engravers are very similar to the simple instruments of the engravers of the Græco-Roman school—*i.e.*, a shaft or spindle, having a disc at the end would be placed horizontally on two bearings and revolved by means of a wheel below, the edge of the disc cutting with the aid of diamond or emery powder, when the stone is placed against it.

This, then, is the simple instrument that produced the masterpieces from the time of Alexander in the fourth century B.C., and which has been used in various forms ever since. It is important to add, however, that the diamond

Hosted by Google

point was the important agent with which the Greek artist finished his work.

In some engravings, particularly the earlier Greek intaglios, the whole of the detail, such as drapery, hair, etc., appears to be incised by this means, and it is distinguished by a freedom of drawing almost approaching sketchiness, that cannot be expressed by any other tools. In the first century A.D., the point seems to have been entirely superseded, if we can judge by one authentic specimen—an intaglio engraved with the head of Pallas Athene by Eutyches, one of the clever sons of Dioskorides. From a long and careful examination of this piece, I have come to the conclusion that the disc and burr tools were entirely responsible for the engraving; a use of the point is seen, however, in some Græco-Roman gems.

The Romans did not distinguish themselves as gem engravers, all the fine engravings of this period having been executed by Greek artists who, in company with the masters of other branches of art and literature, flocked to the hub of the Roman Empire. Thus, with the decline of art that set in about 300 A.D., we find the beautiful cameos and intaglios of earlier days replaced by work of a mediocre kind. The departed glories of Dioskorides, Felix, and Evodus are but faintly reflected in the poor Roman craftsmen who coarsely cut motto cameos and other insignificant work. Soon we lose the art altogether in the West, but see it continued in Byzantium, and further east in Persia.

From the fourth century onwards the strong influence of Christianity is seen in the Byzantine cameos and intaglios; engravers would often alter or add to an antique gem, having a representation from the Greek mythology, thus making it represent a scene from the life of Christ.

In Persia, under the influence of the Sassanian kings, fine stones were coarsely engraved with the portraits of the various monarchs, hunting scenes, animals, lettering, and monograms. These Sassanian gems add one point of value to a technical consideration of the art—*i.e.*, you are able to see clearly the style of crude disc tool work, of which they are mainly composed, and compare it with the early engraving of the diamond point, thus distinctly noticing the points of difference.

Poor workmanship and tasteless drawing are the characteristics of Byzantine gems, the only redeeming feature being a certain decorative filling of the space.

From the sixth century to the dawn of the fifteenth is a blank in the history of the glyptic art, with only a short revival about the tenth century, when cameos and intaglios with religious scenes were roughly engraved—as witness the three-strata cameo of the Annunciation in the French collection (Fig. 7), and in the British Museum the large intaglio of the Crucifixion in crystal, once belonging to Lotharius.

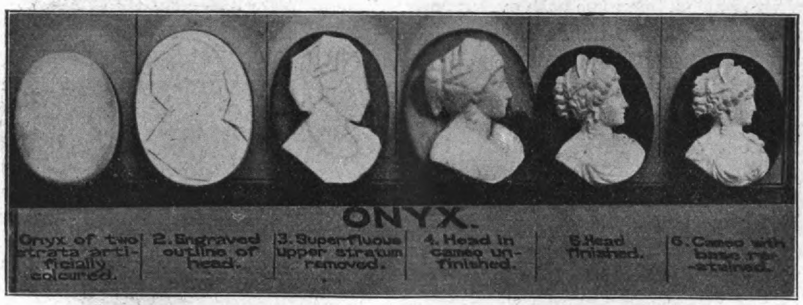

FIG. 8.—THE EVOLUTION OF THE CAMEO.

In the fourteenth century the art was reintroduced into Italy, and before the fifteenth century was far advanced was revived artistically and technically to an amazing degree. Though the designs engraved on gems during the revival followed closely the antique style, yet they fail to achieve the grand and dignified manner of the Greek engravings, or to approach them in the matter of large and magnificent pieces. It is true some artists of this period copied the antique so closely that it is not easy to distinguish the difference. It is consequently difficult to give rules to differentiate between antique and Renaissance gems. Undoubtedly the greatest asset is a knowledge of the styles of art of the different periods, as it enables you to detect the imprint and evidence that every gem must bear of the hand that engraved it. A knowledge of the technique is essential, so as far

Hosted by Google

as possible I will endeavour to show a few points of difference between ancient and modern engravings.

In modern cameo work a large thin disc, known as a slitter, is employed to remove the bulk of the stone by first cutting vertically and then horizontally; by continuing this process all round, only the mass of the stone required for the design is left (Fig. 8). This results in the large border of background characteristic of modern cameo engraving. There is no evidence of the use of such a tool for cameo engraving in Græco-Roman times, so we find their designs fill the whole space of the stone, a necessity enforced by the laborious method of grinding the stone away with burr tools.

An important difference between the backgrounds of antique and modern cameos is also noticeable, in that the former have an undulating surface, whereas the modern, owing to the advanced technical methods, are perfectly level. This is seen to perfection in the bust of Juno in the Paris Museum (Fig. 9).

It is generally supposed that high polish in the engraving of a cameo or intaglio is a sign of antiquity; this, however, is not so, as the modern artists can polish their work equally well. There is, however, a point of difference; the ancient artists largely used corundum, or emery, which during the process of engraving wears fine and so produces a cut with a dull polish. The modern engraver using diamond dust with an iron tool has to revert to the ancient practice in order to polish the engraving, with the result that unless it is done with great care, the minute cuts will be left rough. This is consequently a characteristic of many forgeries, that some parts are quite rough, whereas other parts have a very shiny polish. Other characteristics of modern work are the protuberance of the relief and the undercutting of some parts of the design, while antique work is generally flat and simple in relief, the edges being cut down vertically. Cameos of Roman origin, however, are bold in relief.

It has been said that it is impossible to identify a clever imitation of an antique, and this is to some extent true, so skilfully have the forgers copied the antique method and produced the ravages of time with cunning artifices. We must, therefore, rely on a knowledge of the styles of art and the subtle differences of technique.

FIG 9.—BUST OF JUNO.
(Three-strata onyx cameo. Good sixteenth century work in the French collection.)

FIG. 10.—QUEEN ELIZABETH.
(Cameo in three-strata onyx. Sixteenth century. French work.)

Cameos were produced during the Cinque-Cento period in the greatest profusion, often crowded with detail amazingly minute. This is also a characteristic of their intaglios, as is well illustrated by the signet of Michael Angelo that has seventeen figures in the space of half-an-inch. Ornamental intaglios in large plaques of crystal were also a feature of the age. It is during the sixteenth century that we first meet with the art in this country, one Richard Astyl being noted as "King Henry the Eighth's graver of gems." He may have been responsible for the very beautiful cameo portrait of King Henry VIII. and his son Edward VI. in H.M. collection at Windsor. These Tudor cameos form a series unique in the decorative treatment of the various colours of the different strata of the stones, as is well seen in the beautiful cameo of Queen Elizabeth (Fig. 10), possibly engraved

Hosted by Google

by Jean de Fontenay, who was invited over from France to engrave cameo portraits of the Virgin Queen, that she might present them to her many admirers. Judging from the number of these cameo portraits, she had a numerous following.

They are many of various sizes, apparently from the same hand that engraved the example illustrated.

After the beautiful productions of the Cinque-Cento, a decline is noticeable, the engravings of the seventeenth century becoming coarse and uninteresting, and it was not till the eighteenth century that a marked improvement set in, fostering particularly the production of intaglios.

FIG. 11.—GROUP IN RED JASPER, IN THE LUXEMBOURG MUSEUM, PARIS. (By M. Tonnellier.)

During this century a great wave of glyptic enthusiasm spread over the country, and every individual who desired to be considered a person of taste in the arts found it necessary to have a knowledge of our subject, and to possess antique examples of the art, with the result that enormous numbers of antiques were manufactured to meet the demand. Fortunately the bulk of the work bears the stamp of the eighteenth century, and is easily recognised.

It is necessary to observe that a large proportion of the gems are cleverly engraved, the rewards being so excessive that even the best artists were not above engraving forgeries of antique gems, polished very highly and with the very necessary addition of a name in Greek characters. The most impudent series of forgeries were the gems, about 3,000 in number, engraved on very fine stones, to the order of Prince Poniatowsky; they all bear the name of a supposed ancient engraver, and are quite well engraved, but from the pictorial nature of the designs, which generally include a free use of rocks, clouds, flying drapery, etc., coupled with an airy and superficial prettiness of treatment, there can be little difficulty in picking them out, though I have known them to be purchased for antique or Renaissance work. The same remarks apply to the other forgery illustrated.

With regard to the atrocious engraving, presumably a boar or pig, illustrated in the same series, I cannot express myself too strongly. This bad modern engraving, that impudently pretended to be antique, has nothing to recommend it, yet these wretched engraved stones, the work of ill-paid German workmen who produce them by the gross, are constantly bought and valued by persons who would not deign to look at an equally bad forgery of a picture or sculpture, and prove that a more extended knowledge of the glyptic art is necessary.

Nathaniel Marchant and Edward Burch, both Royal Academicians, are the prominent English gem engravers of the eighteenth century, and I am glad to acquit them of the charge of forging antiques. They worked in the classic style, as did their contemporaries, and both were engravers of intaglios for use as seals and ornamental purposes. Marchant was easily the foremost, many of his figure subjects being admirable and delicate examples of intaglio engraving. Notable among the numerous foreign competitors of these artists were the three Pichlers, father and two sons, engravers of cameos and intaglios, and Girometti, who also cleverly engraved dies for coins and medals.

Lawrence Natter, a German and a clever engraver, was a great offender with his forgeries

Hosted by Google

of antique gems, and, having some reputation in his day, said that ancient engravers used a certain parallel tool for engraving the hair, etc. This theory is not supported by the evidence of the antique gems, and Natter may have said this solely that he might more easily copy the parallel strokes of diamond point engraving by using this favourite modern tool. In the British Museum a finely engraved head, presumed to be that of Demetrius Poliorcetes, shows the use of this tool to great advantage, and in all probability was engraved by this very artist.

There is so much of interest in this period of which nothing is generally known, that I am loth to leave it, but after a few remarks respecting the Roman gem engraver Pistrucci, I will progress to my final stage, the consideration of the work of to-day. Early employed in Italy in fabricating antiques, Pistrucci came to London in 1805, rapidly became famous for his cameos and intaglios, and was appointed the chief engraver to the Mint. Whilst there he designed and engraved the elegant St. George and the Dragon that we use on some of our coins to-day, an engraving that clearly shows the superiority of directly engraved dies over the modern method of mechanically producing the die from sculptors' larger models. The point is interesting in view of the fact that for the first time in the history of our country our coins and great seal have been produced not by engravers but mechanically from large models by eminent sculptors, who cannot understand the requirements of minute work, or the technical difficulties to be overcome in order to produce a good coin in striking.

During the nineteenth century a great decline in the glyptic art set in. This was not the fault of the artist, but was due to various causes, chiefly the introduction of imitation cameos in shell, a valueless and easily-worked material, to the adoption of up-to-date methods of sealing with adhesive gum instead of wax, which made the elegant intaglio a luxury rather than a necessity, the use of steel dies to replace the seal, and the march of the fickle goddess of Fashion; in consequence of which artists of the Victorian Era turned their attention to heraldic engravings that show excellent technical ability but are lacking in design. It is therefore supposed that the art is dead, but this is wrong. True we have few in this country besides the clever heraldic engravers, but in France, owing to the influence of a school for the teaching of gem sculpture, carvings in precious stone have been produced within recent years that for ambitious conception vie with the large carving of the antique. Many of these sculptures are of extraordinary dimensions, considering the valuable nature of the material, and are unique monuments to the patience and skill of their authors.

The group of the Centaur with Deianira (Fig. 11), by Tonnellier, is of red jasper, and is in the Luxembourg Museum in Paris; it is very cleverly carved, as is also the figure of Victory by Lemaire, composed of various stones, jasper forming the cloak, white quartz the head and hands, the clouds of crystal, whilst other details are expressed in various stones of suitable colours, all pieced together with extraordinary skill. With the exception of Mr. A. Lyndhurst Pocock, no English artist has attempted work on such a large scale. The artistic carvings of this artist are equally interesting, and show in the clever manipulation of the colours of the stone a technical skill equal to that found in modern French gem sculpture.

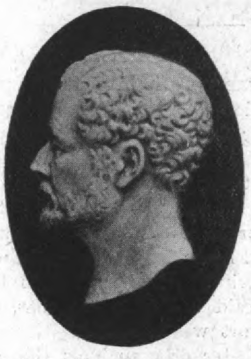

FIG. 12.—PORTRAIT.
(Cameo in onyx by Cecil Thomas, 1911.)

In order to enable my contemporaries to indulge in similar arduous undertakings, I might mention that the same principle is employed for this larger work that is used to engrave cameos and intaglios—*i.e.*, discs and tube drills charged with diamond dust are revolved in a lathe, the difference being that the size and strength of the tools must be sufficient to take the strain of cutting the heavy lumps of stone. The slitter and the tubular drill are the most valuable tools, the slitter removing piece after piece of superfluous stone, and the tubular drill cutting through the interstices of the group. When the bulk of the stone has been removed by these means, a large burr tool will model the forms, and by slow and painstaking effort bring the desired result. If the work is made up of various stones, then they must be fitted together by dovetailing, inlaying and insertion. The polishing is then obtained with copper wheels and emery, and

Hosted by Google

afterwards the various polishing powders. As an example of the labour involved in the more ambitious pieces, I might mention that in one case four valuable pieces of stone were carved before a suitable piece was obtained, one piece being discarded after three months' work had been expended. One year is often insufficient to produce a fine statuette in precious stone.

I have now dealt with a few phases of a beautiful art that is becoming too obscure; an art that in this country requires a fostering hand. We cannot expect our Government to aid the art as is done in France, so we must rely on private patronage and the valuable schools of art, on Societies such as this, and the Goldsmiths' Art Council, to teach and encourage a better understanding of gem engraving in this country. As an enthusiastic follower of the glyptic art it is my earnest desire to help forward this movement, and if I have contributed to this result and created greater interest, I am more than gratified.

DISCUSSION.

THE CHAIRMAN (Sir Arthur Evans), in opening the discussion, said it had been a great privilege to him to hear the author's interesting paper, because it came from one who was not merely speaking of the subject theoretically, but had practised it, who knew all the tools, and had studied all the technical processes of the different ages. Personally, he had had a long affection for the study of gem engraving, and he thought the best that could be said about it was that, so far as the history of art was concerned—though there were perhaps greater arts, such as the arts of sculpture and painting—the art of gem engraving was about the only art which could be followed continuously for a period of something like 5,000 years. Like other arts it passed through dark ages. Its beginnings were traced in Babylonia and Egypt; it then sprang up on an independent basis in Crete, which was far enough removed from the East and from Egypt to be capable of what Syria could not produce—an independent art. The wonderful work of early Minoan Crete, which he had done something to investigate, was extraordinary in its way, because in no country, not even in Japan, was naturalism carried to such a height as in some of the old Cretan works. But in Crete, as elsewhere, the period of the dark ages ensued when the decadence of the art was manifest. One found what were then the barbarous Greeks coming in and substituting rude linear copies. The people who had learned to work in hard material sank into working in soft material, which, as the author had pointed out, was one of the great differences. When a beginning was made, the people were quite incapable of working in hard materials, such as any form of crystal; they began in soft stone, like steatite, or a soft material such as ivory. That beginning was the ending. The work of Crete sank again into soft materials; the Greeks began on barbarous lines; then they gradually learned to work with harder material, and that very brilliant chapter in the history which the author had sketched began. They improved that by learning to work in cameos, though very little of the older Greek work was done in that line. Until the time of Alexander cameos were really practically unknown, and even then until the borders of the Roman period they were extraordinarily rare. But the work of gem engraving went on through Greek times; it was still kept up in great technical perfection in the earlier part of the Roman Empire, and then it sank again. He was not inclined to take such a low view of some of the Byzantine work as the author had done. It was barbarous in a way; it suffered in the same way as most other Byzantine work, but it was sometimes very careful and minute. But there again the art was practised on soft materials, most of the later Byzantine works being of steatite, and the same was largely the case in other parts of Europe. There were, for instance, Saxon seals not badly worked on ivory. Then, again, a revival took place in the West, a great part of which, he thought, had never been properly studied. Traces of it could be seen in the impressions of seals used on documents, but in the earlier English seals of the twelfth and thirteenth century there was some extraordinarily good work. It might be partly on metal work, but it was very hard to separate the two. Looking over some impressions of twelfth and thirteenth century English seals, he was greatly struck by the fact that probably, in this country and in France, the art at that time attained a higher degree of excellence than it did in Italy, and that was found in some other branches of art. By the fourteenth and fifteenth century, the time of the Cinque-Cento, the Italians went ahead. One point to which the author might have referred was the intimate relation between gem engraving and the engraving of the dies of coins, the engraving of metal matrices, and also of rings in precious metals. So far as he could see, in the earlier periods there was no real distinction to be made as far as the design went; there was a great deal of resemblance in technique. The great Sicilian engravers, for instance, who produced the most beautiful coins in the world, were also engravers of gems. What Pistrucci did for St. George and the Dragon, or for the beautiful Waterloo medal, which he copied from a coin of Magna Graecia, was done by the great Sicilian engravers of the fifth century before the English era. There was a close inter-relation between the two, and they could not be separated. It was because no real school of gem engraving existed that the engraving of the British coinage had sunk to its present level, and that the methods of procedure for producing medals were opposed to everything that was regarded as fine art in that material in any age but the present. He thought that process of reduction to which the author had

Hosted by Google

alluded, which transferred the methods of one art to another, was wholly wrong, and wholly vicious. Personally, he was in the unfortunate position of being a collector, having collected gems in Greek lands and elsewhere for a great number of years. It was exceedingly difficult to tell what was genuine and what was not, and he did not know that after studying for many years he would have been able to recognise the ancient work from some of the eighteenth century copies, if he had not acquired a certain instinct from observing what actually came out of the ground. When once the eye was trained to that, some kind of criterion could be formed. The author had asked at the close of his paper, what the future of gem engraving was to be in this country. One was almost inclined to despair. It was partly the fact that at the present day seals were no longer necessary, gum being used instead. In the days of Egypt, Babylonia, and ancient Crete, the seal stood in the place of a key, one's possessions being secured by sealing them up. Even when locks and keys came in, as they did in classical times, gem engraving was at a certain disadvantage. Now, however, that envelopes were simply licked there seemed to be a very little future for intaglios; and, owing to the fashion of heraldic designs, even when seals were used they were generally not of any real artistic merit, and were made of metal. He thought, however, that possibly there might be some future for cameo engraving. The cameo had perhaps some future as a decoration, and ladies' fashions might bring the cameo again into vogue. All those present probably had a vague memory of the chaste shell cameos of the early Victorian period; they were not very beautiful, and the decadence from hard beautiful agate to shell was a great disadvantage, but nevertheless it was the reflection of an old and excellent tradition. It seemed to him that for brooches and for other purposes it was possible to revive the cameo, and he was sure everybody wished the author and his fellow-workers the greatest success in reviving that ancient and beautiful art.

Professor Ernest A. Gardner said his knowledge of the subject, which was very limited, was confined entirely to the historical and artistic side, and he had therefore learned a great deal from hearing an exposition on the subject from somebody who had a practical knowledge, who knew what the tools were, and how they were used. There was one point which had been hardly referred to as one of the causes of the decadence of gem engraving, and of the somewhat despondent view taken of it both by the Chairman and the author, to which he wished to refer. When it was found that the material in which anything was carried out was thought more of than the artistic skill that was used in producing it, then art was in a very bad way, and he believed that was what was the matter with the people of this country at the present moment. That was evident from the horrible misuse of the word gem which was still prevalent. The author actually had to begin his paper by defining what a gem was. The man in the street believed that when a gem was referred to it meant a precious stone, a diamond, or a ruby, or whatever it might be. As a matter of fact, a gem was essentially a work of art, a thing which received its value from the exquisite work that was put into it. Of course the material must be worthy of the work, and many of the precious stones were the most beautiful and suitable for that artistic workmanship, but it was the artistic workmanship which was the essential thing. It was because the people of this country had so largely lost sight of that fact that the art of the gem engraver had fallen on such evil days.

Dr. T. G. Pinches thought there was one point in connection with gem engraving in general which should not be forgotten, namely, the importance of the material. If the Babylonians had not used hard stone for their wonderful engravings they would not be in existence now, so that the durability of the stone was an essential element. In considering the difficulties connected with the subject, there were some points which required elucidation. An important question, for instance, was that of the use of the lathe. Personally, he began life as a die-sinker; he did not know anything about stone seal engraving; and he found, when he attempted to engrave on a curved surface, that his graver slipped off at a tangent. He had to follow the curve of the surface with his hand, a difficult thing to do. It struck him that the tubular drills, to which the author had referred, would have to be held very steadily indeed in order that they should not slip off the surface being engraved at the first attempt to turn them. That point, it seemed to him, made it practically certain that some kind of lathe must have been in use even in very early times. A great deal might be said about the cylinder seals which were met with in such large numbers among Babylonian antiquities, and also about the history of the art in that country—a history which reflected the political changes that took place. The peculiarities of the methods were well worthy of notice, particiliarly their sketchiness. He imagined that the skirts of the figures which were represented on the cylinders were produced by simply grinding away a portion of the stone on a flat surface, which might even have been a kind of grindstone. Whether that was the case or not he did not know. One peculiarity of the history of the art was that a long time ensued before the artists hit upon the importance of a decided outline to the body and the robes of their figures. Another point which must have contributed enormously to the perfection of the art was that if a beautifully engraved gem was held up to the light it was possible to see the contour of the figure, the outline of the cheeks on a head, it thus being possible to test the progress of the work without having an impression made. The present low position of the art was one much to be regretted, and more attention should be paid to it in this country and elsewhere. One of the things the Government might do to benefit it would be to take off the tax

Hosted by Google

on heraldic devices when applied to seals. It was a very hard thing that a man could not have any device he liked engraved on a piece of stone, because for some reason or other the Government thought it proper to put a tax on it.

MR. A. LYNDHURST POCOCK thought the definition of the word "gem" given by the author was correct, namely, that the art, the beautiful design, constituted the gem in whatever material it was made. The art undoubtedly had first place; but how was a line to be drawn between works executed in soft materials, such as serpentine, lapis, etc., and harder stones from, for instance, labradorite to the diamond? He thought a strong line should be drawn between those stones which can be scratched with steel and those that could not. A lapidary working in stone soft enough to be cut by steel was not, in the fullest sense, doing true lapidary's work; his special tools were not necessary. They might have gems in shell, wax, paint, or any other material, but they were not lapidary's art unless the material they were cut in was harder than could be cut with steel tools. To make that point more clear, he wished to say that a lapidary might call himself a sculptor, but a sculptor could not call himself a lapidary. That art, owing to the great expense and labour in production, could never be produced in quantity, unless the artistic patronage was considerably increased. Mechanical production by sweated labour, or by persons who had no real love for it, was a degradation alike of the art and the producers of it. The supply could not exceed the demand without very much lowering the standard, which it should be their aim to raise to its highest.

MR. CECIL THOMAS, in reply, said he was particularly grateful to the Chairman for the kind words he had spoken, and for the appreciation the audience had shown of his paper. The point that had occasioned the greatest comment was the question of the engraving of dies and stones. As the Chairman had mentioned, the engravers of stone in Greece, and later in Rome, were also the engravers of matrices for dies, and it was by reason of that fact that they were able to produce such beautiful work so splendidly illustrated by their coins. Since then engravers had worked in both materials. It was not difficult for the engravers of stone to work in metal, but owing to the present commercial age they had become split up, and the engraver of one material confined himself exclusively to it. He noticed that the Chairman did not agree with his opinion regarding Byzantine art. The art of gem engraving was classical, and the nature of the material demanded fine technique in order to bring out the fine qualities of the stone. It was not suitable for rough and careless work such as was found in Byzantium, although the decorative qualities of Byzantine work gave it a charm that was perhaps not found in work of a more classical period. He quite agreed with the Chairman's statement that the English seals of the thirteenth and fourteenth century were most beautiful productions of art, and he wished present-day engravers would follow in those traditional footsteps and produce work that came within the same pale. It had always been a great regret to him that gems of that period had not been found, because he felt that early English gems were probably as beautiful as early English seals. It was impossible to look into the future and predict what the future of gem engraving would be. He tried to see something rosy, but there had not been much rosiness since the days of the shell cameo, which was mostly responsible for the ruin of the art. After a little practice, it was possible to produce a beautiful cameo in shell with a steel tool, provided one had a certain amount of artistic ability, but it took at least six years before it was possible to attain to anything like the technical skill necessary to produce the minute work that was required in seals containing heraldic devices. The school in Paris was a most exclusive one, into which it was difficult for an Englishman to get, and gem sculpture was there taught in the finest possible way. There was nothing commercial about it, it being purely for the sake of the art that gem sculpture was taught, and the French Government actually provided an annual grant to the principal engraver, in order that he might keep the art alive. A good many comments had been made with regard to the word "gem." Personally, he had used the word in its correct and original sense, meaning that it was anything choice, although he feared that it was difficult to say where the line of demarcation should be drawn, separating what were suitable gem stones from what were not. As an engraver, he thought it a pity that some such line as Mr. Pocock had suggested could not be drawn. Mr. Cyril Davenport, who was unable to be present at the meeting, had written to him, saying that among other important points raised in the paper he was particularly interested in the treadle that was used with a bow drill. Such an attachment, Mr. Davenport thought, would have been difficult in early times, but was it at all possible that one man worked the bow rythmically, while another manipulated the stone against the cutting edge? Personally he thought it was very difficult to say exactly what the ancient engravers' tools were and how they used them, but he agreed with Mr. Davenport that one man might have worked the drill and another controlled the stone. That would give that control over the tools which was absolutely necessary in order to obtain the results produced. He quite agreed with Dr. Pinches' suggestion that in engraving the rounded surface of a cylinder the tool would slip. Some way of starting must be obtained. This would make necessary some advanced method of revolving the tools as had been suggested. The early work on stone, however, showed that the corundum point was largely responsible for the finish of the engraving; by experiment he had proved that

Hosted by Google

with labour and patience it was possible to obtain any result with this simple instrument. In conclusion, he would like to express his thanks to Mr. S. Henson, Mr. G. Donne, Mr. S. Pegg, Mr. A. G. Ready, and Mr. F. Hyams for lending the interesting examples exhibited.

On the motion of the CHAIRMAN, a hearty vote of thanks was accorded to Mr. Thomas for his interesting paper, and the meeting terminated.

SOUTHERN PERSIA AND ITS DEVELOPMENT.

The critical state of affairs in Southern Persia, and the ominous rumours of the approaching partition of the country, are the outcome of a series of events which have been shaping for the worse for some years, and which have now reluctantly compelled the British Government to take serious measures for the protection of British Indian traders domiciled in the country. The last Consular Report for Bushire for 1910-11 sheds considerable light on the occurrences which, during the past year and a half, have gradually brought the break up of the Shah's dominions within the range of proximate politics. Bushire with its hinterland is part of the Persian Province of the Gulf Ports, Bushire itself being the headquarters. The Persian Government only assumed effective control of Bushire sixty years ago, till when the town had more of an Arab character. Even now, to a large extent, the population of the town and its surroundings is more Arab in blood than Persian. The inhabitants follow the occupations of cultivators, traders, fishermen, labourers, and coolies. In the last-named capacity their services are in large demand for work in Basra and on the Tigris, on account of their stamina and energy being superior to that of local Arabs. The garrison of the town and district of Bushire consists of about 200 soldiers and 20 gunners. There is little connection and intercourse between Bushire and Northern Persia. The immediate hinterland is tribal in character, each district being ruled by a local chief or Khan, and comprising twenty to thirty or more villages. The tribesmen, mostly well-armed, and owing feudal service to their chiefs, have the land under cultivation of wheat and barley. The aggregate population south of the mountain range is estimated at upwards of 83,000. Extensive smuggling of rifles and ammunition into the country has permitted the chiefs to arm their men well, and this smuggling industry—one of the evil results of the present Custom tariff—has considerably enriched the districts. But neither the net proceeds of the Bushire Customs, which are assigned to the service of the Imperial Bank of Persia Loan for £1,250,000, nor the net revenue from all sources which is despatched to the capital, is expended on the needs of the province, so that the dilapidated condition of the town is now becoming more and more conspicuous. In 1907-8 trade in Bushire was flourishing, but since then, owing to the focus of Persian anarchy having shifted to the southern provinces, the hinterland and the whole province of Fars have shown a steady decline. The year 1910-11 shows an almost unvarying record of robberies and raids along the caravan route, and the amount of claims put forward by British commercial houses and traders, and entered against the Persian Government for looted goods or denials of justice, now totals about £4,950 as regards claims filed at Bushire, and about £9,000 as regards claims filed at Shiraz.

In Fars, during the year under review, the bazaars were congested; pedlars, village dealers, and petty merchants could not circulate freely, and Lar, Fasa, Kazerun and Behbehan were the scenes of considerable fighting and plundering. Along the two main trade routes to Isfahan, which is one of the most important commercial centres of Persia, unfavourable conditions have also prevailed, and cotton imports from Manchester in particular have markedly declined. And, be it noted, while Russian piece goods into all Persia show an increased import during 1909-10 of 1,318 tons, there was a decrease of British goods to the extent of 1,874 tons.

No steps have been taken by the Persian authorities to put down the levy of blackmail which is such a heavy charge on trade with Shiraz. This is the more flagrant because the abolition of all exactions in the interior was one of the most important conditions of the Commercial Convention of 1903. These exactions amount in the aggregate to from £1 7*s.* 5*d.* to £1 14*s.* 7*d.* for every ton of goods carried along the 180 miles of route between the two towns.

The Consular Report for Bushire for 1910-11 says there are still no signs of the economic development of the southern provinces of Persia, and the improvement of methods of transport by the construction of railways has become a real necessity.

In connection with this, it is important and interesting to note the progress that is being made with the Trans-Persian line, which is strongly supported by Russian banks, and which various English financial houses are also interested in. This line contemplates the running of a through line from Europe to India by way of Vladikafkar, Tabriz, Teheran, and Seistan. The Government of India, whose co-operation is, of course, necessary, have already deputed Mr. Johns, the Chief Engineer of the Oudh and Rohilkhund Railway, to carry out the necessary surveys for the best alignment on the Indian side—that is to say, in Baluchistan and Southern Persia. The Government of India have, however, shown discrimination in stipulating that the surveys shall not be confined to the route favoured by the promoters of the Russo-Persian line, but shall include various feeders and branches, one running to Mohammerah, at the head of the Persian Gulf, which would thus admit of being prolonged, by way of Basra and El Jauf, through Northern Arabia and Sinai, to the Suez Canal. Such a line would prove of great importance, as it would unite Egypt and India, and fulfil generally the conditions of an All-British railway, which a trunk line passing through Germany, Russia, and

the Russianised sphere in Northern Persia could never pretend to possess. For instance, most "Railway to India" projects claim at the outset the privilege of conveying the mails to and from the East, but it is hardly conceivable that England would ever permit the mails to her great Eastern Dependencies and Colonies to be entrusted for safe conduct to Germany and Russia. In time of peace this might be well enough, but in case of war the necessity of a mail route within reach of British control would clearly be paramount.

The greatest interest, therefore, attaches to the coming development of Persia, for which pending events are now paving the way.

THE WEAVING INDUSTRY OF EGYPT.

A merchant, who travels continually between England and Egypt, assured the writer a year ago that there was no weaving industry in Egypt. To use a homely phrase, he "spoke without his book." A considerable part of the peasant population earn their living in this way. There is no export, as most of the stuff made is used in the neighbourhood, or, at all events, in the country. There are technical schools at Tonkh, Fayoum, and Mansourah, and within the last three years there has been a special inspection, by order of the Government, to study the desirability of furnishing professional instruction. The difficulty in the inspection has been that the fellaheen treated the efforts to help them with unfriendliness and distrust, and were not inclined to furnish reliable data.

In the province of Kalioubyeh there are eighty-seven villages, each containing from six to thirty looms, except the village of Kalioub, which contains several hundreds. There is rarely more than one in the same house, and this is generally set up in a dark, dirty little room. Occasionally, however, something rather more important is to be seen, and more like a regular workshop. At Kalioub, for instance, there are small manufactories, with as many as thirty looms. Linen, cotton, and wool are used. Silk does not appear to be used in this province. The raw materials are generally grown in the neighbourhood, but at Kalioub they have to be bought from Cairo.

The cotton, wool, and linen are all spun by hand by old men and women, and the thread is usually put direct on to the bobbins rather than loomed into skeins. At Kalioub a great stock of cotton and linen, ready for sale, is to be seen; sheets, table napkins, towels, bed covers, handkerchiefs, stuff not made up, etc. This is all used in neighbouring villages. There is a roughly-made stuff, rather like sacking, which is used for men's shirts. It is bought in the natural colour at the weaver's, and made up by the women. In the smaller villages this is almost the only use to which linen is put. Wool is woven for the "galibiehs" and "deffiyehs," as the outer garments are called, and dyed black or brown. It is also used in the manufacture of carpets.

Some of the prayer-carpets show considerable imagination. The simplicity of the needs of the inhabitants in distant localities makes it quite unnecessary to have any stock of garments kept on hand for sale. The men wear two garments, and the women one. If a new one is wanted the weaver is directed to make it. In fact, the weavers do not always have work enough to keep them occupied all the year round, and spend a part of the time in the fields.

The looms are mostly of native manufacture. The most important parts, such as the combs, are bought in Cairo. In the small villages the looms are of the simplest description. At Kalioub they are slightly more complicated, and are sometimes worked with four or six pedals. The stuffs woven are one metre, ninety centimetres wide. The loom is generally worked by a man and his son.

From the province of Fayoum some 20,000 woollen "deffiyehs" are sent annually to Tanta, Alexandria, and Syria. In the smaller villages of Fayoum enough flax, cotton, and wool is produced to furnish the local weaving trade, but at Medinet-el-Fayoum cotton from India and America is used, and at Fodam big quantities of wool are bought from Cairo. A large quantity of rather coarse material, in black and white, is used for women's garments, and called "omache harim." It is rather like crochet in appearance. From Fodamin considerable quantities of cotton material are sold by the piece of fourteen metres at 2*s.* 5*d.* This represents two days' work. Where workmen are employed the average salary is 1*s.* 2½*d.* a day.

There are forty weaving manufactories at Damietta, in the province of Dakahliyeh. Some of these contain twenty looms, but most only two or three. One manufacturer turns out 170,000 metres of silk a year. This represents about a third of the whole local industry. There are about 1,500 persons engaged in weaving in the city. At Manzala a lot of raw silk is spun, all of which is sent to Mahalla-el-Kobra to be woven. About four or five hundred men and children, and between five and six hundred women are employed at Manzala. There were formerly many looms at Manzala, but the trade has been transferred to Mahalla-el-Kobra.

There are about three hundred cotton and linen weaving looms in Dakaliyeh, and about twelve hundred persons working at them. The village of Mit Khamis, which formerly possessed two hundred looms, has only thirty-six to-day. Farascour has the greatest number of wool looms in the province, viz., fifty.

The raw silk used for weaving at Damietta comes mostly from China. None of the flax used in the province is produced locally. The linen woven is used for men's shirts, and sent to big towns without the province; handkerchiefs and cloths are also worn. There is not so much cotton woven in the province as linen. The produce of the wool looms at Kom-el-Nour is sent to different parts of the province, but in other villages the trade is strictly local. The looms are all very primitive. The

Hosted by Google

wool, cotton, and silk are spun by men and women too old to do anything else, or by men working in the fields during spare time. Thus, if a fellah wants a new garment he will shear one of his sheep, spin the wool, and take it to a weaver.

Silk weavers at Damietta earn 1*s.* $2\frac{1}{2}$*d.* to 1*s.* $5\frac{1}{2}$*d.* a day, and they can weave twenty metres. The silk is first given to women to clean, 5 to 8 per cent. being rejected. The combings of silk are then put on the "konfiyeh," which is of light reed, cone-shaped, with a central spindle occupying the axle of the cone. From the "konfiyeh" the silk is rolled in two or more strands, ready for the cylinders of the "radei." These are put on the "doulab," and the silk is worked on to bobbins. Men who work the "radei" are paid 1*s.* $2\frac{1}{2}$*d.* a kilogramme, and they do one and a half kilogrammes a day. Women earn 1*s.* $0\frac{1}{2}$*d.* a kilogramme. At Manzala the raw silk used comes from China. A piece of rather coarse silk, 15·50 metres long, can be made in a day. The silk is dyed black before being woven, by soaking twenty-four hours in a bath containing pomegranate skins. A treatment with sulphate of lead and gall-nut follows, and it is then dried in the sun. In many localities the weaver's trade is hereditary.

At Beni-Adi excellent examples of hand-weaving in the way of "galibiyehs" are to be had. These garments are made of specially selected wool, and are very durable. They are sold by weight. Wool carpets are also made. This trade is in the hands of women. Both carpets and "galibiyehs" are sold by weight. They cost about 7*s.* a pound. There is a small carpet industry at Beni-Souef. At Abou Kerkas there are seven thousand inhabitants, and weaving is the chief industry. At one time all the thread was spun locally, now much is bought from Manchester. Stuffs of pure wool, seven metres in length and seventy-five centimetres wide, fetch 25*s.* locally. Pieces of mixed silk and wool, seven metres long and sixty centimetres wide, fetch three guineas. It is difficult to get exact figures, but a local merchant stated that 65,000 lbs. of wool thread, in the raw state, are sold for about £611 every year in the town, whilst 13,000 lbs. of thread, composed of mixed silk and wool, fetch about £408.

ARTS AND CRAFTS.

Stained Glass.—Stained glass windows nowadays do not, as a rule, evoke much enthusiasm, or, indeed, much comment of any kind. We generally hear more about how much they cost and whom they commemorate, than about the windows themselves and the person responsible for their design and execution. It is probably because Bunyan is a familiar household name, rather than on account of the undoubted interest of the glass itself, that the new window at Westminster Abbey has aroused as much attention as it has done. There is a tendency amongst the educated general public to cling tightly to the theory that the old methods of glass-making are lost, and that modern glass must inevitably be a thin and rather poor material, with little or none of the charm of colour which we find in old work. Just how far that idea is well founded it is, of course, rather difficult to say. It may be true that the chemical purity of the glass of to-day robs it of some of its unexpectedness and interest, but the beauty of colour of the old windows is undoubtedly due in great measure to the effect produced by the weather on the outer surface of the glass, and it is quite possible that two or three hundred years hence some of the best modern stained glass will, if it survives, have much the same quality that we admire in the old work.

Modern English stained glass may be looked upon as the outcome of the Gothic revival. It was that which gave the death blow to the eminently unglasslike windows of the early nineteenth century, and brought about a return to earlier and more workmanlike methods. Under its influence, the desire for pictures painted on glass died out, and a whole school of workers grew up whose ideal of glass was intimately connected with glazing. The windows they produced were by no means always satisfactory, and in their desire to make their glass look old and rich they occasionally overstepped the limits of honest workmanship; they were often hidebound by their Gothic tradition, and content to copy old designs and methods rather than try to develop them. But, when all that has been said, we must admit that the ordinary trade work of to-day is immeasurably better and more workmanlike than that of the Early Victorian period. Moreover, the very best windows that have been put up of recent years are not only good pieces of workmanship but real works of art.

The New Window at Westminster Abbey.—The technical interest of the Bunyan window lies in the fact that Mr. Comper, while adhering in a sense to traditional methods, has developed them. It was noticeable in the Sir Benjamin Baker window, put up under the direction of the same artist a short time ago, that the lead lines were unusually thin. In the Bunyan window we find this same thinness of line combined with a less ordinary and less strictly traditional form of design. The new lights are filled with large medallion subjects, separated from one another by spaces occupied by a diapering of delicate quarry work — an arrangement which makes them much easier to read than early medallion windows or even than some of the later subject windows to which they are in some ways more closely allied. Quarries, by the way, are hardly what one expects to find in a window planned like this one, and, though the method of the rest of the painting is quite in keeping with them, one is inclined to wonder whether some simple grisaille ornament on a larger scale would not have been more interesting, though it would possibly have been rather more costly. The thinness of the lead lines goes well with the delicate painting on the figures, and

Hosted by Google

the harsh contrast between heavy leading and delicate painting, which rather shocks one at times in late fifteenth and sixteenth century glass, is thus done away with. Indeed, if there were no need to strengthen a stained glass window with additional supports, and if the ideal of a window is taken to be rather pictorial representation than beauty and brilliancy of colour, the Bunyan window would mark a really remarkable new departure. But, whatever our theories may be about the second point, saddle-bars are not theories but very solid facts. The lights at Westminster Abbey are broad, and it takes about twenty-four bars to each light adequately to support the glass; and to do their business properly, these bars have to be thick and heavy. In the ordinary way, the thickness of the lead lines, which for the most part run in a more or less upright direction (while the bars, of course, are horizontal), helps to balance the saddle-bars and to keep them from becoming unduly pronounced. When the leads are thin, the bars stand out with a startling prominence. Indeed, it is difficult to believe until one has counted them, that they are not more numerous in the new lights than in the other windows of the Abbey. Of course, the position of the new window makes it impossible to get a distant view; but looking at it from close at hand, as one is bound to do, one is inclined to think that thicker lead lines would have helped and not hindered the general effect of the window. After all, the painting might, without seriously affecting the result, have been a trifle less delicate, and the bars were a condition laid down by the exigencies of the case. So far as architectural drawings are concerned, modern architects may be quite justified in quarrelling with the good thick, vigorous line advocated by one of the leaders of the Gothic revival, but in dealing with a material like stained glass there is a very good use for it.

The Training of Craftsmen, Designers, and Teachers of Design.—There seems, at last, to be a decided movement towards the systematisation of the training of designers, teachers of design and skilled workers in the artistic crafts. The London County Council appears to be turning its attention to its trade scholars, and trying to bring the work in the technical schools more into line with workshop practice, an effort which ought to result in training a race of workmen who, whilst artistically better equipped than their forerunners, are no whit behind them in technical accomplishment. The trouble with the London trade schools has been very largely that the boys when they left them were not sufficiently advanced technically to enter the various trades as improvers, and were too old to be welcomed as apprentices or willing to take beginners' wages. If, by a certain amount of readjustment, the boys can begin their special training a little earlier, and be taught rather more of the technical part of their work in a way which fits them better for the workshop, there seems a good prospect of the schools fulfilling the functions for which they were created far more successfully than heretofore.

For the country, as a whole, the larger task of making new arrangements with regard to the design teaching in the schools of art has been undertaken by the Board of Education. The new conditions for examinations in art and certificates for teachers of art put out by the Board have, of course, a very intimate connection with the teaching of design. How far the new arrangements will bring down the numbers of students in the schools, and from that point of view affect them adversely, is a question which only teachers can be expected to answer. But probably few people interested in art will regret the passing away of the present machinery for awarding teachers' certificates.

Apparently after this year the Board only intends to examine serious students who have studied drawing for at least two years, whilst students who wish to pass in painting, modelling, or pictorial design, will be expected to study for a further period of two years. In the case of design students, an examination is contemplated of "such a standard as could be attained through regular attendance at evening and other part-time classes in the intervals of employment for a period of four years after the age of sixteen." But the candidates in this subject will not be obliged to sit for the drawing examination first. Teaching certificates will, when the new regulations come into force, only be given to students who submit evidence of having received a sufficiently good general education, and of having been trained in the theory and practice of teaching, and who have gained the Board's certificate in drawing and one other subject, or passed the final examination of the Royal Institute of British Architects in architecture. The new scheme seems in many ways a very great improvement on the old one, but it hardly appears to encourage design students to sit for the examinations at all since, apparently, their certificate when they have gained it, not being accompanied by a certificate for drawing, will not entitle them even when they have fulfilled the other necessary conditions to hold positions as teachers. Students seem to like examinations, or, at any rate, certificates, and there is a feeling abroad that the withdrawal of the more elementary examinations of the Board may necessitate the substitution of other tests of some kind in order to keep up their interest; but it is difficult to see why a designer wants a certificate of the nature of those to be issued by the Board under the new arrangements, unless he is going to teach. If the new certificates will not enable him to do that, it is not very obvious how it will benefit him. If this arrangement comes into working order unchanged it seems as though practical designers and craftsmen will be rather hardly used, and the teaching of design is likely to pass into the hands of people who are qualified teachers rather than qualified designers. It is surely a right instinct which has kept the authorities from forcing designers through the same course of

Hosted by Google

drawing as students who are studying from a totally different point of view. But why not carry the idea a little further, and allow these students to be taught by masters who also regard drawing not primarily pictorially, but from the standpoint of design? As the scheme at present stands, it would seem that, if persons were admitted as teachers who had passed in design instead of in drawing, and in one other subject, the design teachers would have a less severe training than the other art teachers; but surely any lowering of standard could be guarded against by requiring evidence of practical working experience.

CORRESPONDENCE.

ILLUMINATED MANUSCRIPTS.

In the matter of the admirable letter by the lady who signs herself MacIver Percival in our *Journal* of this date, I am able very pertinently to support her view of the extreme difficulty, notwithstanding their seeming ease, of the feats of interlaced wire-work to which Sir Walter Armstrong referred in the discussion on Mr. Davenport's paper anent "Illuminated Manuscripts," published in the *Journal* of the 2nd inst. Among the Dravidas of Central India, and the Mongolo-Dravidian Bengalis, not only armlets and anklets are made of bent, and twisted, and interlaced wire, but the smaller household images of the gods are often fashioned of it, and, now and again, so picturesquely as to be aesthetically impressive. It all looks most simple, until you try to imitate these masterpieces of manipulative dexterity; when you find it to be just as impossible as to build the "Weaver-bird's" [*Ploceus Baya*], or the "Tailor-bird's" [*Orthotomus longicauda*] miraculous nests; and for the reason that the magistery of them all—idols and bird's-nest—is "the long result" of practice in the art and craft of interlacing, transmitted from parents to their offspring, through countless generations. "Ars est celare artem." But again, and it is the very first of the aphorisms of Hippocrates: "Ars longa, vita brevis." This is the leading lesson to be learned of the hereditary handicraftsmen of India, and the East generally, by the manufacturers—wrongly so named—of the "applied arts" of Europe; while Europe, on its side, thanks to its inheritance in the traditions of Phidias, Praxiteles, and Lysippus, and of Apelles, Parrhasius, Timanthes, and Zeuxis, is the natural teacher of India in the "fine arts,"—architectonic, lithurgic, plastic, and graphic.

GEORGE BIRDWOOD.

February 9th, 1912.

NOTES ON BOOKS.

THE NATURAL HISTORY OF CLAY. By Alfred B. Searle. Cambridge: At the University Press. 1s. net.

This little volume forms part of the well-known series of Cambridge Manuals of Science and Literature. It is divided into six chapters, dealing respectively with the chemical and physical properties of clays; clay and associated rocks; the origins of clays; the modes of accumulation of clays; some clays of commercial importance; and clay-substance, theoretical and actual. It also includes a bibliography, which will be of much service to those who wish to study the subject in greater detail.

It will hardly be necessary to remind readers of the *Journal*, in which Mr. Searle's Cantor Lectures on Brickmaking appeared in 1910, that the author is a recognised authority on clays of every description. He writes in a clear and simple style, and contrives to give an excellent account of his subject in a very small compass.

READINGS IN ENGLISH HISTORY FROM ORIGINAL SOURCES. Book IV. Edited by R. B. Morgan, M.Litt., and E. E. Kitchener, M.A. London: Blackie & Son. 2*s*. 6*d*.

These volumes, of which the fourth has just been issued, consist of "selections from original and (wherever possible) contemporary sources, illustrating the chief events in English history, and arranged chronologically." There seems to be a good deal to be said in their favour. They are, of course, open to the obvious objection that they are "snippety"; but it may be doubted whether the ordinary schoolboy's knowledge of history is ever more than this, even if it is as much. In the present volume, which covers the period 1688-1837, we have some fifty passages, including Marlborough's account of the battle of Blenheim, Clive's account of the battle of Plassey, Wellington's account of Waterloo, the birth of Methodism by Wesley, and a description from the Creevey papers of a terrifying journey in one of the first trains, when Mr. Creevey was whirled along at the frightful pace of twenty-three miles per hour.

The passages seem to be carefully selected, and judiciously varied to represent different phases of social as well as political history. They certainly do something to put a little flesh on the dry bones of the ordinary school history manual, and it is even possible that here and there a boy may be found who may be induced by the reading of these extracts to dip a little more deeply into the original authorities.

GENERAL NOTES.

LONDON SCHOOL OF TROPICAL MEDICINE.—A meeting will be held at the Mansion House on Wednesday, February 28th, at 3 p.m., to hear a report in regard to the work and progress of the school. The meeting will be under the presidency of the Right Hon. Sir Thomas Crosby, M.D., Lord Mayor of London, who will be supported by the Right Hon. Lewis Harcourt, M.P., Secretary of State for the Colonies, and others.

Hosted by Google

Members of the Royal Society of Arts, who are interested in the school, are invited to attend the meeting. Those who intend to be present are requested to apply for cards to Mr. P. Michelli, Secretary of the Seamen's Hospital, Greenwich, S.E.

MEMORIAL TABLETS. — A memorial tablet has been affixed by the London County Council to No. 28, Newman Street, Oxford Street, which was for forty years the home of Thomas Stothard, painter and book-illustrator. The house was purchased by him in 1794, the year in which he was elected a Royal Academician, and he continued to reside in it till his death in 1834. A tablet has also been affixed to No. 8, Canonbury Square, N., the house in which Samuel Phelps resided during his management of Sadler's Wells Theatre. The scene on the opening night, when Phelps produced *Macbeth*, is described in a well-known passage by Dickens. "It was performed amidst the usual hideous medley of fights, foul language, catcalls, shrieks, yells, oaths, blasphemy, obscenity, apples, oranges, nuts, biscuits, ginger-beer, porter, and pipes—pipes of every description were at work in the gallery, and pipes of all sorts and sizes were in full blast in the pit. Cans of beer, each with a pint measure to drink from (for the convenience of gentlemen who had neglected the precaution of bringing their own pots in their bundles), were carried through the dense crowd at all stages of the tragedy . . . Fish was fried at the entrance doors. Barricades of oyster-shells encumbered the pavement. Expectant half-price visitors to the gallery howled defiant impatience up the stairs, and danced a sort of carmagnole all round the building." Dickens also gives an account of the steps taken by the new manager to reduce this chaos to order, and so successful was he that "within a month the Jack Ketch party, thoroughly disheartened and amazed, gave in; and not an interruption was heard from the beginning to the end of a five-act tragedy!"

A RAIL GAUGE.—A patent has just been taken out by Mr. T. B. Grierson, M.Inst.C.E., for a new method of weighing rails in the permanent way. The gauge consists of two arms firmly pivotted, and made to embrace exactly the head of the rail. It carries a slide and sliding rod, the sliding rod being divided on one side to indicate pounds weight per yard, and on the other side to parts of an inch to show the rate of wear. The method of use is this: the place to be gauged is brushed clean with a steel brush; the gauge is applied to the rail head, and held firm while the slide rod is pushed down, until it touches the head of the rail; it is then clamped by means of the milled head, removed, and the reading is taken, which will indicate the number of pounds per yard weight of the rail. This takes less than a minute to do. The advantages claimed for the gauge are:—(1) The rate of wear and the resulting weight of the rails per yard can be ascertained in a moment, without removing them from the permanent way; (2) rails can be weighed or measured at any time without stopping the traffic or working single line as at present; (3) the life of the rails will be lengthened without any risk, by leaving them in the road until they are worn down to the line of maximum wear, shown on the rail gauge; (4) the gauges can be applied to any section of rail and to all kinds of permanent way, including tramways; (5) in addition to the enormous saving which will be effected by the use of this method, and in the maintenance of the permanent way, there will be an increase in the traffic receipts by the doing away with the stopping of goods and passenger trains for the purpose of weighing the rails, as at present.

THE HOTEL INDUSTRY ON THE FRENCH RIVIERA.—A recent report published in the *Riviera Hôtelière*, a journal devoted to the interests of the "Union Régionale des Syndicats Hôteliers de la Côte d'Azur," gives some interesting statistics respecting the hotel industry on the French Riviera. From this it appears that the total number of hotels in this district, which extends from Toulon to the Italian frontier at Ventimiglia, embracing a coastline of upwards of 120 English miles, is 577. This does not include hotels with fewer than 20 rooms, or boarding-houses. Of this number, 66 are at Mentone, 91 at Monaco, 170 at Nice, 71 at Cannes, 31 at St. Raphael, whilst the remainder are scattered in other smaller places. The total capital engaged in this industry is stated to be 640 million francs (£25,600,000). This probably is beyond the true value, for it is well known that many of these undertakings are over-capitalised. With regard to the nationality of the proprietors, 20 per cent. are French, 10 per cent. Italian, 25 per cent. German, and 45 per cent. Swiss. A still larger proportion of the employees and servants are of the latter nationality.

PUBLIC WORKS IN TRIPOLI.—The works for the improvement of the port of Tripoli are to be carried out at once. The first part, which is to be completed by the end of this year, includes the construction of a breakwater 625 metres (687 yards) in length, to be built on the reef or line of rocks which affords the only protection to this port at the present time. This contract, which will be carried out by a well-known Italian firm, amounts to two million lire (£80,000), and also includes some other works of less importance. Further contracts will be given out shortly for the construction of quays, dredging, etc., and form part of the scheme lately approved of by the Minister of Public Works for the improvement of this port. If this is carried out, Tripoli will become one of the best ports on the North African coast. Extensive harbour works will also shortly be commenced at Benghazi.

THE MINERAL WEALTH OF ALASKA.—The value of the mineral production of Alaska in 1911 is estimated at £4,500,000, of which £3,500,000 was of gold. The gold production in 1910 amounted to £3,250,000. The copper output is estimated at

Hosted by Google

23,000,000 pounds in 1911, against 4,200,000 in 1910. Alaskan mines and quarries also produced silver, tin, coal, marble and gypsum, to an estimated value of £80,000, an increase of £40,000 over 1910. The total value of Alaska's mineral production since 1880, when mining first began, is in round numbers £42,000,000. Of this amount £40,000,000 represents gold, and copper £1,600,000, the mining of the latter metal having been begun about ten years ago. Aside from the increase of copper mining, the advance made in the development of gold-lode mines was the most encouraging feature of the year 1911. The most notable advances in lode mining were made in the Juncau, Valdez, Kenai Peninsula, Willow Creek, and Fairbanks districts. Dredge mining also made great progress, particularly in the Nome region. At the close of 1911 there were 465 miles of railway in the territory, compared with 371 miles in 1910. The most urgent need at present is for a railway to connect an open port on the Pacific with the Yukon Basin.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings, at 8 o'clock:—

February 21.—Frank Warner, "The British Silk Industry and its Development since 1903." Sir George Birdwood, K.C.I.E., C.S.I., M.D., LL.D., will preside.

February 28.—H. A. Roberts, M.A., Secretary of the Cambridge University Appointments Board, "Education in Science as a Preparation for Industrial Work." Principal Sir Henry A. Miers, M.A., D.Sc., F.R.S., will preside.

March 6.—T. Thorne Baker, "Some Modern Problems of Illumination: The Measurement and Comparison of Light Sources."

March 13.—Professor Ernest A. Gardner, M.A., "Greek Sculpture."

March 20.—F. Martin Duncan, "The Work of the Marine Biological Association." P. Chalmers Mitchell, D.Sc., LL.D., F.R.S., will preside.

March 27.—Theodore E. Salvesen, "The Whaling Industry of To-day."

Indian Section.

Thursday afternoons, at 4.30 o'clock:—

March 14.—E. A. Gait, I.C.S., C.I.E., Census Commissioner for India, "The Indian Census of 1911."

May 16.—Neville Priestley, Managing Director, South Indian Railway, "Indian Railways."

Colonial Section.

Tuesday afternoons, at 4.30 o'clock:—

May 7.—Alan Burgoyne, M.P., "Colonial Vine Culture."

May 21.—The Hon. J. G. Jenkins, "Australian Railways."

Cantor Lectures.

Monday evenings, at 8 o'clock:—

Loudon M. Douglas, F.R.S.E., "The Meat Industry." Three Lectures.

Syllabus.

Lecture III.—February 19.—The Pig and its Products.

Luther Hooper, "The Loom and Spindle: Past, Present, and Future." Three Lectures.

Syllabus.

Lecture I.—February 26.—*Primitive Looms and Spindles: Prehistoric, Ancient, and Modern.*—The loom and spindle almost universal—Modern spinning and weaving machinery all constructed on ancient principles—Traces of prehistoric spinning and weaving—Simplicity of primitive tools and appliances—The simple textures of prehistoric cloth—The simplest loom and its essential parts—Modern and prehistoric webs compared—The spindle of all time—Advantages of *distaff and spindle* spinning—Modern distaff spinners—Spinning wheels—Peculiarity of primitive and ancient European looms—Greek and Egyptian methods of weaving—Egyptian, Persian, Roman, Brussels, and modern French and English tapestries.

Lecture II.—March 4.—*The Handloom for Automatic Weaving, Plain and Ornamental, and the Modern Spindle.*—Leonardo da Vinci's sketch of the spinning wheel *flier* and *bobbin* attachment—Its general adoption in Europe for hand spinning—Varieties of the motion developed—Inventors of spinning machinery—Hargreave's *Jenny*, Arkwright's *Waterframe*, Crompton's *Mule*, and others—Weaving in ancient China—Horizontal looms—Indian looms—Old English and other looms for silk weaving—Chinese silk loom—Invention of satin weaving—Looms for weaving small designs—Double *harness* weaving—Long- and short-eyed *leashes*—Chinese *draw-loom*—The *comber board*, its great importance—The *pulley box*—The tail of the loom—The *simple*—The *tie-up* of the design—The *divided* comber board and other arrangements for *tissue* weaving—European draw-looms—Examples of draw-loom woven textiles of various periods.

Lecture III.—March 11.—*The Modern Loom for Plain and Ornamental Weaving and its Future Development.*—Eighteenth century inventions compared with those of earlier periods—The drawboy—The drawboy machine—The Jacquard machine or *draw-engine*—Kay's *fly shuttle*, its great utility and unexpected value—The first power-looms—Application of steam power to the loom—General adoption of the factory system in textile industries—Comparison of hand and power-looms as regards quality and speed of weaving—The effect of machine weaving on the workers—Defects of the power-loom—Electricity as applied to the loom—The loom of the future.

Noel Heaton, B.Sc., F.C.S., "Materials and Methods of Decorative Painting." Three Lectures.

March 18, 25, April 1.

Hosted by Google

HOWARD LECTURES.

Monday evenings, at 8 o'clock :—

CAPTAIN H. R. SANKEY, R.E., M.Inst.C.E., "Heavy Oil Engines." Four Lectures.

April 29, May 6, 13, 20.

Dates to be hereafter announced :—

CHARLES C. ALLOM, "The Development of Artistic Skill in the Applied Arts."

ERNEST KILBURN SCOTT, Assoc.M.Inst.C.E., M.I.E.E., "The Manufacture of Nitrates from the Atmosphere."

E. D. MOREL, "British Rule in Nigeria."

GORDON CRAIG, "Art of the Theatre." MISS ELLEN TERRY will preside.

GEORGE FLETCHER, "Technical Education in Ireland."

MEETINGS FOR THE ENSUING WEEK.

MONDAY, FEBRUARY 19...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Mr. Loudon M. Douglas, "The Meat Industry." (Lecture III.—The Pig and its Products.)

Bibliographical, 20, Hanover-square, W., 5 p.m. Mr. W. W. Greg, "What is Bibliography?"

East India Association, Caxton Hall, Westminster, S.W., 4.30 p.m. Mr. S. S. Thorburn, "Peasant Scholarships *versus* Patchwork Compulsory Education for India."

British Architects, 9, Conduit-street, W., 8 p.m. Mr. E. Warren, "Collegiate Architecture."

Victoria Institute, 1, Robert-street, Adelphi, W.C., 4.30 p.m. Mr. S. T. Klein, "The Real Personality or Transcendental Ego."

TUESDAY, FEBRUARY 20...Royal Statistical, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5 p.m. 1. Mr. T. T. Williams, "The Rate of Discount and the Price of Consols." 2. Mr. R. A. Macdonald, "The Rate of Interest since 1844."

Illuminating Engineering Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C. Discussion on "Shoplighting," to be opened by Mr. N. W. Prangnell (Metropolitan Electric Supply Co.) and Mr. A. E. Broadberry (Tottenham Gas Co.).

Royal Institution, Albemarle-street, W., 3 p.m. Professor W. Bateson, "The Study of Genetics." (Lecture VI.)

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Mr. F. Shelford, "Some Features of the West African Government Railways."

Zoological, Regent's Park, N.W., 8.30 p.m. 1. Dr. A. T. Masterman, "Notes on Age-determination in Scales of Salmonoids, with special reference to Wye Salmon." 2. Dr. H. Lyster Jameson, "Studies on Pearl-Oysters. I.—The Structure of the Shell and Pearls of the Ceylon Pearl-Oyster (*Margaritifera vulgaris* Schumacher), with an examination of the Cestode Theory of Pearl Production." 3. Mr. Robert Shelford, "Mimicry amongst the Blattidæ; with a Revision of the Genus *Prosoplecta* Sauss." 4. The Rev. O. Pickard-Cambridge, "Contributions to the Knowledge of the Spiders and other Arachnids of Switzerland."

WEDNESDAY, FEBRUARY 21...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. Frank Warner, "The itish Silk Industry and its Development since 1903."

Microscopical, 20, Hanover-square, W., 8 p.m. 1. Mr. C. F. Rousselet, "Fourth List of New Species of Rotifera since 1889." 2. Mr. E. J. Spitta, "On the Colouring of Lantern Slides."

United Service Institution, Whitehall, S.W., 3 p.m. Lieutenant-Colonel J. Campbell, "Infantry in Battle."

Royal Society of Literature, 20, Hanover-square, W., 4 p.m. Professor Henry Newbolt, "Poetry and Rhythm."

London School of Economics and Political Science, Clare Market, Kingsway, W.C., 5 p.m. Mr. Ben H. Morgan, "The Trade, Industry, and Finance of the British Empire." (Lecture III.) 7.15 p.m. Mr. H. C. Cameron, "The Economics of the Refrigerated Food Supply of Great Britain, with Special Reference to Distribution." (Lecture I.)

THURSDAY, FEBRUARY 22...Royal, Burlington House, W., 4.30 p.m.

Antiquaries, Burlington House, W., 8.30 p.m.

Royal Institution, Albemarle-street, W., 3 p.m. Mr. M. H. Spielmann, "The Portraiture of Shakespeare." (Lecture II.)

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Mr. W. C. F. Anderson, "The Geography of Hell, Pictorial and Poetical."

Electrical Engineers, Victoria-embankment, W.C., 8 p.m. Messrs. J. C. Macfarlane and H. Burge, "The Supply and Transmission of Power in Self-contained Road Vehicles and Locomotives."

China Society, Caxton Hall, Westminster, S.W., 8.30 p.m. Mr. E. C. Wilton, "With the Mission to Lhasa."

FRIDAY, FEBRUARY 23...Royal Institution, Albemarle-street, W., 9 p.m. Mr. G. R. B. Elphinstone, "The Gyrostatic Compass and Practical Applications of Gyrostats."

Civil Engineers, 25, Great George-street, S.W., 8 p.m. (Students' Meeting.) Mr. W. T. Douglass, "Works for the Prevention of Coast Erosion." (Vernon-Harcourt Lecture II.)

Physical, Imperial College of Science, South Kensington, S.W., 5 p.m.

SATURDAY, FEBRUARY 24...Royal Institution, Albemarle-street, W., 3 p.m. Professor Sir J. J. Thomson, "Molecular Physics." (Lecture I.)

North-East Coast Institute of Engineers and Shipbuilders, Newcastle-on-Tyne, 7.30 p.m. (Graduates' Section.) Mr. A. P. Patterson, "Vessels for Carrying Oil in Bulk."

Correction.—Lieutenant-Colonel Sir Charles Bedford, I.M.S., asks that the following corrections may be made in the figures given in the report of his remarks in the discussion on the paper, "The Influence of Ozone in Ventilation," by Drs. Leonard Hill, F.R.S., and Martin Flack (see *Journal* of February 9th, 1912, p. 352, col. 2):—In the sentence "Hartley found that $\frac{1}{50000}$th part of ozone was perceptible to the senses," for the fraction "$\frac{1}{50000}$th" read "$\frac{1}{2500000}$th." In the sentence "The ordinary proportion of ozone in air was something like $\frac{1}{100000}$th of the volume of air, and it had been found that $\frac{1}{1100}$th to $\frac{1}{1200}$th of a milligram of ozone per litre constituted, for certain therapeutic purposes, an innocuous dose," for the fraction "$\frac{1}{100000}$th" read "$\frac{1}{70000}$th"; for the fraction "$\frac{1}{1100}$th" read "$\frac{11}{100}$ths"; and for the fraction "$\frac{1}{1200}$th" read "$\frac{12}{100}$ths." Sir Charles Bedford further adds that the figures given were not obtained by him, but were quoted from various writers on the subject.

No. 3,092. VOL. LX.

FRIDAY, FEBRUARY 23, 1912.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, FEBRUARY 26th, 8 p.m. (Cantor Lecture.) LUTHER HOOPER, "The Loom and Spindle: Past, Present, and Future." (Lecture I.)

WEDNESDAY, FEBRUARY 28th, 8 p.m. (Ordinary Meeting.) H. A. ROBERTS, M.A., Secretary of the Cambridge University Appointments Board, "Education in Science as a Preparation for Industrial Work." SIR HENRY A MIERS, M.A., D.Sc., F.R.S., Principal of the University of London, will preside.

Further details of the Society's meetings will be found at the end of this number.

CANTOR LECTURE ON "THE MEAT INDUSTRY."

On Monday evening, February 19th, MR. LOUDON M. DOUGLAS, F.R.S.E., delivered the third and final lecture of his course on "The Meat Industry."

On the motion of the Chairman, COLONEL SIR JOHN SMITH YOUNG, C.V.O., a vote of thanks was accorded to the lecturer for his interesting course.

The lectures will be published in the *Journal* during the summer recess.

CANTOR LECTURES ON "THE CARBONISATION OF COAL."

The Cantor Lectures on "The Carbonisation of Coal," by Professor Vivian B. Lewes, have been reprinted from the *Journal*, and the pamphlets (price one shilling) can be obtained on application to the Secretary, Royal Society of Arts, John Street, Adelphi, London, W.C.

A full list of the Cantor Lectures which have been published separately, and are still on sale, can also be obtained on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

INDIAN SECTION.

A meeting of the Indian Section was held on Thursday, February 8th, 1912. SIR FREDERIC W. R. FRYER, K.C.S.I., formerly Lieutenant-Governor of Burma, in the chair.

THE CHAIRMAN, in introducing the reader of the paper, said it was hardly necessary for him to introduce Sir Thomas Holdich, because he was well known to everybody present either personally or by reputation, and by his writings. At the present moment the subject of the North-East Frontier of India was one of great prominence, partly in consequence of the occupation of Tibet by the Chinese, and by the pressure they had brought to bear on the tribes on the British side of the North-East Frontier, and partly in consequence of the Abor Expedition. He thought the members of the Society were very fortunate in being privileged to hear a paper from the author on the North-East Frontier of India, as he was an exceptional authority upon the question, and anything that he said was sure to be of very great interest.

The paper read was—

THE NORTH-EASTERN FRONTIER OF INDIA.

By COLONEL SIR THOMAS H. HOLDICH, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc.

So little do we hear in England of the North-Eastern Frontier of India that when the news came of the total annihilation of a mission to the Abors, few people knew who the Abors were, or what we had to do with them. And yet this remote corner of our Indian Empire possesses an interest, political and scientific, which is almost unique. Politically, it is here that the dividing line exists between the Chinese Empire and our own. Here is the hedge over which we may look, but which we may not pass; and here we may discern what the expansion of another great empire may effect in the matter of approach to our domains, and of control over

Hosted by Google

a horde of Mongoloid peoples who have direct relations with ourselves and whose goodwill as frontier neighbours we cannot ignore. The scientific interest covers so large a space that it is impossible to deal with more than a section of it in one short paper. In the first place it includes a geographical area where there are still many problems unsolved, in spite of the fact that we have a grasp of the main features of its conformation. Gradually, year by year, we have traced out the waterways of the great Asiatic rivers which enclose this butt-end of the Tibetan plateau land. We have traced them out on general lines, but we have not surveyed them. We know where they must be, but we have not always seen them, and we still have to learn their value in the great scheme of inter-communication which these valleys afford.

As a field of ethnographical study I can only compare this land of magnificent altitudes and grand natural features with the land of the Kafir in the far North-West. Here, again, is an inaccessible region which has become the last refuge of the flotsam and jetsam of aboriginal Asiatic humanity, driven further and further into the wilderness by the inexorable laws of advancing civilisation and the survival of the fittest. Call that miscellaneous agglomeration of the relics of ancient tribes on the North-East by what name you will—Indo-Chinese, Indo-Burmese, or Tibeto-Chinese—they are the modern representatives of Mongoloid races who have long ceased to have any place in the scale of human development of Asia, and who really ought to be carefully studied as original types, or at least as primitive forms of humanity, ere they pass away altogether from the world's great stage. Time after time has the attention of the Government of India been drawn to the necessity for systematic research in this fascinating field of inquiry, and more than one Orientalist has broken the ground for a comprehensive and systematic study of them hereafter (notably Colonel Waddell, of the Indian Medical Service), but so far the impossibility of free movement amongst the most obstinately hostile of these tribes has barred the way to further progress. But no thirst for scientific information would altogether justify such an expedition as that, for instance, which is now being carried through the Abor country; and without such expeditions we shall never learn the truth either geographical or ethnological. When we are actually brought into contact with these unruly and wholly irresponsible savages, it is through the absolute necessity of maintaining order on our borders and protecting our own people in their homesteads and plantations of the plains. Experience on the North-West Frontier has taught us that the only way to secure immunity from the raids and robberies of turbulent and independent tribespeople, who have little to lose and much to gain by brigandage and murder, is to walk through their country, to hunt out their strongholds, and, if possible, to get beyond and behind them. Where their back doors, as well as their front doors, are commanded trouble ceases, but it is not much of the North-East Frontier that can be secured in this way. We must also bear in mind that it is from the extremity of our North-Eastern Frontier that there extends eastwards and southwards the line of least resistance for future land connection with China and Burma.

So far as China is concerned we need trouble ourselves no further as to the value of that frontier line which the Chinese (as I will show you) have already made their own; but as regards Burma it is impossible to look to a long future without the conviction that India and Burma will eventually be linked by a railway which will render a complete command of all contiguous tribes a political necessity.

What do we know as the North-East Frontier of India? Of what does it consist? Just as the Indus, with the rising steps of a mountain system leading up to a plateau land beyond it, marks the main feature of our North-Western Frontier, so does the Brahmaputra, from its outflow through the deep gorges of the hills north of Sadiya till it turns southward into the plains of Bengal, combined with the broken ridges of the Himalayan rampart to the north, embrace the great physical area of the North-East Frontier. These two magnificent rivers—the Indus and the Brahmaputra—start from the same cradle of the Tibetan mountains, and, sweeping outward in deep grooves to the north-west and south-east, they enclose within their mighty arms the whole of the Himalayan mountain system as now recognised geographically.

Beyond the Indus to the north-west we call the mountains trans-Himalayan. Beyond the Brahmaputra to the north-east (the country with which we shall deal presently) we have an extension of the great uplift of Tibet, scored with deep-cut waterways and seamed with magnificent ranges and ridges, which have yet to be adjusted in our maps. The valley of the Brahmaputra is, speaking broadly, the province of Assam, the province which we know as the home of many a profitable plantation, and a

Hosted by Google

population both native and European lying more apart from the social and commercial life of the rest of India than any other province in the Indian Empire.

Through this valley of agricultural wealth flows the stately river for 450 miles in a broad and usually placid sheet of water, exhibiting every variety of river action in the formation and destruction of land on a truly gigantic scale. Here the silt washed down from the Himalayas accumulates in masses of mud, extending the banks or forming into new islets on the basis of some casual obstruction; there the river breaks away from recognised channels, and wanders with uncontrollable irresponsibility into new waterways, rendering navigation uncertain and dangerous, and forming loops which almost rival the main stream in volume. As with the Indus, so with the Brahmaputra, constant accretions of silt on its bed have gradually raised its level, so that the bordering strips of swamps and morass are constantly submerged; but beyond them again the ground gradually rises into gentle grades to the foot-hills of the mountains on either side. With the rugged plateaux and broken hills of the mountain systems south of the Brahmaputra we have nothing to do just now. These are the homes of the Kasia and Garo tribes, who may rightly be classed with North-East Frontier peoples; but we shall have quite enough to do if we confine our immediate interests to the Nagas, who occupy the hills south of the river near to the Burmese frontier, and to all the troublesome folk who people the northern hills of the Assam valley to the east of Bhutan: the Akas, Daflas, Abors, Miris, and Mishmis (not to trouble you with any but the best known tribal names). It is because we know so little about these people that I desire to draw your particular attention to them, for these are the people and this is the land which constitute our North-East Frontier. The physical character of this borderland, however, varies little, and if we take Bhutan as typical we may very safely infer that the general character of the Bhutan conformation is more or less repeated throughout the south-eastern edge of the Tibetan highland to the east of it.

Approaching the hills from the south one is immediately faced with the dense forest growth of the Tarai, interspersed here and there with vast spaces of reedy flats, where the grass grows twenty feet high and the track of the buffalo or elephant affords the only possible means of exploration. Many a weary day have I spent in the endeavour to outflank these deadly grass jungles in order to carry a connected line of surveying past them. They are impassable without the assistance of an elephant. Where grass ceases forest commences, and although these forests do not exhibit the magnificent array of creepers and the wealth of palms and flowering plants which distinguishes Central and South American forests, they glory in the same feature of gigantic trees towering hundreds of feet above one's head, well supported by a force of bamboo thickets and jungle of minor growth, which it is absolutely impossible to penetrate. Rapid movement through these lower forests is impossible except on the rare occasions when one strikes a native footpath. As the greasy, uneven, rain-sodden track winds uncomfortably up the lower spurs to higher altitudes the character of the forest changes somewhat. The trees are of more moderate dimensions; only the bamboo increases, and at intervals tree-ferns and other easily recognisable sub-tropical plants occur, crowding and drooping over the mountain streams and decorating cascades. Animated nature asserts itself in the form of innumerable leeches, and these ubiquitous pests can penetrate anything except a stoutly-twisted putti. Bamboos specially crowd the valleys, and at 6,000 feet or so you may have the luck to look down from a height into the blue depths of a gully, where a heavy fall of snow has, perchance, taken up the curving threads of the bending bamboo, and woven a pattern of white lace over the hillsides as lovely as the silvery fall of an ice-bound cascade. At 4,000 feet or so we find the first clusters of wood-built hamlets, the early signs of permanent habitation. So far we have been climbing up the first steps of the gigantic natural staircase which leads to the great Asian plateauland. If we regard the Himalayan system as forming the wrinkled and corrugated edge of the Tibetan tableland, and presenting, in their original and primitive form, a succession of parallel barriers, or steps, leading from the plains to the plateau, we should expect here and there to encounter certain landings, or flats, dividing, as it were, successive flights of stairs till we reach the top. This is practically what happens along the whole line of the Eastern Frontier, although the conformation is by no means as well marked as it is in the far North-West. The original great scheme of Nature in thus fashioning the approach to the roof of the world is recognisable from the Indus to the Brahmaputra, but in the matter of physical aspect, due to the difference of climate, no greater contrast can be conceived than that

Hosted by Google

which exists between the barren and rock-bound and glacier-split barriers of the North-West and the more or less rounded and jungle-covered slopes of the North-East. Up to the altitude of 5,000 ft. or 6,000 ft. there is no break in the strength of the forest solitudes. Above that altitude, where human habitations are met with, the forest thins and varies in character. One wanders through an atmosphere of almost everlasting mist and cloud, amidst a weird array of gaunt, moss-covered trees with long grey beard-like parasites drooping and dripping rain-showers as they are gently stirred by the wind. It is beyond this again that we encounter the first rolling uplands with wide valleys and brawling streams, sweet grass-covered slopes covered with the glory of purple and white rhododendron, and clothed with flowers as with a Persian carpet. This is, indeed, a most lovely country, the last landing, as it were, on the Himalayan staircase before reaching the stern wide solitudes of Tibet. Physically, Bhutan is as much Bhot (or Tibet) as is all the country east of it bordering the Assam valley on the north. Politically and socially it is distinct. British India, as represented by the Assam valley, is bordered on the north by Tibet throughout. We recognise no distinct borderland of independent tribes, as we do on the North-West, when once we are east of Bhutan. But where Tibetan (in other words, Chinese) authority and influence end, and where British authority begins, we do not know. What has happened is this. The primitive Mongoloid inhabitants of this part of Asia, crushed in between the two gigantic and expansive forces of advancing Tibetan and Chinese civilisation, have been forced into the narrow spaces of the roughest and most inaccessible hills which border Assam, further advance south being barred against them by Indian occupation. I have spoken of Tibetan civilisation as a coercive power distinct from the Chinese, because in the past, when these great movements of Asiatic humanity were in progress, it was so. We hardly give sufficient credit to Tibet for its once dominant position in the world of Asiatic policy. Tibet has sent conquering armies into China and into India. Tibet has dictated terms to the Chinese Emperor, and, until its vigorous nationality was destroyed by the malignant growth of a debased and almost demoniacal form of Buddhism, Tibet stood as high morally in the roll of Asiatic nations as it stood physically. A reference to one concrete form of Tibetan civilisation in contrast to that of the savage Mongoloid tribes of the Assamese frontier will, perhaps, illustrate better than any other method the fact that, although we may write the word Tibet across these border hills north of the Brahmaputra, and to the east of Bhutan, we have little or nothing that is Tibetan to deal with when once we enter them.

From the magnificent series of photographs collected by the greatest living authority on Bhutan, Mr. Claude White, let me show you what Bhutan can rise to in the matter of architecture. For strength and utility, adaptability to site, and complete harmony with environments certain Bhutanese buildings may almost compare with the mediæval architecture of Europe, whilst in detail of decoration they are, of course, unique. It is not necessary to go to Lhasa to convince oneself that the Tibetan race belongs to the building races of the world.

We will now turn to the extreme north-eastern corner of our frontier, that point of the Assamese wedge which, in the present state of Indian affairs, is the part which matters most. The end of the Assam railway system is on the left bank of the Brahmaputra River, opposite Sadiya, which may be considered our most advanced station. There is a branch line from Makum junction to Margharita which is important. Some fifteen or twenty miles below Sadiya is the actual point where the Brahmaputra or Tsang-Po of Tibet, after issuing from the hills into the plains of Assam, takes its south-westerly bend; consequently Sadiya is on an affluent of the Brahmaputra, which affluent has formerly been recognised as the real source of the great river, and is called the Lohit Brahmaputra still. In order to have a proper understanding of the geographical problem of this extremity of the Indian Empire, it would be well first of all to take careful note of the names of the various rivers which unite there to form the volume of the great stream which slides so majestically through the valley of Assam, because these names bear a most unfortunate likeness to each other, and may easily be confused.

We know now that the main stream of the Brahmaputra comes from Tibet, breaking its way through Himalayan barriers, but until it has actually passed these barriers and reached the centre of the valley it is known as the Dihang. It is on the borders of the Dihang that the Abors live of whom we shall have something to say presently. Eastward of the Dihang is the Dibong, which drains from north to south through an unexplored corner of Tibet, although its lower reaches have been mapped by

Hosted by Google

Woodthorpe and Ward. Its chief affluent is the Ikthan or Ithan. Next comes the lineal extension of the Brahmaputra, the Lohit Brahmaputra, on which stands Sadiya, leading directly to China. Not a hundred miles from Sadiya, on the Lohit, is the village of Rima, and at Rima the Chinese have recently established a frontier post. From Rima the road to China strikes off north-east over a series of high passes to Batang, which now must be reckoned as a Chinese town rather than Tibetan, and where, I believe, we may find the most advanced of the inland mission stations in western China. The river itself leads northward from Rima to the Tibetan plateau and Lhasa. From Batang to Rima and from Rima to Lhasa, the route has been traversed by that well-known native explorer who now lives in retirement as Krishna. From Sadiya to Rima various attempts to map the river have been made, and it is in this connection that the name of Needham is most prominent. It is impossible within the narrow limits of a paper like this to do justice to the names and memories of all the gallant officers and gentlemen who have distinguished themselves on the North-Eastern Frontier, but in the political field the name of Needham, political officer at Sadiya, stands out as does that of Woodthorpe in the field of exploration and survey. What Needham does not know about the North-Eastern Frontier certainly no one else knows. His connection with the wild, but not totally irreclaimable, savages of that remote corner of our Empire is one of the romances of the North-East. He nearly reached Rima, quite near enough to fix its position relatively to Sadiya. Turning south from the Lohit, we arrive at the Dihing which points south-eastwards to the foothills of the Patkoi range and the gateways of northern Burma. Thus we have the Dihang, the Dibong, and the Dihing in close juxtaposition, and uncomfortably similar in sound, all their names probably being derived from one and the same primitive native equivalent for the word "river."

It is with these waterways of the Brahmaputra, radiating as it were from the apex of the Assam valley, that we have chiefly to concern ourselves.

The Dihang, which is really the main stream of the river, connecting in one continuous channel the Tzanpo, of the Lhasa system, with the Brahmaputra of the Assam basin, concerns us chiefly, for it is the valley of the Dihang that affords the most obvious geographical opportunity for a direct connection with the most highly-developed provinces of Tibet, and it is in the wilderness of forest-clad mountains which enclose the Dihang that the Abors dwell, the people who have so persistently resisted all efforts to effect a passage through their narrow territory, and who have lately signalised their determined opposition to the interchange of friendly communication by the disgraceful treachery which marked the murder of Mr. Williamson and of his whole party. The opposition is easily explained and is perhaps natural, but the treachery which withdrew that opposition for a time for the purpose of entangling their friendly visitors in a position from which there could be no escape will, we trust, be properly punished. Westward of the Abors the hill country is occupied by the Miris, who extend into the forest-covered flats of the plains below the hills. The flat forest (or Tarai, as it is locally called) between the Dihang and Dibong, is practically uninhabited. Immediately west of the Dihang the hills are the home of the Passi-Meyong Abors; the Pangi Abors come between the Dihang and the Yamne; and the Bor Abors (Bor means "great") hold the hills from the Yamne to the Dibong. These three sections or clans of the Abor tribe are thus all of them people of the hills; the Miris, to the westward of them, are found both in the hills and the plains; and the Mishmis, a most important tribe that cannot be overlooked, occupy the basin of the Lohit Brahmaputra, to the east. We need not trouble ourselves about any other of these Mongoloid tribes at present. In general physique they are all alike, the Abors, perhaps, being the finest race. In tribal customs they differ considerably in detail, but in the outer barbarism of their methods, their savage lust for bloodshed, and their general indifference to the ordinary and natural laws of chivalry, even amongst savages, when dealing with women and children, there is little to differentiate them from the naked head-hunting Nagas of the southern Assam hills. Just to refer shortly to the details of the expedition which is now being undertaken against the Abors, you will observe that the base of it is at Kobo, near the junction of the Dihang and Brahmaputra. From Kobo one column has followed the line of the Dihang to Pasi Ghat, at which point the river debouches from the hills. A second column made its way westward to deal with the Pasi Meyong Abors, entering the hills somewhere near peak 2835 on the map, ultimately joining number one column at Kebang. It is with number one column that the interest of the expedition chiefly lies, for it

Hosted by Google

is in connection with the operations of this column that we shall finally learn whatever geographical secrets there may yet be to be learned about that section of the Brahmaputra River between Tibet and Assam which has never yet been surveyed, but which has been explored both from Tibet and from Assam, so that there is not much of it about which we can say we know absolutely nothing. The story of its exploration from Tibet is one of the romances of the Indian Survey Department.

Kinthup (or "K.-P.," as he is known in the confidential archives of the India Office) was a native of Sikkim, and one of the native explorers of the Indian Survey. In the year 1880 he went forth armed with certain instruments and some careful instructions to trace the Brahmaputra from Tibet to Assam. He travelled with a Chinese lama, also an agent of the Survey Department, a doubtful sort of companion, who was the originator of all his troubles. Making their way by routes previously explored, they arrived in due time at Gyala Sindong, near the point on the river where it bends sharply from a north-easterly to a south-easterly channel. So far there was no great difficulty, the route lying on the right or southern bank of the river. With the bend there occurs an abrupt narrowing of the valley caused by the enclosing mountains which closely grip the river for some five and twenty miles, producing a series of rapids and falls. It is possible, however, to follow the left bank of the river fairly closely to a point about five miles above the principal falls (Sindi Chogyal), whilst from a point two miles below these falls there is a well-trodden route passing from village to village till it reaches the market-town of Miri Padam. On the right bank of the river there are also tracks, and it is to be noted that the capital of the district, Pema Koichung, is not far above the falls connecting the routes on either side; but it is clear that there is no route on either side which follows the stream closely past these falls. Below them there are routes or tracks on both banks passing through villages and cultivation, and presenting, apparently, no great difficulties to travellers. Kinthup's description of the valley, its cultivation (which includes rice, cotton, and fruit), its monasteries and sacred places, and the wild and savage Abors of the lower reaches is deeply interesting. The roads are mere tracks, rising over successive spurs and dropping again into the flats on the river border. Clearly we must look to two sections of the valley to account for the fall of the river from the Tibetan highlands (say 11,000 ft.) to the flats of Assam (say, 500 ft.), and these two sections are the rapids and waterfalls of the Gyala Sindong gorge and the final grip of the mountains below Kebang, that gateway of the hills which makes the advance of our force under General Bower a work of such supreme difficulty. Kinthup got no further towards Assam than Onlet, above Miri Padam, but his account of the generally open and easy nature of the valley between the falls of Sindong and Kebang is fully supported by the two Gurkha surveyors who made their way under Mr. Needham's direction in the spring of 1901 to Kebang by the right bank of the Dihang, and were there met by the determined opposition of the Pasi Minyongs, who blocked any further exploration most effectually. They maintain that the route from Kebang to Gyala Sindong (which they said they could see in the distance on a clear day) was absurdly easy compared to that which they had surmounted. They speak, indeed, of country "open and undulating," and the distance only ten stages. The falls are very sacred and the bourne of many a devout pilgrimage. Clouds of misty spray rise into the clear atmosphere above them, and a rainbow ever spans the valley. The scenery is magnificent. A dense sub-tropical jungle, rich with every variety of tree-fern and bamboo, reaches up the hill-sides to the limits of more open spacing, and a more stunted growth of rhododendron and oak. Above them are protruding glaciers and granite peaks, and towering above all the eternal snows and the everlasting silence of the ice-fields. I should like to tell you more fully about Kinthup, but time fails me—how he was sold into slavery and served his time under a Tibetan taskmaster; then, escaping, he was hunted through the valleys, claimed the protection of a monastery, and was again bought as a slave, and, escaping again, dug out his hidden instruments, and with no thought of turning back, set his face steadily to carry out the instructions of his master, Captain Harman. Finally he found a cave, and therein he completed the cutting and marking of certain logs, which were to float down the river to tell Captain Harman, who was on the watch in Assam, that the river where the logs started was one and the same with the Brahmaputra. Many a long day did the gallant Harman watch from his station for these wooden messengers bobbing along on the swirling tide of the great river—and at last he died there before they reached him. Kinthup knew nothing of this. He adopted the *rôle* of a pilgrim and made a fresh start. He

Hosted by Google

explored a new route from his monastery on the Brahmaputra to Lhasa; again returned by other ways on his original quest, reaching south as far as Onlet, where he was stopped by the pig-headed obstinacy of the Abors within sight of Miri Padam. Eventually he returned by Lhasa, and turned up at the headquarters of the Survey Department in India after four years of patient research and most extraordinary adventure. His reports have been verified once and again, but his mapping, under the uncertain conditions of his work, certainly left something to be desired. That something we shall learn from my old friend, General Bower, when he comes back from dealing with Williamson's murderers. The man who pioneered the first European track across Tibet from west to east is not the man to come back from this unmapped corner of our North-Eastern Frontier with his work half-finished. General Bower is a good soldier and sportsman, but before all things he is a sound geographer.

A notable expedition into the Abor country as far as Kebang was made by Colonel D. M. Lumsden in January, 1909. He was accompanied by the ill-fated Political Officer, Mr. Williamson, and by Mr. Jackman, of the American mission, who can talk the Abor language "like a native." On that occasion they were guided by the *gam*, or head man, of Kebang from Pasi Ghat, where they entered the Abor country, and their welcome at Kebang, if rough and rather embarrassing, was, at any rate, sound. Beyond Kebang, however, they could not proceed. The excuse made was the existence of tribal war between certain sections of the Abors, which would make travelling unsafe, and they were in a position to verify the statement as correct. A notable personage in the Gam of Ren met them at Kebang, and addressed the Abors publicly. It is probable that the negotiations which then passed between Williamson and this chief led to the subsequent fatal expedition, for it was apparently through the treachery of this chief that the party were massacred almost to a man. It is to Colonel Lumsden that I am indebted for the few photographs of the Abor community which we possess.

The Dibong River drains an important section of the Mishmi country lying east of the Abors. It has been traced and mapped for some twenty or thirty miles above its debouchment from the hills from Nizamghat by Woodthorpe and Ward, and the general conformation of the hill country overlooked corresponds with that already described as the lower basin of Dihang. It is essentially upland deeply rifted by narrow waterways. The hills range up to an altitude of 15,000 ft., and are all covered by dense tree jungle. This invariable feature of the North-East Frontier is due doubtless to the excessive moisture in the atmosphere of the wettest corner of India. The monotonous persistency of rainfall during nine or ten months of the year is an unpleasant feature of the climate, which accounts for much of the difficulty of movement about the country. Our friends on the Abor expedition are suffering much from this infliction. It may be noted that on the southern edge of the hills south of the Brahmaputra, where the inrush of cloud-bearing currents sweeping inwards from the Bay of Bengal first strikes the mountains, the rainfall is such as to constitute a world's record. It averages about 60ft. a year—enough to float a Dreadnought!

The Mishmi paths are steep and difficult, and there is nothing within the areas surveyed to indicate anything like the open and undulating valleys that we have been told to expect beyond Kebang on the Dihang (or Brahmaputra). What may be beyond the limits of Woodthorpe's exploration we have yet to learn. We shall find eventually, I have no doubt, that the belt of wild jungle-covered, and almost inaccessible, hills is backed by more open uplands, and that it is the fringe of the mountains and the gorges of the great rivers bursting through it that presents the chief difficulty to exploration. The Dibong, however, so far as we know, leads to no ultimate line of international communication, and is so far comparatively unimportant.

It is otherwise with the Lohit Brahmaputra (or Zayal Chu), which drains the Tibetan province of Zayal ere it reaches the Chinese frontier at Rima. Rima is less than a hundred miles from Sadiya, and the way thereto is beset with the usual amount of weary struggle with slippery rocky paths and jungle-covered hill. I have already said that Needham very nearly reached Rima from Sadiya, and that the explorer Krishna did actually reach Rima from the other side. From Rima he effected an important discovery by following up the Lohit northward to its source, reaching the Tibetan province of Kham, and ultimately Lhasa, by that route. The significance of Rima lies in the military post which China has recently planted here. We are politically on the edge of China wherever we touch Tibet or the wild tribes that border Tibet, but nowhere is the practical advance of that irrepressible nation so distinctly marked as at

Hosted by Google

Rima. What does it mean to us ? What is the real significance of this apparition of a yellow face looking over the border hedge into a corner of Assam ? I will not bore you by pointing out the reasons why, as a matter of military significance, it has no meaning at all ; I will merely indicate one at least of the conditions implied by that occupation. The Chinese do not dump down their military posts along their frontier without securing good and safe means of communication behind them ; so that we may well believe that the route followed by Krishna from Batang to Rima, crossing though it must a series of high passes, is a fairly useful road ; indeed, Krishna says it is. Batang, on the high road between Lhasa and China, is not more than 150 miles as the crow flies from Rima. At Batang, I believe, there is already a European mission station. I believe it because I know it was contemplated some time ago, and the missionaries are usually first on the field of practical geographical advance. The road thereto from Rima is very much longer than 150 miles—say 200—but it is evidently a sound route for purposes of military and commercial communication, and it is the straightest road to western China. The point of the position is this. If a Chinaman from Rima wished to explore Assam, we should not interfere with him. He might find a little difficulty with the Mishmis, but he would find none from us. We then have a right to demand reciprocity. If we, too, are prepared to take our chance with the Mishmis, who will not give trouble for long now that they are dominated from both sides, why should not we traverse the direct road to Batang and western China ? It has happened to me on another part of the Chinese frontier that the crossing of that frontier was immediately met by a hostile demonstration. I was politely, but unmistakably, made prisoner and marched back again. This, too, when I was actually assisting to determine a frontier in Chinese interests, so we may assume that there is not a prospect of our finding an open road beyond the Chinese door unless we insist on it as one of the conditions of Chinese occupation.

Yet another part of the North-Eastern Frontier must be touched upon. There are other ways of linking up India with China, which is one of the inevitable developments in the world's progress, than by taking the straight and narrow, but neck-breaking, path. We turn now to the Dihing. Not that the Dihing is in itself of any vast importance, but it points the way to Burma. We are now in the land of another primitive Mongoloid race, but a race possessing far more affinity with the Chinese. The Singphos are a section of the Indo-Burmese group who have in times past shown considerable activity and enterprise in enlarging their borders. They pushed across the intervening hills from Upper Burma into Assam, where they left their mark in the shape of the district name (Ahom or Asom), and where they are to be found still. Meanwhile a section of the irrepressible Nagas have thrust their way across the line of advance, and divide the Assamese Singphos from the Singphos of Burma. The Nagas, by the way, are not so irreclaimable as to be unaware of the value of the British rupee. They are the people from whom the leaders of the Abor expedition have recruited a most useful corps of carriers and jungle-cutters. They are a most interesting and bloodthirsty race, but time fails me to talk about them further.

The connecting routes between Upper Assam and Upper Burma have been thoroughly reconnoitred. There are three which offer possibilities for railway construction.

The story of the North-Eastern Frontier of India would be incomplete without a reference to that most important feature of it—the approaches and gateways to Burma. It is important for the reason that we might hereafter be sorely in need of a land route to Burma from India. Here we get back again to the old, old story of the command of the sea. We are never far from it in India ; and inasmuch as our hold on India is dependent thereon, you may probably object that if we lose that command we need trouble ourselves no further about a highway between India and Burma. But Britain still rules the waves, and there are other considerations, both political and commercial, which almost compel us to secure all the dominant power which such a right of way would give us. And it was with some such prompting as this, no doubt, that the Government of India wisely organised a series of surveying expeditions across the intervening hills, which should decide —and which have decided—where the iron way could best be carried. Of the three ways of getting to Burma from India, one is not an Assam route at all. This may be called the Aeng pass route. It follows the coast-line more or less from Chittagong southwards till it faces the easiest gap in the long extended mountain system of Arakan, which would allow of its divergence into the valley of the Irawadi, somewhere half-way between Rangoon and Mandalay. An expensive and difficult line. Then there is

Hosted by Google

the Manipur route, which leaves the Assam valley to the east of Gauhati and Shillong, and, after winding through the hills and visiting the small and independent state of Manipur, would land the traveller on the Irawadi, about half-way between Mandalay and Bhamo. This has certain military advantages, especially in matters touching Manipur, but, once again, it is expensive and difficult. Thirdly, there is the Hukong valley route, which, starting from near the head of the Assam valley, twists its way to the foot-hills of the dividing range of Patkoi, and then, negotiating that range by means of a prospective tunnel, drops into the small beginnings of the Hukong River, terminating on the Irawadi at Mogaung, to the north of Bhamo. This is the true North-East Frontier route, inasmuch as it would cost about half that which the Manipur route would cost, and is in every way the easiest to construct and to maintain. It is, therefore, the route which we may confidently expect will be ultimately adopted in that good time when India is free to spend money on frontier developments. The total distance from the railway head in Assam of this route is a little short of 300 miles, of which about half runs through the rough dividing hills between the Assam valley and the head of the Irawadi affluents, and the other half may be reckoned as a surface line. There is only one formidable dividing range parting the two great river systems at this point—the Patkoi—which runs to about 4,000 ft. in altitude. A tunnel at about 2,700 ft. would not be a difficult or very expensive construction, and the drop into the Hukong is simple. On the Assamese side of these dividing hills the jungle is very dense. It has been explored by several good geographers, amongst others by Needham and Woodthorpe. The latter followed the line of the Dihing. The universal feature of eastern frontier exploration is the terrific labour involved in cutting a way through the close-packed vegetation that is massed in the valleys and stiffens the hillsides of all hill slopes below 6,000 ft. in altitude. There is no getting away from it. A footway cut out of the solid jungle one year will be as if it had never existed by the end of the following rains; and it is only because Nature has so fitted man to his environment, that the untutored savages of this corner of the Empire are most skilful artists when it comes to jungle-clearing and load-carrying, that the European is able to grope his way through the rocky tracks at all. A notable journey was made by Mr. C. E. Young a few years ago from Yunnan, in China, to Sadiya, on the Brahmaputra, passing more or less closely along the Hukong valley route; but we have in the records of the Government Railway Survey in 1895 and 1896 so full an account of the route and its environment as to leave little to be added by subsequent explorers. The Intelligence Officer responsible for the Surveys on that special mission was Captain (now Sir Eric) Swayne, who has since proved his capacity for geographical exploration in Somaliland and elsewhere. Passing the Patkoi range we are in a district of somewhat different race affinities to those of the Assam valley. The Singphos and the Khamtis of the Assam valley are cognate peoples of the same Indo-Chinese stock. It is a matter of history that some hundred years ago the Khamtis crossed into Assam from Upper Burma, and have remained there ever since. The Singphos of the Hukong valley own many Assamese slaves, whom they treat well, on the whole, and who complain of nothing except the inevitable break-up of families under the conditions of slave commerce. The Singphos are hardly to be reckoned with as a martial race, and the little opposition that they might offer to a permanent European institution amongst them (such as a railway) would be prompted far more by their fear of a movement against slavery, entailing consequent loss to themselves, than by any active feeling of hostility to the European. Such at least was the opinion formed by the railway route explorers of fifteen years ago, and such seems to be the opinion of, perhaps, the greatest authority on Burmese affairs, Sir George Scott, to-day. He pointed out in an able paper, read before the Colonial Institute in December last, that what the fertile valleys of Upper Burma want is population, and that population with commercial development can only be introduced by communication with India.

Isolated railways and railway systems in the East lose half their value and significance if they are not projected with the ultimate idea of creating and developing commerce over large and favourable areas, however much they may be built to satisfy the claims of strategy and administration in the immediate future. "Shreds and patches" of railways, as Sir George Scott calls them, are only locally useful. They will soon disappear in China in favour of a national system, and then we shall be face to face with this curious anomaly. There will be one huge isolated system in India; another system not so huge, but equally isolated in Burma; and a third in China. Between these systems there will be no connecting link to bind

Hosted by Google

them to each other, or to bind India to Europe. Such a disjointment of the world's commercial interest cannot possibly last. There must be many here to-day who will live to see the linking up of Europe with India, and India with the remoter East, when it will be no longer necessary to take advantage of the enterprise of Russia in order to reach the shores of the Pacific from Western Europe; and the first link forged in the chain will probably be this of the Hukong valley.

One turns from the fascinating theme of the North-Eastern Frontier with something of regret. Doubtless there is more in the stirring atmosphere of the North-West to attract public attention, because it is there that we find the great bulwarks of India's defence, and it is there that we watch for the first shadow of those coming events which may affect the ultimate destinies of the whole British Empire; but, as a matter of sentiment, the call of the unknown and of the beautiful appeals more strongly from the North-East. It is not the large flat solitudes nor the cold craggy magnificence of icefields and snow-capped peaks of the North-West that first touch the chords of memory during the waking dreams of the shelved and antiquated Anglo-Indian official. Rather it is the butterflies and the birds, the wild beauty of Bhutan, or the deep, silent, tiger-haunted forests and savannahs of the mystical valley of the Brahmaputra.

DISCUSSION.

The Chairman (Sir Frederic Fryer), in opening the discussion, said that all present had listened with much interest to the graphic account of the North-Eastern Frontier given by the author, and they could now realise the nature of the country with which he had been dealing. The country was naturally one of great difficulty for surveyors. It was not only the physical features of the country that made it so difficult, but also the hostility of the inhabitants and the difficulties of transport. Those explorers who opened out such a country for the British people did so at very great risks, and incurred very considerable hardships. His own acquaintance with the North-East Frontier of India was principally confined to Burma. In Burma there had been several Boundary Commissions. In 1893 the boundary with Siam was delimited, and in 1895 the boundary of that country was delimited with France, which now was the Mekong River. There had been three years of boundary work by Commissions on the Chinese frontier; a considerable part of the Chinese boundary had been delimited, and the boundary had been marked out by cairns upon the spot. One gap was left in what was known as the Wa country, which was inhabited by a head-hunting and bloodthirsty tribe. When Sir George Scott, who was in charge of the British side of the Boundary Commission with China in 1900, was in the Wa country, three officers of the Commission went down to visit a market that was being held in a Wa village, and the natives fell upon them and killed two of the officers, Major Kiddle, of the Indian Medical Service, and Mr. Sutherland, of the Burma Commission. Mr. Lytton, who was the political officer of the Boundary Commission, very narrowly escaped with his life through the help of a Chinese sergeant. The Wa country had not yet been delimited, and though it was considered to fall within the British sphere of influence its administration had not yet been taken over. To take over the administration of a country inhabited by people like the Was was a very expensive thing. The country would have to be held by police posts; no revenue would be obtained, and for another thing it would be necessary to keep the Was in order. Beyond Bhamo the boundary was considered to be the watershed of the Salwin and the N'maikhah Rivers, and the Chinese had agreed that that should be considered the boundary. But it had never been actually delimited on the spot, and the Chinese were constantly trespassing across the border. In 1900, when the British Civil Officer was in that region on his winter tour of inspection, he was attacked by a large party of armed Chinamen. Fortunately he had an escort of seventy Ghurka police with him, and the Chinese had cause deeply to regret their boldness. Those sections of the frontier ought, no doubt, to be delimited. Although it was natural to suppose that the Chinese were already sufficiently occupied by their own internal troubles, as a matter of fact they were steadily encroaching on the British frontier; and unless the frontier was actually delimited, and this country was prepared to hold it in some force, the Chinese would always trespass across it. So far as the frontier actually delimited went, they observed it very well, and the Chinese officials met the British officials every year in the cold weather to settle any outstanding disputes. The great difficulty was to keep the tribesmen on the British side from attacking the tribesmen on the Chinese side, and *vice versa;* but any such cases were now dealt with by a joint commission of officers from both sides of the border, and so far things had worked very smoothly. With regard to the question of communication with India by railway, he believed that a line through the Hukong Valley would, as the author stated, be very easily made. The country was quite simple, and there were no very great natural obstacles. A proposal had been made to construct a line to T'êng-yüeh. A line could easily be made to T'êng-yüeh, but he had always understood the difficulty was to carry the line beyond that place. Engineers, however, could overcome all kinds of obstacles, and no doubt it would be possible for them to carry the line even beyond T'êng-yüeh; and there were, no

Hosted by Google

doubt, other directions in which a railway might be still more easily made.

Colonel Sir Eric Swayne, K.C.M.G., C.B. (Governor of British Honduras), said that whilst listening to the paper his memory had gone back to sixteen years ago, when he travelled through the country to which the author had referred. The question of the railway was one which had a very tangible interest to a large number of those present. Personally, he believed a railway would have to be made some day. Speaking only of the railway going eastward from Assam into Burma, there were, in the Hukong Valley, some 1,200 to 1,500 square miles of very fertile land covered with forests, but there was hardly any population there. A railway was required to bring a population and develop the country. It was a rubber-producing country, the rubber being obtained from the big rubber trees, and great quantities of rubber had been exported during the last thirty or forty years, both into Assam on the one side and Burma on the other. Chinese traders came with Burmans from the side of Burma and penetrated right up to the Patkoi range, made their advances to the local people, who gathered the rubber and floated it down on rafts into Burma, or else they carried it across the Patkoi range and sold it in the Dibrugarh market. When he went up to the Patkoi range, canoes had to be employed to carry the party up the streams, while subsequently rations were carried on the backs of elephants through tunnels in the forest up to the foot of the Patkoi range, where Naga coolies were obtained. From the Patkoi range a splendid view was obtained over the Assam valley, right up the headwaters of the Brahmaputra, the whole range of the Himalayas being seen in the distance. In looking down upon the country in that way the whole of Assam was spread out before the traveller like a map. The plains were covered with dark forests, and the line of each river was very clearly marked, winding in a white band across the plains. The rivers were full of fish, and the place was a true fisherman's paradise. In one hour he caught 80 pounds of mahseer, consisting of 30, 20 and 10 pounders. The fish was of a good fighting kind, and he could strongly recommend the sport to anyone who was a true fisherman. Unfortunately, while he was travelling in the country, the coolies accompanying the party contracted cholera to start with, and later on scurvy and dysentery. A great many of the men were lost in that way, and the camps were marked by the graves of the men who were left behind. The jungles were very thick, it being necessary to cut their way through them, and it was also necessary sometimes to make bridges over the rivers. The coolies were excellent men for that kind of work. In many cases the party preferred to march down the river up to their waists in water, rather than go over the thick jungle-covered hills, on which it was only possible to march two or three miles a day. When the Hukong valley proper was reached everything was plain sailing. If a railway was built it would be absolutely necessary for the British to control the tribes in the Hukong valley. As far as he saw, there would be no difficulty in doing that, the tribes being well disposed towards us. The only difficulty that would arise would be occasioned by the slave question. Domestic slavery existed in the country. The slaves were well treated, but hardship existed in that they were liable to be sold to other masters, so that mothers were separated from their children. The slaves were well fed, but any excess of zeal on their part did not make for their own good, but the benefit of it went to the masters. If a railway was made, that matter would have to be taken in hand, but he hoped that it would be done very gradually, and that nothing drastic would take place. Probably it would be wiser to adopt a system similar to that adopted in Zanzibar, by means of which domestic slavery would automatically cease as time went on. If the slavery question was properly dealt with, no trouble would be experienced in administering the Hukong valley. The valley itself was very rich. It possessed amber mines, the amber being dug out of pits; while on the borders of the valley, towards Burma, there were jade and ruby mines. His party came across huts in the Hukong valley, on the banks of rivers, which contained wooden dishes with which the natives collected gold. A regular practice was not made of working the gold, but when there was nothing to be done in the fields the natives went to the rivers and washed up whatever gold had been brought down by the floods. Sometimes the more energetic went up to the headwaters of the river, where the sands had collected, and returned with quills full of gold. The country might, he thought, develop into a splendid rubber-producing property, and, taking it all round, it was a country which England could not afford to neglect.

Sir James George Scott, K.C.I.E. (late Superintendent, Southern Shan States), said the author was a great authority on the North-West Frontier of India, and his book, "The Gates of India," was most charming reading. He hoped now Sir Thomas Holdich had gone a little towards the north-east, he would go farther still and write a book on the whole North-East Frontier. In order to tempt the author to examine the North-East Frontier, he wished to say that there were some gates there already, although they were not such gates as tempted Alexander to come in from the West with the Greeks. Although they were called gates, possibly the average person would call them trap-doors, or manhole doors, or attic windows. When the question arose of delimiting the Burma frontier, the Chinese adviser to the Burmese Government discovered in the T'êng-yüeh annals that there were seven gates all named, and they naturally seemed to concern the frontier very seriously. A British party, therefore, went out to find those gates, but they discovered they were just as difficult to identify as the writer of the letters of Junius. They travelled in a country quite as nasty as some of that shown in the

photographs; they did a lot of Alpine climbing in a sort of palm-house temperature; they cut down a very great deal of jungle, and they took down the sworn depositions of a number of imaginative headmen. At first they thought that the leeches were the most disagreeable feature of the country, but before they had gone far they came to the conclusion that the blood-blister flies were still worse. The whole winter season was spent in the hills, and when they got back to headquarters the only thing they were quite certain about was that all men were liars. The Chinese also knew that there were the seven frontier gates to which he referred. The Tsung-li Yamen sent a telegram to T'êng-yüeh to say: "The frontier with Burma is about to be delimited; there are seven frontier gates; see that those gates are found." The Chinese at T'êng-yüeh knew nothing about them, but they sent out orders to all the headmen and said, "There are seven gates; you must put them in order; the Board of Punishments will see about it if you don't." Therefore, in the businesslike way of all Chinamen, and people under Chinese orders, they proceeded to go to the farthest point to the south and the south-west where they could go without getting into trouble with the hill tribesmen, and proceeded to build seven gates, which were afterwards pointed out to the Chinese Commissioners when they visited the place. Their position was duly noted, but the frontier which was eventually laid down went near none of those gates at all. Their only use was that they pointed out the limit to which the Chinese could extend their authority. The people along the frontier were mostly Kachins, who were really the same people as the Singphos. Their own name for themselves in fact was Chingpaw. The author had stated that the Singpho were not a martial people. They must have deteriorated from the main body of the race, because although a Kachin might not be called a warlike man, he could not at any rate be called an effeminate or a degenerate. Their chief occupation for many years was stealing other people's cattle, which they did with quite as much enthusiasm as the Johnsons and the Jardines did on the North British frontier. The Singpho were mixed up with a number of other people. Photographs had been shown of the Lissu, who, the author had led them to believe, were the only people who possessed crossbows, but that was by no means the case. There were quite a number of tribes a long way inside British territory who had crossbows. He remembered on one occasion he got a number of Muhsö to beat the jungle for a shooting party, but unfortunately very little game was obtained. In order to reward the beaters, and to amuse themselves, an archery meeting was got up with coins as prizes. The party, however, found that it was a great deal too expensive to put up rupees or eight-anna pieces to be shot at. Eventually two-anna pieces were put up, and quite often men at twenty-two paces were able to hit a two-anna piece every time. So that the Lissu, who were not British subjects, were not the only people who had crossbows on the borderland, and he hoped that would be a further inducement to the author to write a book about the North-East Frontier. The Kachins overlapped what might be called the North-East and by East Frontier, and especially they ran up beyond the point where the Burma frontier ended for the present. That frontier was determined at home. The signatories in the Foreign Office agreed that the frontier went up to a high conical peak. That sounded very satisfactory, but when the party got to the ground they found that the "high conical peak" was a noun of multitude. However, eventually they determined on a particular high conical peak, from which straight to the north there was a very satisfactory boundary from the map point of view and from the point of view of actual physical geography, namely, the watershed between the N'maikhah, which was the eastern branch of the Irawadi, and the Salwin. Unfortunately, the hills in that country constitute the worst kind of frontier, because the people who lived in the hills usually lived very near the top. The race which lived highest in the hills were called the Lihsaw, who might be connected with the Lissu, although Dr. Grierson said they were not. Their chief form of occupation was cutting down and burning jungle, which, from the point of view of science, was the very best form of agriculture. The Forest Officers, however, did not like it; the climatologists said it spoilt the rainfall, and in any case it did not suit a hill-top frontier. The sooner that frontier was marked down the better. Beyond the North-East and by East Frontier there was another frontier which might be called the North-East and by East, a point to the East, namely the Wa frontier. The Was were a little more troublesome even than the Kachins, for they made a habit of head-hunting. The trouble all along that frontier, not only with the Was, but with the Kachins, was due to the latest Opium Agreement. According to that Agreement, no opium could be sent from any part of British India into any province of China where opium was not grown. It was said that no poppy was now grown in Yün-nan, but the Wa had never grown anything else but poppies for centuries. For many hundred years before the Anti-Opium Society ever existed they sent tons of it into China, and would go on doing so now despite all conventions between this country and China, because they wanted salt. They did not want money; all they wanted was salt and rice with which to make spirits, and serious trouble might be experienced there. He must conclude abruptly. The Chinese frontier was very much like a lady's hat which was kept firm with a steel hatpin. The frontier would be fixed by driving railways through the frontier like a lady's hatpin through a hat.

Mr. Angus Hamilton said in the very interesting paper to which they had just listened with so much pleasure, Sir Thomas Holdich had referred

Hosted by Google

to the Mishmi Mission. As the special correspondent of the London Central News Agency with the Abor Expedition, it was his privilege to witness the preparations for the departure of the Mission from Sadiya. Sir Thomas Holdich stated that the distance between Sadiya and Rima was, as the crow flew, about 100 miles. By road, of course, the distance was much more; in fact, from Sadiya, whence the expedition set out, to Rima, which was the real limit of Chinese authority on the Tibeto-Mishmi border, the road was at least 198 miles. It was very doubtful whether the Mission would proceed to Rima. Unfortunately, the Government ordered Mr. W. C. M. Dundas, the Political Chief of the Mission—and a man of unrivalled reputation as an authority upon the languages and tribes of the Assam border—not to advance beyond the places in the Lohit valley to which the Chinese had penetrated. These places—and they represented the limits of Chinese encroachment in the Lohit valley—were Menilkrai and Walong, and hitherto they had been regarded by the Mishmis as within the tribal line. The distance from Sadiya to Walong, the more easterly of the two places, was 165 miles, and it was somewhere between Menilkrai and Walong that the British Government had ordered Mr. Dundas to place a cairn, which should serve to indicate where the frontier between India and China begins. The exact spot to be honoured by this distinction, if the real limits of tribal territory were recognised, would be between Sama and Rima, and opposite the position where the Chinese had set up their standard. There were but very few villages in the course of the Lohit valley between Sadiya and Walong, and it was interesting to know that Mr. Dundas was proposing to establish a chain of posts, which would be placed at intervals of fifty miles along the valley, and could serve as the supply depots of the Mission. The first of these fifty-mile posts out of Sadiya was Temiemukh, where three months' provisions for the entire force were to be held in reserve. Kupa, where only two months' reserve stores were to be stocked, was the second post of this character, while the third was Mingszan, where six weeks' reserves were to be kept. Beyond Mingszan, ten miles away, stood Menilkrai—nothing but an oasis of sand and river-bed—over which, with calm and celestial impudence, flew the Dragon Flag, unguarded and alone. Five miles further came Walong, where a family of half-caste Tibetan traders occupied three dilapidated houses. Thirty-three miles further on was Rima, the road to it passing through a country that was bleak, deserted and uninviting, though not sufficiently uninviting to have repressed the curiosity of the Chinese, who, as had just been stated, had set up their flag at Menilkrai. From Sadiya to Temiemukh it was possible to go either by land or by water. The waterway met the land route at a place called Diphu, while a few miles further along at Sanpara the limit of navigation by boat was reached. The journey by river as far as Sanpara was one of considerable danger, for the stream was beset with rapids, over which canoes had to be dragged, while, in addition, there were rather bad whirlpools and many patches of quicksand. He (the speaker) was afraid he was unable to discuss the political aspects of this region, as one of the unwritten laws of the Society debarred all reference to politics. At the same time he was sure that all would understand how much importance attached to the outcome of the Mishmi Mission, and, personally, he hoped that they would not understand a process of reasoning which cut the cake in half when the whole cake could be taken away. By this he meant that the cairn to be put up by the Mishmi Mission at the orders of the British Government cut the tribal lands in half when all the chiefs of these lands were only too anxious to place the whole of them under British protection. It was difficult, perhaps, to state definitely the precise limits of the Mishmi country. The tribes themselves, however, had always considered that their lands ran as far as Sama, some little distance up the Rima valley, and they should be the best judges, particularly as the Chinese had never before been seen at Menilkrai, and had only appeared there because a patrol from Rima, when that ramshackle village was garrisoned the other day by Chinese troops, casually wandered into and along the Lohit valley. In the present unsurveyed state of the tribal lands it might be of value to count the divisions accepted by the people themselves. There were in the first place four tribal groups—the Midus or Chulikattas, the Bebejiyas or Mithuns, the Taius or Digarus, and the Mejus. As an indication of the Mishmi boundaries, perhaps he might say that the Chulikattas occupied both banks of the Dihang river, many of the larger and more affluent villages lying close to the Tibetan border, and were found also in the ranges north of Sadiya from the Sesseri River on the west to the Digaru River on the east; the Bebejiyas frequented the valleys of the Ithun and Ithi Rivers, holding the country to the north of the Sihi range and Saruba Peak and east of the Chulikattas, and bordered on the north by the ranges of southern Tibet, and on the east by the possessions of the Digarus. The Digarus lay to the east beyond the Digaru River, and the Mejus were further east again, towards the Lama valley, a sub-prefecture of Lhasa. In general, the Mishmi country was mountainous, greatly cut up by watercourses, and difficult of access. The mountain valleys were covered with dense jungle, and the crests of the ranges were hidden in snow. Trade was poor, and cultivation scanty. The tribesmen were of uncertain temperament and small in stature, though wiry, with strongly-marked Mongolian features, while, finally, the four great tribal divisions were split into numerous clans, in which the language, manners and customs, while varying slightly between the several groups, were altogether different from those prevailing among the Abor peoples.

Lord Sanderson, G.C.B., K.C.M.G., in proposing a hearty vote of thanks to the author for his very interesting paper, said he had the greatest pleasure in doing so, because Sir Thomas Holdich was an old friend of his, and an officer to whom, when he (Lord Sanderson) was at the Foreign Office, they were greatly indebted on many occasions. Sir George Scott had referred to the Seven Gates on the Chinese frontier of Burma. He was one of those who had to carry on the negotiations at the Foreign Office in connection with the delimitation of that frontier. He did not think he was personally responsible for the choice of the conical peak to which reference had been made, but he recollected perfectly well the seven gates, and that the Chinese Minister said he must have them, although he could not say where they were. The sufferings of the British negotiators were very great in consequence.

Mr. H. Luttman-Johnson, in seconding the motion, said that he lived on the North-East Frontier for a great part of his life, and he was, therefore, able to confirm from his own personal experience the accuracy of all the statements contained in the author's excellent paper. He thought an extraordinary vote of thanks was due for a paper so good in matter and style. The author had done a great service in pointing out how very much Assam was connected with China and Tibet. When he used to go fishing up the Subansiri he heard stories of bodies of people being washed down in times of flood, and those people had been identified as Chinese and Tibetans. In his bungalow at Gauhati, swarms of Tibetans used to visit him, and he had known Chinese gentlemen pass through Dewangiri on their way to pilgrimage at the reputed scene of the death of Buddha. He used to pay the Tibetans their annual posa (tribute) at Udalguri Fair. He remembered a trader from Lhasa who came to visit him comparing his bungalow with those he had seen at Darjeeling. The Daflas had often described to him the cities of the Upper Subansiri. His wife's wedding ring was made of Tibetan gold.

The resolution of thanks was carried, and Sir Thomas Holdich having briefly acknowledged the compliment, the meeting terminated.

Mr. Archibald Rose, C.I.E., late British Consul on the Burma-China frontier, writes:—"It was with great regret that I left to-day before the discussion on Sir Thomas Holdich's most interesting paper, for I felt that our imagination had been thoroughly stimulated in regard to the frontier and the neighbour beyond those jungle-covered hills. In every frontier question the neighbour counts for so much, and on this north-east borderland the interest and influence of China is accentuated by the fact of the intervening tribal belt. I have brought back from the far side of the border a realisation of the Chinese genius in the *rôle* of frontiersmen. They have shown an unmistakable imperial gift in Central Asia for the last 2,000 years, whilst their recent activity in Tibet, and their peaceful penetration into the tribal country, seems to show no decrease in vitality. For many years the unadministered tribes have formed a definite buffer between the two great empires. The whole history of Central Asia, however, leads one to the conviction that political and imperial frontiers are inevitable developments, and that the prosperity and well-being of settled communities can only be assured when the scattered tribes have been brought to a realisation of their responsibility both to their tribal neighbours and to the great Powers within whose zone they have their homes. This fact has been realised by China; she has set herself, with a striking tenacity of purpose, to the administration and often to the absorption of her tribes, devoting one of her most brilliant statesmen to the task. It has not been difficult, for Chinese prestige stands high in the border country. It is a prestige gained by long centuries of quiet work and of little expeditions, till the tribesmen on the Chinese side look to the 'father and mother official' as the embodiment of all wealth and learning and power. As a result the sedan-chair of a mandarin and a handful of soldiers are generally sufficient to quell any tribal disturbance, though China does not hesitate to undertake new and difficult campaigns when they become necessary, as in the more lawless Shan States on the south of the Burma-China border. Such a frontier prestige is an enormous asset to China as an empire, and it is not without significance that, even in the midst of the present chaos in China, an early manifesto of the revolutionary leaders pointed out the vital importance of strengthening the frontier administration in this region. It is a factor, too, that can well be appreciated by us, for like the Chinese we have an empire with long land frontiers, and we actually march together for some 3,000 miles on the Chinese-Indian border. My experience in the Chinese border country convinces me that Great Britain and China will find mutual difficulties and common interests in dealing with the problem of the North-East Frontier; and that the best interests of both empires will be served by a policy of friendly co-operation, with a definite political frontier and a belt of tribesmen who have been brought to a realisation of their neighbourly responsibilities.

ELEVENTH ORDINARY MEETING.

Wednesday, February 21st, 1912; Sir George Birdwood, K.C.I.E., C.S.I., M.D., LL.D., Vice-President of the Society, in the chair.

The following candidates were proposed for election as members of the Society:—

Bevington, Alexander, Silverwood, Pyrford, near Woking, Surrey.

Cadogan, Lieutenant Francis Charles, R.N., H.M.S. "Prince of Wales," c/o General Post Office, E.C.

Hussain, Moulvi Ahmed, C.S.I., M.A., B.L., Chief Secretary to H.H. the Nizam's Government, Hyderabad, Deccan, India.

Reinhold, Captain Carl Henry, I.M.S., F.R.C.S.E., 58th Rifles, F.F., Quetta, Baluchistan, India.

Scott, Charles, Rosedale, Bolivar County, Mississippi, U.S.A.

Singh, Baba Mihan, Small Cause Court, Amritsar, India.

The following candidates were balloted for and duly elected members of the Society:—

Bieber, Miss Caroline Frances, F.Z.S., 25, Wetherby-gardens, South Kensington, S.W.

Heaven, Francis Gyde, 132, Gresham House, Old Broad-street, E.C.

Lee, Ivy L., 24, Throgmorton-street, E.C.

Randall, Wilfrid Levison, F.S.A.M., Port House, Brimscombe, Gloucestershire.

Wallis-Tayler, Alexander James, Assoc.M.Inst.C.E., "Esquimalt," Robin Hood-lane, Sutton, Surrey.

The paper read was—

THE BRITISH SILK INDUSTRY: ITS DEVELOPMENT SINCE 1903.

By Frank Warner.

On December 15th, 1903, I had the honour of reading a paper on the British Silk Industry before the Royal Society of Arts, and, in the course of my remarks, I said: "As to the future of the industry, it is, in existing circumstances, impossible to speak hopefully, although we shall, in all probability, retain what we now hold. Forty-three years' exposure to the killing competition of the world's lowest-priced labour has removed all or nearly all that was assailable; that which remains exists by virtue of its undeniable merit in technical skill, genuineness of quality, and excellence of design and colour."

More than eight years have passed since that opinion was expressed on the probable future of the industry, and I am proud to be able to say here to-night that we not only retain nearly all we then possessed, but, gaining confidence instinctively from a well-secured position, we have advanced economically, technically and artistically in the manufacture of silken materials. The tide of destruction and decay has been stemmed, and we are able to look to the future with an increased measure of hopefulness.

To claim more would be suggestive of exaggeration or, at least, of undue optimism, and, whilst hope maketh for endeavour, over-confidence, or even satisfaction, with our present position, would hasten back that condition of despondency and failure which was general in the industry a few years ago.

We must recognise the fact that the trade conditions under which our home industry is carried on are rather worse, certainly no better than they were; for, in addition to the insecurity and uncertainty of the demand for home-made silks which naturally arises in a market open to the free entry of goods from every country in the world, recent legislation, to which I will refer later on, has added financial burdens, the full effect of which is bound to tell heavily on some branches of the industry in the near future.

Unlike the silk manufacture of foreign countries, where the industry is centred in one or two towns — for instance, Lyons in France, Crefield, Elberfeld and Langenberg in Germany, Basle and Zurich in Switzerland, Milan and Como in Italy, Paterson and South Manchester in the United States—that of the United Kingdom is so scattered that a definite and easily-obtained conclusion of its position is impossible.

The following reports from several towns, which are recognised by those interested in home manufacture as silk centres, will help us to arrive at a rough estimate of the progress or decline of the industry since 1903:—

From Macclesfield comes very welcome news. In this old and still leading centre of the industry there has been a great improvement in trade since 1903, and, although there has not been a considerable increase in the number of workers, those who are in the industry are more steadily employed, and in some branches their rate of earnings has risen by 10 per cent. to 15 per cent. During this period, several firms have made important extensions, but otherwise there is little to record in the way of change. There are six firms of silk throwsters in the town, the same number of embroiderers, five firms classified as "fancy trimmers," and seventeen firms who manufacture men's silk mufflers, handkerchiefs, and general neckwear, dress and knitted goods and shirtings. The increased prosperity of Macclesfield is due to the greater demand for richer qualities of cloth, to the introduction of new classes of manufacture in the middle and

Hosted by Google

lower-grade goods, and to a more general enterprise amongst manufacturers in regard to catering for changes.

This splendid move on the part of the Macclesfield manufacturers accords with my knowledge of their ability and determination to succeed in spite of dispiriting antecedents and of a home market more than ever flooded with cheap shoddy foreign goods. It confirms, moreover, the opinion I expressed in the last paper I read here, viz., "that where manufacturers show originality and enterprise, and adopt the most modern and economical methods of production, they have mostly succeeded in finding a market for their goods at remunerative prices."

Macclesfield, however, possesses something even more valuable than a high development of commercial virtue; it has in its splendid art and technical schools, which have already proved of inestimable value to the manufacturers, a great creative and inspiring force, which, if taken full advantage of by the rising generation, will provide still surer foundations for future prosperity.

BRADFORD is another silk centre, which possesses to an even greater degree ideal and perfectly-equipped schools, where art, in its relation to design, and science, as applied to the textile industries, are studied in conjunction by those young people who, in the near future, will have the control and management of our silk factories, and through whose imagination will come the productions destined to meet, in the world's competition, those created in other countries by a system of training every bit as developed and advanced as our own.

Unlike other silk centres, Bradford is not an old seat of the industry, but it is to-day a very important and prosperous one. Its position relative to Macclesfield as the premier silk centre is not one that we need consider, nor is it in fact determinable, its use of silk being so intermingled with other yarns, that even if a separate inquiry were addressed to each firm using silk, I doubt if a really accurate return would be obtained of the number of people actually working on it.

From an inquiry made through the Bradford Chamber of Commerce, I learn that there has been no increase in the local silk trade since 1903; that the thirteen firms using silk are the same as at that period, and that although no more persons are estimated as being employed in the industry, their wages have advanced by about 10 per cent., from which it is fair to assume that times have been more prosperous.

Apart from the general silk trade of Bradford, special reference should be made to the great and famous firm of Lister and Co., Ltd., which now employs about 7,000 people, an increase of 2,000 since 1903.

Of this enormous number, 1,000 are employed in their factories at Nuneaton, 500 at Addingham, and the remainder at Manningham, near Bradford. Messrs. Lister are spinners of spun and sewing silks, as well as manufacturers; the goods for which they are most noted being pile fabrics, such as velvet, plushes, and imitations of seal and other furs. They also make all sorts of dress goods and furnishing fabrics.

Apart from Bradford, there is in the county of Yorkshire the great industry of silk spinning —that is, the cleaning, combing and spinning of a thread known as spun silk from silk waste.

Spun silk, although essentially a highly-manufactured article, is the raw material for other branches of the industry, being used in almost every kind of silk fabric, particularly in hosiery and lace. English-spun yarns, possessing qualities superior to similar yarns of foreign manufacture, are in great demand, both in this country and abroad. This branch of our British silk industry is a large and prosperous one. There are twenty-two firms engaged in it, fourteen of whom are in Yorkshire, mostly concentrated in Brighouse, the others in the adjacent northern counties of Lancashire and Cheshire, and Nottingham. It absorbs 10,000 workpeople, nearly one-third of the total number of silk workers in this country. Their rate of wages has scarcely changed, except at Brighouse, where there has been a slight rise in the wages of female workers of about 10 per cent.

During the last eight years silk spinners have been well employed, latterly on tussah spun, without any marked increase in the output of yarns, owing to mill extension having been very slight.

The supply of waste silk since 1903 has been steadily falling short of the demand, and since 1906 prices in all classes have been consistently higher. Each new season has opened at a higher initial price, and with shipments offered further ahead. This has indicated an absence of stock carried over from season to season, and a natural inference to be drawn is that the world is consuming more spun silk than

Hosted by Google

before. This must be so, for, in addition to the productions of England, America, and the Continent, the Japanese have been laying down plants of English and foreign machinery, and are now exporting their products to this country.

An examination of their yarns shows, however, that they are not so well managed as are the European product, and in spite of their cheap labour the Western spinner easily holds his own. The Japanese spinner has, however, made rapid progress in improving his yarn, and should it be maintained at the same rate, he will within a short time become a formidable competitor.

Historically, it is of interest to note that during the twenty years between 1883 and 1902 no fewer than twenty-five firms went out of existence through various causes—chiefly failure. The cause of failure was in every case clearly understood, for, in addition to mismanagement and unsound trading, a view of their machinery, at the subsequent auction, caused one to wonder how they had existed so long. Now that these bad businesses are weeded out, a very different spirit animates the existing managements, and this is manifested by a desire to emulate the example of the larger textile industries of the country, and to learn the important lessons of economy and specialisation of production.

To mention the town of LEEK is to bring vividly to our memories the name of that kindly, able, and ever optimistic champion of the British silk industry, the late Sir Thomas Wardle, for twenty-one years President of the Silk Association of Great Britain and Ireland, whose invaluable services in the cause of sericulture generally, and of the home silk trade in particular, are historical.

Trade in Leek during recent years has been prosperous and increasing, but if due allowance be made for the more extensive use of other yarns, such as mercerised cotton and artificial silk—owing to their more perfect preparation—it is doubtful if any advance can be claimed in the manipulation and consumption of real silk. Partly from the same cause, and also because of the vagaries of fashion, the old Leek silk trade is more or less on the decline; but the industry of spinning spun-silk yarns is doing well. Although three firms have closed down during the last eight years, as many new firms have been established, and there are in Leek to-day over thirty firms engaged in the manufacture of such articles as sewing, crewel and embroidery silks, braids, trimmings, bindings, and similar webs; and, in addition, the well-known silk-dyeing firms of Messrs. Sir Thomas and A. H. Wardle and Messrs. Joshua Wardle and Sons, both of which excel in this important branch of the industry. Since 1903 not only has the number of workpeople increased, but there has been a rise in wages amounting to about 15 per cent.

The textile history of COVENTRY since 1903 is remarkable for the foundation of the large artificial silk-spinning industry by Messrs. Courtauld and Co., and although artificial silk is not silk, it is in every sense satisfactory that so important and lucrative a branch of yarn production, which until recently was entirely monopolised by the foreigner, should be successfully established in this country. Artificial silk is now produced in enormous quantities, no less than 13,225,000 lbs. being estimated as the world's production in 1911, and its use in the manufacture of many articles, such as braids, trimmings, lace, net, and cheap dress fabrics, is so universal that it is in every sense desirable that its manufacture in this country should be greatly extended. Putting a very natural prejudice aside, we must recognise that as an article of commerce it has come to stay, and it is better that we should make it than that we should leave it to the foreigner.

Apart from this development, Coventry has no progress to record. Employment has been fairly regular, resulting partly from the steady decrease through death in the number of "outdoor" weavers, and the consequent transfer of looms to factories, which necessarily provide more regular work than could be got in individual workshops.

The total number of hands employed in weaving probably remains much as it was eight years ago. The number of firms engaged in the industry is also unaltered, four new firms having replaced four that have ceased to exist. There are three firms of silk dyers in the town, and twenty firms who carry on the making of small wares, such as hatbands, belts, ties, coach-lace, book-markers, and other narrow webs, and also ribbons, for which Coventry was once so famous.

With regard to NOTTINGHAM, the trade is of such a composite character as to render analysis almost impossible.

If we take its principal industries of lace, gloves, and hosiery, it will be safe to say that the silk section of these has not increased

Hosted by Google

of recent years, although the growing demand for silk hosiery has provided sufficient employment to compensate for the falling-off in the silk, lace, and glove departments. On the whole, therefore, we may regard the trade of Nottingham as having held its own in the past, with the prospect, should fashion favour the other branches of its industry, of prosperous development.

The EASTERN COUNTIES of Norfolk, Suffolk, and Essex, are not only celebrated as old centres of the industry, but are becoming even better known for their up-to-date productions; for it is from Norwich, Yarmouth, Braintree, Bocking, and Halstead, that those wonderfully beautiful, diaphanous fabrics come, such as crêpe-de-chine, crêpoline and ninon, as well as the richest and most elaborate brocades and velvets for dress and decorative purposes; the latter in particular come from Braintree and Sudbury. The Norwich industry is a very ancient one, the bulk of its manufacture is mourning crape, but in addition to this, and the light dress goods already mentioned, poplins and silk mufflers are also made, the latter for men's wear being the richest and most beautiful I have ever seen. At Great Yarmouth, Messrs. Grout and Co., Ltd., are the sole manufacturers; their business of recent years has increased by almost 25 per cent., with a consequent increase in the number of their employees, and of 10 per cent. in the rate of wages. The increasing prosperity of this old firm is entirely due to their enterprise in widening the scope of goods manufactured, and to their appreciation of the value of international exhibitions, of which their exhibit at Brussels was a proof.

In Suffolk, the only town of importance from the point of view of silk manufacture is Sudbury, where it is gratifying to know that there has been a distinct increase of trade since 1903, more persons being employed in the factories, although cottage weaving, as elsewhere, is declining.

Sudbury is noted for its manufacture of umbrella and sunshade silks, and hand-loom velvets; but certain specialities for the drapery and hosiery trades are also made by Messrs. Stephen Walters and Sons, Ltd., who are the largest employers of labour, and some high-class decorative and furnishing silks by the recently established Gainsborough Silk Weaving Company.

In Essex, at Braintree, Bocking and Halstead, are the extensive factories of Messrs. Samuel Courtauld and Co., Ltd., who have a world-wide reputation for their enterprise and ability in silk manipulation. They manufacture, in addition to their staple article, crape, large quantities of light and dainty dress materials, such as crêpe-de-chine, crepon and ninon.

The other firm manufacturing at Braintree is the one established by my father in 1870, and now carried on by my brother and myself, and we are doing our best to maintain the high reputation which his efforts succeeded in gaining for the business.

In the last paper I read here I mentioned the work my firm carried out for the Coronation of King Edward VII., and it is with grateful satisfaction that I here place on record the fact that we were entrusted with the making of the materials for the Coronation robes of Their Majesties King George V. and Queen Mary; and also of the brocades for Her Majesty's dresses worn on State occasions, together with many other fabrics used in connection with the wonderful and impressive State ceremonies crowded into that memorable Coronation week.

The greatest surprise I have met with, in the course of my inquiries, is the report of the present condition of the Scottish silk industry. I mean it as a compliment when I say that even where everyone else fails, a Scotchman will still manage somehow to get a living. The silk industry under modern conditions affords him an almost exceptional opportunity for the display of his qualities. Is the industry in so bad a way that even he has failed to make it a success, or has he, with his usual acumen, found something more responsive to his labour and the risk of capital, and left silk, with its uncertain yield of profit, to those who, fascinated with the beauty of the material upon which they are working, would rather die starving than give it up?

I absolutely decline to answer the question. One thing, however, is certain, and that is, Scotland does not stand where she did. Hand-loom weaving in the old districts is almost extinct, power-loom weaving is on the wane, and the silk industry generally, instead of being progressive, is slack and declining.

There are many firms using silk which are not classified as silk manufacturers. In cheap tapestries, casement cloths, and dress goods, silk is being used, and very excellent and artistic are the materials which are made in Scotland to-day; in fact, in certain classes of mixed

Hosted by Google

goods, none better in construction, colour, or fastness to light, are being made in all the world, and I half suspect that beneath all this external pessimism of the Scottish manufacturer there is a satisfactory but unrevealed measure of prosperity.

This survey of silk localities would be incomplete without special reference to the Irish poplin industry which is concentrated in Dublin. Five firms share in its manufacture, the largest of which is that of Messrs. Richard Atkinson and Co. This beautiful dress and tie fabric, of pure silk warp and fine wool weft, is kept at a high standard of excellence by the Irish manufacturers, and their virtue is rewarded by having 193 looms running to-day in place of 117 in 1903.

This revival of the Irish poplin industry is also a standing tribute to the efficiency of the Merchandise Marks Act, 1891, which on several occasions has been the means of crushing daring misrepresentation, carried to the extent of labelling cheap all-cotton strips, at 2*d*. each, as Irish poplin ties. Without the beneficent guardianship of this Act, it is practically certain that this old and beautiful industry would have been overwhelmed in an unrestricted flood of spurious imitations.

In addition to the localities I have already mentioned, the industry of silk in some form or another is carried on at Patricroft, near Manchester, at Leigh in Lancashire, at Derby, St. Albans, Taunton, Merton Abbey, where Messrs. Morris and Co. make the beautiful fabrics designed by the late William Morris, one of the most famous of English art craftsmen; at Haslemere, Letchworth, Windermere; at Tiverton, where Messrs. John Heathcoat and Co. employ 1,600 people in the manufacture of silk net, and last of all in London, where silk weaving still exists in the East End districts commonly known as Spitalfields.

In the actual parish of Spitalfields, the sound of the shuttle has long ceased to be heard—it has gone completely and for ever; but in the neighbouring district of Bethnal Green and Old Ford there are 130 weavers, of whom 76 are men and 54 are women, engaged by various firms in the manufacture of silk ties, scarves, wraps and handkerchiefs. These weavers are mostly aged people, and as there are practically no learners, there is nothing left but the remnants of a once great industry. Other occupations, such as silk winding, harness making, etc., give employment to about 70 people, raising the total of Spitalfields silk workers to the number of 200.

In addition to the weaving industry, there are, in various parts of London, many firms engaged in the manufacture of upholsterers' trimmings in which silk is used, but as other yarns enter into the composition of these articles to a much larger extent, the workers in this trade can hardly be classed under the heading of silk. An exception, however, is the factory of Messrs. Pearsall and Co., in the City of London, where 120 people are employed in winding and other work connected with this firm's well-known unfadable sewing and embroidery silks. Messrs. Pearsall have a much larger factory at Taunton, where 500 people are employed in working silk in other stages of its manufacture.

In connection with London I ought to mention the manufacture of men's silk hats, where the best in the world are made in the neighbourhood of Blackfriars and Bermondsey; the silk plush and the galloons, or braid, come from Lyons, the black dye of Lyons being considered best on account of its more intense blackness.

I am afraid I must now weary you with some statistics, taken from the Board of Trade Returns, which I have compiled, with the object of comparing, A, our present position with that existing before the year 1860, when the duties of foreign goods were removed, and B, our trading in raw and manufactured silk since 1903 with the eight previous years.

TABLE I.

The Number of Persons Employed in the Silk Industry in the United Kingdom decennially from 1851 to 1901.

Year.	Males.	Females.	Total.
1851 . . .	53,936	76,787	130,723
1861 . . .	43,732	72,588	116,320
1871 . . .	29,225	53,738	82,963
1881 . . .	22,205	42,630	64,835
1891 . . .	19,090	32,937	52,027
1901 . . .	11,058	26,422	37,480

The figures for 1911 are, unfortunately, not yet available, but they will probably show some reduction on the returns for the year 1901.

TABLE II.

Imports of Raw, Thrown, and Waste Silk, decennially from 1851 to 1911.

Year.	Raw.	Thrown and Spun.	Waste.
	lbs.	lbs.	cwts.
1851 . . .	4,608,336	412,636	14,073
1861 . . .	8,710,681	124,574	29,627
1871 . . .	8,253,335	177,386	38,984
1881 . . .	2,904,580	131,836	54,119
1891 . . .	2,434,609	581,867	77,556
1901 . . .	1,332,480	624,859	48,162
1911 . . .	1,238,775	736,630	81,261

TABLE III.

Imports of Silk Manufactures, decennially from 1851 to 1911.

Year.	Values.
	£
1851	Not obtainable.
1861	5,906,029
1871	8,397,938
1881	11,727,397
1891	11,179,588
1901	13,030,321
1911	12,765,497

TABLE IV.

Exports of Manufactured Silk Goods, decennially from 1851-1901.

Year.	Values.
	£
1851	Not obtainable.
1861	1,395,582
1871	2,053,086
1881	2,564,730
1891	1,744,645
1901	1,429,381
1911	1,851,136

The figures I have placed before you are significant and full of meaning; they provide to some minds the first elements of fiscal conviction, to others the essentials of rebutting argument, and to all who know very little or nothing of the subject an ever-ready and inexhaustible supply of material for controversy of an amateur or after-dinner kind.

That these figures have a fiscal bearing is certain, but facts concerning them, not commonly known outside trade circles, must be considered, and these I will endeavour to explain, so that the whole position may be revealed, and a fair and proper verdict arrived at. Let us first of all consider the census returns of the number of people employed in the industry, which in 1851 was 130,723, and in 1901, the latest returns available, 37,480. These figures show a falling off of 93,243 persons, equal to about 72 per cent.

In the meantime, the population of this country has increased from 27,000,000 in 1851 to 45,000,000 in 1911; and we are told that, owing to the blessings of Free Trade, the affluence of the middle and lower classes of the people is such that they enjoy comforts and luxuries unknown to their forbears, who were doomed to exist under those gloomy conditions of Protection which our insular prejudice attributes to other countries to-day. Silk may surely be considered as one of those luxuries, and therefore, at first sight, it appears not unreasonable to expect that the number of our silk workers would have nearly doubled rather than decreased.

Instead of the numbers increasing, or even being maintained, there has been this enormous falling-off. Much of it is, of course, attributable to our system of importing free of duty foreign goods which compete with those of domestic production, but some is due to the conditions of manufacture and consumption, which have undergone a remarkable change since 1851. Let us take a typical cottage weaver of those days. The man and his wife and probably two children, aged sixteen and fourteen, would each have a loom; whilst two younger children of the tender age of twelve and ten years would be engaged in "picking the porry"—that is, clearing the warp of rough ends, and winding the quills or pipes for the shuttle. All these six people would be numbered as engaged in the silk industry. Under modern factory conditions, the man would probably be a loom-tackler, the wife a weaver attending two power-looms, the child of sixteen employed as a silk-winder, and the other three children at school—the output of silk goods of the three workers equalling, or possibly exceeding, in quantity that of the entire family under the old dispensation. Fashion, again, has wrought a great change; in 1851 a woman's skirt fitted over a wide-spreading crinoline,

Hosted by Google

consumed four times the amount of material now required for the modern hobble-skirt; whilst the large silk waist sash and broad silk bonnet ribbons no longer exist, and even the rustling silk petticoat, so indispensable a few years ago, has gone.

In the meantime, the composition of silk goods has completely changed; mourning crape is out of fashion; the old-fashioned rich brocades, duchesse satins, and gros grains have given place to light gossamer materials which, often mixed with fine cotton or wool, consume but little silk in their manufacture. In men's wear, again, the stock of fifty years ago would make at least half a dozen modern ties, silk hats have mostly gone, silk waistcoats have disappeared even more completely, whilst silk linings to coats have been largely replaced by mercerised cotton fabrics. The utilisation of wood-pulp yarn, usually known as "artificial silk," of linen, wool, mohair, and mercerised cotton, all of which have undergone remarkable development of recent years, in the manufacture of goods having a silk-like appearance is enormous; and although it has enabled many articles to create a new market, it has been the means of displacing silk to a considerable extent. In this battle royal for supremacy between the different textile yarns, it cannot be said that the champions of silk have adopted a wise policy. They have, in many cases, either drugged the article or forsaken it altogether, but in this deception or desertion the British manufacturer has taken but little part. It is a fact of which we may well be proud, and although our industry to-day is small it is genuine, and in its rugged honesty lies the secret of its present comparative recovery and its future prosperity. There is still a place in the world for genuine pure silks, and although the demand for them may be limited, it is in their production that this country has the opportunity of making a great reputation, since foreign nations are sacrificing theirs in feverish efforts to get trade, regardless of the ruin which the degradation of silk as an article of use and wear must suffer as a result of excessive chemical adulteration.

It is not my intention to dwell at any length on the fiscal aspect of the question; it has been dealt with so fully of recent years by able speakers and writers from both the Free Trade and Protectionist standpoints, that nothing I can add would be either original or instructive. I will therefore confine my remarks to a brief summary of what I believe was the condition of the industry in the period 1850 to 1860, and what I know to be its condition to-day.

In the former period, with a duty of 15 per cent. on imported foreign goods, there was a large silk industry in this country; fortunes were often made by those engaged in its various branches, whether merchants, dyers, or manufacturers, although fortunes were sometimes lost. The trade was progressive, both with regard to the number of people employed and the amount of raw silk imported to be worked up into manufactured goods. New firms were constantly being started, and there is evidence that steam-power both for the working of looms and other silk machinery was rapidly being adopted in place of hand labour.

The goods produced showed much ingenuity and mechanical excellence; their purity and therefore their durability were beyond reproach, and for these reasons I believe the day is approaching, if it has not already come, when old English silks will be more highly prized than those of either France or Italy, particularly as those from the latter country are apparently inexhaustible, and although old in appearance are rarely so in fact. In design and colour the feature of British silks of those days was essentially its "Britishness," or what we now more usually term "early or mid-Victorian." They lacked the daintiness of the French silks, which then, as now, were preferred by the British public, particularly for dress purposes. Their heaviness in design and sadness in colour were, however, but the natural expression reflected in material of the grey and gloomy surroundings in which the manufacturers lived. Nothing existed to counteract the monotony of their environment, and although there was a school of design in Spitalfields, there were no art schools or other sources of art influence and education such as we have to-day. With all their shortcomings, these old British silks will always remain as a standard of true British merit, viz., sound workmanship, pure material, excellent value, and unbiassed to the public eye by a showiness meant not only for prettiness, but as a cover for the absence of sounder and truer qualities.

Move on the calendar fifty years, and let us review our position now. To-day we have a small silk industry struggling on in the same localities where once it was affluent. In places it appears weary in effort and jaded in look. As it passes, no new life springs up to replace the old. Elsewhere, although there is no appearance of change, there is an undercurrent of energy; businesses thrive and prosper, although there is but little change in their number; one rarely hears of new firms starting except to

Hosted by Google

gather up the remains of some old-established business. It is not an industry which attracts the public in any way; no violent speculation and consequent appalling failures now disturb its history. Those who are engaged in it remain in it, without fear of disturbance from outsiders. It is, on the whole, financially sound, and in many cases yields a reasonable profit on capital invested.

The productions of the industry retain the genuine quality which distinguished those of fifty years ago, but it is marvellous to see the advance in their attractiveness, due to novelty of make, delicacy of colour, and meritorious design. To sum the matter up, where once we had a large industry, weak in many of its most important elements, we now have a strong one, strong in almost every desirable virtue, and we may, therefore, face the future confident that even if our fiscal conditions remain as they are, we shall at least retain our position, although we may do no more.

The silk industry of this country, so often described as a dying one, is to-day living and flourishing.

The object of my paper is not so much to go over the old ground so often surveyed as to consider the position of the industry since 1903, in the December of which year I read my last paper on the subject. We are, in my opinion, better employed in the consideration of recent rather than of remote periods of its history, and I have therefore prepared some statistical tables showing the progress in 1904 to 1911 inclusive, compared with the previous eight years, 1896 to 1903.

TABLE V.

IMPORTS OF SILK MANUFACTURES.

1896 to 1903.	1904 to 1911.
£	£
16,698,872	12,793,402

1,393,314	1,767,034
1,436,734	1,851,136
£10,792,347	£13,557,509

Based on values only, these tables reveal a rather striking result. Comparing the two periods of eight years already mentioned, the raw material imported, to which is added thrown and spun silk, is almost identical in value in each, but in manufactured goods we have imported £20,146,558 worth less since 1903 than we did in the eight previous years, whilst our exports of manufactured goods have increased by £2,765,162. Adding the amount in value of decreased imports of silk goods to the amount of the increased exports, we have nearly £23,000,000 to account for, and there can be, as far as I can see, only two directions in which it is possible to

Hosted by Google

look for an explanation—viz., either that there has been a great falling-off in the home consumption of silk goods, or a remarkable increase in the value of home productions. The latter can hardly be possible, since our imports of raw materials have not increased in value, therefore the former cause is unfortunately in the main the principal one, although we are at least justified in attributing a small percentage of it to the greater vitality of our industry—a vitality which is entirely due to healthier principles of manufacture, to economy, which includes up-to-date mechanical equipment, and to the application of either improved design or colour to woven materials.

Such, then, is the improvement in the industry which has been gained by sheer pluck and hard fighting over ground thickly set with obstacles and affording no cover. Can it maintain its position in the coming years in view of the ever-increasing burdens of taxation? I think it may; but its progress will certainly be severely handicapped in many directions. The National Insurance Act, the principle of which appeals strongly to all that is good and kind in human nature, is so adjusted that in its working it will inflict grievous injury on many deserving firms. It would be improper for me to-night to make an attack upon the Act, but I may at least be permitted to point out where it will press hardly upon the silk industry. Silk manufacture, to compete with foreign production, must be carried on in districts where there is a plentiful supply of cheap female labour. Quite two-thirds of those furnishing this labour are under thirty years of age. Amongst them there is always a large proportion of learners. The lower the wage the higher the amount of tax paid by the employer. In some factories it is estimated that the cost under the Act will amount to nearly £1 per female per annum, if extra expense for clerical work is included. Therefore, an employer of 1,000 females will have to pay from £800 to £1,000 a year tax, whether he is making a profit or not. In addition, there will be, as a result of the Act, greater cost for many things, such as buildings, repairs, gas, coal, electricity, local rates, etc. Many businesses go on for years merely making ends meet, the employees alone benefiting. Under the Act such businesses will be ruined.

The outlook in the direction of railway rates is discouraging. For many years the industry has agitated, through the Silk Association, for lower rates for silk, the rates being double those charged on Continental railways.

Instead of a reduction there is only too much reason to fear that, as a result of the recent agitation amongst railway workers, the charges will be considerably increased, and that the iniquitous Carriers' Act, which exempts the railway companies from any liability on parcels of silk of greater value than £10, will continue in force.

This question affects not only those who are engaged in the manufacture of silk, but the much larger numbers who trade in it; and I would recommend that every responsible person who handles silk in a mercantile capacity should join the Silk Association and strengthen it in its efforts in resisting the attempt which is sure to be made in the near future to add further to the present unfair and excessive charges on the carriage of silk. The industry is not so happily placed that it can afford internal conditions of an oppressive nature. Externally, scarcely a month —certainly not a year—passes without seeing additional handicaps placed on our export trade, either in the nature of increased tariffs or amendments of Customs regulations of an onerous nature, all of which we meet with the most determined opposition of a moral or persuasive kind, which occasionally results in some mitigation or postponement. We have, however, no really effective check to place upon these endeavours of foreign countries to shut out our export trade with them. Our export of silk goods, although important to some firms, is small in comparison with our home trade, and it is, therefore, vital that we should first of all consider the home conditions. If we do, we find at once a most unsatisfactory condition of things arising from a widely-spread misuse of the term "silk," which is applied indiscriminately to goods containing but little silk, and in many instances to others having not a particle of silk in their composition. The unfairness to the silk industry and the deception to the uninitiated public, who readily buy as silk anything that is described as and looks like silk, call aloud for some definite and strong action which will rid our commercial character, sometimes held up to the world as an example of all that is high-minded and reliable, of the discredit of perpetrating as mean a fraud as it is possible to imagine. Silk, apart from its beauty and lustre, has other and possibly more valuable properties—viz., remarkable elasticity, strength and durability; as an article of clothing it is light in weight, delightful to the touch, non-flammable, and possesses disease-resisting properties. Its fair fame was well known and highly prized by past generations;

Hosted by Google

to-day it is humiliated by the rapidly increasing use of goods made from yarns of vegetable origin, either cotton waste or wood-pulp, which are sold by unscrupulous salespeople, sometimes labelled and described as silk, at others as silk with some slight qualifications, but with the employment of the word silk in such a way as to beguile an unsophisticated public into the idea that silk at any rate forms the basis of the article they are purchasing, whereas it does not enter into its composition in the slightest degree. These vegetable fabrics are strikingly lucent in appearance, dull and heavy to the touch, lack the strength and wearing properties of silk, and are as inflammable as cotton. Cheap in price, they command a ready sale, but purchased as silk they are ruining the old popular faith in that material. Yarn of vegetable origin is now so extensively used in manufacture that there are but few dress fabrics quite free from it—some, such as braids and trimmings, tulle, net, and veilings, sewing and embroidery silks, are entirely artificial. In connection with all this adulteration and misrepresentation, the question has arisen as to what fabrics may be called "silk" and at what point the line is to be drawn at which they may not be so described. With a view to meeting this difficulty, I have compiled the following memorandum, which may serve some useful purpose, although it is but rudimentary.

SILK FABRICS.

There is apparently no written authority which prescribes that silk goods, so called, must or should consist of nothing but pure silk. There is equally no written authority which allows that goods may be termed or called "silk" which contain either no silk at all or silk in a limited or minor degree. The customs or usages of trade provide, therefore, the only standard by which goods called silk can be fairly understood to rank as silk, whether consisting of pure silk only or of silk mixed with another material, such as cotton, wool, linen, wood-pulp yarn (commonly termed "artificial silk"), or of silk charged with an adulterant in the process of dyeing.

In order to define these trade customs or usages, it is necessary to classify the goods under the following headings, viz., "Pure Silk Goods," "All Silk Goods," "Silk Goods."

"Pure Silk Goods" must only be called so when unmixed with other yarns, or when consisting of absolutely nothing but pure silk—that is, silk free from adulteration either by tannic acid, sugar, tin-salt, or any other kind of added constituent; but the silk may be of any kind, either cultivated or wild, no matter what may be its country of origin; or the fabric may consist of spun silk, which is a thread spun from silk waste.

"All Silk Goods" must contain no other textile yarn, such as cotton, linen, wool, ramie, or artificial silk; but fabrics called "all silk" are commonly adulterated by means of weighted dyes, both in warp and weft. The limit to which this adulteration is commonly carried in colours is a 24oz. return for warp and a 32oz. return for weft, known in the trade as a weighting of 50 per cent. and 100 per cent. respectively, the percentage being based on the return weight as against the weight of the natural silk handed to the dyer, which is, of course, 16oz. to the pound; but the percentage of adulteration of a 24oz. and 32oz. return is really much higher than 50 per cent. and 100 per cent., as silk, in the process of "boiling off," loses about 25 per cent. of its weight by the removal of the natural gum; therefore, a 24oz. return in "soft," the trade term for silk "boiled off" before dyeing, is 100 per cent. adulteration and a 32oz. return 167 per cent. adulteration. Blacks are weighted to a higher degree—in warp to 30oz., or 150 per cent., and in weft to 48oz., or 300 per cent.

Goods made of hard, or unboiled, silk are not regarded as adulterated, therefore the restoration by artificial means of the 25 per cent. lost in the process of boiling-off is considered legitimate, and has been customary for at least 200 years; but the modern charging of silk has been carried to such an extent that a fabric may consist of two-thirds adulterant and only one-third silk, and yet be sold as an "all silk" material, and in spite of the latest improvements in weighting by means of an after-treatment, which tends to preserve the elasticity and lasting powers of the thread, such a material after short wear will crack in the folds and tear like tinder, and even without use or exposure often become, after a few months' storage, completely rotten.

It is a fraud to sell composite goods of silk and other yarns, including wood-pulp yarn, as "all silk" goods, and the vendor of such goods is liable to prosecution under the Merchandise Marks Act, 1891.

It may, of course, be taken for granted that no respectable firm would knowingly run such a risk. Care is, therefore, taken to describe goods, certainly if invoiced, with some regard to accuracy; but where the adulteration of goods is brought about by means of loaded dye, the conscience is not so delicately balanced, and it is the exception rather than the rule for "all

Hosted by Google

silk" goods to be really and indeed genuine in this respect. Goods of heavily-weighted dye are not only more subtle in their deception, but their wearing qualities are undoubtedly inferior to those of all pure silk or of pure silk mixed with other yarns. It is therefore most desirable, in the interests of the industry, as well as of the consumer, that this pernicious practice should at least be confined within those reasonable limits mentioned, or else that such goods should be prohibited from being sold either as "all silk" or "silk."

Under the heading of "SILK GOODS" it must be admitted that long-standing custom allows of certain cloths, which are a mixture of silk and some other yarn, being sold as silk. Irish poplins, for instance, are silk goods, yet they are composed of a silk warp and a wool or worsted weft. Silk velvets or silk plushes, providing they have a silk pile, may have cotton backs, or silk linings may be either satin or twill faced, made with a silk warp and a cotton weft, and yet be called silk. Although some difference of opinion probably exists as to when goods may be justly termed silk and when they may not, everyone is agreed that materials which contain no silk whatever should not in any circumstances be called silk. And yet it sometimes happens that goods are offered and sold under the name of silk which are composed entirely of other yarns, such as mercerised cotton or wood-pulp yarn, both of which have, in a varying degree, the brightness and glossiness of silk. Deceived by the appearance and lured by the cheapness, the public buy such materials with avidity; later on, when the lack of true silken characteristics is revealed, and the fleeting wearing properties discovered, it is the name of silk which is reviled and the maker of the genuine article who suffers.

As to the proportion of silk an article must contain to be called silk, opinion in the trade is that in any case the warp should be silk, and that the article externally should be wholly or mainly silk—that is, silk free from excessive adulteration in the dye.

Artificial silk, not experimentally, but as a commercial product, is entirely of vegetable origin, in all processes so far used in its manufacture. Artificial silk is dyed with cotton dyes, not with those used for silk.

The names of the various makes or varieties of cloths which are by general consent regarded as silk goods are legion. Those more generally known are classified under the following headings:—Taffetas, satins, twills, armures, gauzes, diaphanous tabbies, fancy and figured silks, figured silks for furniture, and velvets.

THE NAMES OF VARIOUS RECOGNISED MAKES OF SILK GOODS.

Taffetas.

Taffetas Mousseline.

To return again to the question of the reason of the great decrease since 1851 in the number of our silk workers, although all over the world, as power-looms displace hand-looms, and constantly improving labour-saving machinery is introduced, there is naturally a shrinkage in the proportion of the number of workpeople to the output of goods, I am quite sure that no one, no matter what his fiscal opinions may be, will contend that our abnormal shrinkage is entirely attributable to that cause. And although I have no desire to make my paper in any sense an excuse for fiscal controversy, it must be admitted that the collapse is largely due to the abolition of the 15 per cent. duty on foreign goods in the year 1860. I advance no arguments on the prospective merits of Free Trade and Protection, as to whether the one or the other is better suited to any particular trade or industry, or to our national well-being as a whole, but I say most emphatically that the slight barrier of protection which the silk industry enjoyed could not have been broken down at a more unfortunate time. Only nine years previously, at the first great International Exhibition of 1851, it was clearly demonstrated that this country was so hopelessly outclassed in art as applied to our manufactures, that we could not hope to compete with the productions of Continental countries unless we set to work to organise a system of art education in design and colour so thorough and practical that the rising generation might bring to the industries a refinement of taste and culture necessary to their welfare. It could not be done in a day, nor yet in a decade. Schools of design had first of all to be established and teachers of design taught, and, more difficult than all, those engaged in industry persuaded to submit their young people to a course of art training; but long before any of these things could be accomplished the pent-up flood of foreign competition was suddenly let loose upon us, and our silk industry swept away like so much sand. What is the result? Since 1860 we have imported silk goods of foreign manufacture to the value of £609,084,703. If it be true, as some people contend, that under any circumstances our silk industry was doomed, then it is clear that had the 15 per cent. duty remained, the handsome sum of £91,362,705 would have been added to our national income.

But it is argued that, as a result of our free market, enormous quantities of silk goods are imported for reshipment to colonial and other markets, and that the agent and the merchant have replaced the manufacturer. I regret to say I can find no consolation in the statistics which the Board of Trade provide. Our total exports of silk goods since 1860 amount in value to £90,677,329, and as our exports in 1861 were valued at £1,395,582, and in 1911 at £1,851,136, it cannot be claimed that in this branch of trade we have made any striking development. Nor is it likely to extend, for as our overseas customers develop their power of purchasing they are bound, particularly under our present absurd Merchandise Marks Act, which compels exporters to declare the country of origin of every article, to discover the actual source of production and so avoid the middleman. This phase of the subject is every day becoming painfully evident to the merchant exporters of foreign goods, and as time goes on, they are bound to realise more and more that a safe and growing trade can only be done in goods of home manufacture. That brings us face to face with several vital questions. Are we making goods to-day so unique in character and in such quantities as to supply not only the home market, but also our shippers for trade in foreign markets? My reply is that in certain varieties of goods we are and have been for many years supreme, whilst in others we are by degrees building up a world-wide reputation.

To begin with, English spun yarns are without an equal in the world. They are finer, more perfect in structure and finish, and of greater evenness in strength than any yarns spun abroad, For these reasons they are in great demand, both here and abroad, for warp purposes, and for the manufacture of certain cloths are indispensable.

As in the cotton industry, so in the silk. As the Continental spinners advance in the manufacture of the cheaper, coarser yarns, making competition keener, and reducing profits to vanishing point, the English spinners confine themselves more and more to the yarns of higher grade. In woven goods our rich quality mufflers, handkerchiefs, and tie silks are unapproached by anything made abroad. In crape, crêpe de chine, and similar goods, we are pre-eminent, and we can honestly say that with regard to umbrella silks ours are the only ones worth having. In the manufacture of decorative textiles for wall hangings and furniture, we have a colossal competitor in the French, but in spite of that the products of our looms are equal to their best productions, not only in design and colour, which is the manufacturers' work, but in the beauty and perfection of weaving, which we owe to the intelligence and skill of our workpeople, many of whom possess the refinement

Hosted by Google

of touch and innate love for the art of weaving unsurpassed by the best of foreign artisans.

We must plod on patiently and continue to do our utmost to gain a reputation for beautiful and reliable goods. Twenty years ago our silk industry was regarded, and always spoken of, as a dying industry. It is not so to-day; at death's door we have secured a new lease of life. Losing weight in the struggle, we have thrown off the old lethargy, renounced despair, and are training ourselves on sounder principles to meet the world's never-ceasing, ever-changing competition, in which, if we cannot succeed, we at least mean to deserve to do so.

Tacitus says: "More energy and greater perseverance are found among the wretched," but I would rather say that "difficulties provide the thicket through which men of courage and ability fight their way to honourable achievement."

That is the measure of our strength. What of our weakness? Our industry of silk-throwing is very small indeed; it is a mechanical process dependent for its perfection on the latest improvements in machinery, and for its financial success on a plentiful supply of cheap labour. In this country it has found the one, but not the other; so it has gone abroad, mostly to Italy, where both conditions are complied with. Cheap plain silks, the demand for which for dress purposes is so enormous, require the same conditions, and these are more favourably met with in Switzerland and Italy than here. Medium quality figured silks for dress and decorative purposes are scarcely made at all in this country; they are goods of everyday demand. Price, which is again dependent on the cost of production, is one of the vital factors; but others, such as design, colour and originality of cloth construction, are equally important. In the direction of the manufacture of such goods, I cannot help thinking there is a great opening for enterprise on our part; the trade done in these silks is so extensive, and the variety so unlimited, that manufacturers possessing the requisite qualifications in design and colour should be able with some spice of originality to nullify the foreigner's only remaining advantage of lower cost of production.

Such a venture would mean the risking of capital and a large measure of confidence, which to-day in this country are difficult to find; but, in my opinion, the opportunity of a considerable and profitable manufacture of these goods exists, and until it is tackled on a large scale we cannot supply either our own or foreign markets to a reasonable extent with goods of home manufacture. Against this optimistic view of possible development there is the view of many manufacturers, equally well qualified, who point to the almost daily advertisements of distributing houses who offer Lyons silks of many kinds at half their original cost, and ask how it is possible for manufacturers here to compete under such impossible conditions. It is undoubtedly a contention so true and so serious that it cannot be ignored. Lyons houses do not care to unload their surplus or remnant stock on their own market, so a great deal of it comes here and is offered to the public at prices which no *bona fide* producer can compete with. They are not up-to-date goods, but the British public is ignorant of the fact and is satisfied.

I am frequently shown these goods and told that English manufacturers can produce nothing like them at the price, that they are "out of it," as, of course, they are. From mere curiosity I have more than once gone to the trouble of finding the manufacturer of these goods, and have discovered that the particular designs were discarded patterns of two years before, and that the manufacturer's price for the materials was more than double the price at which the consumer bought them here in a retail shop. Of course, the distributors have a perfect right to do as they please, and undoubtedly they consider they know their own business best, but since they all have an equal opportunity in dealing in these job Continental goods, I fail to see that it is individually of advantage to any one of them. It certainly does not put the stamp of uniqueness upon their wares; it cannot prove an attraction to French or other foreign visitors to this country, and it drives the really smart society woman to Paris for her up-to-date gown. Happily, there are a few firms in London which adopt another and better method of buying; they work in hearty co-operation with the home manufacturer, discuss design, colour, and make with a view to the creation of beautiful and original stuffs, and, as a result, the goods they offer to the public are unique in character, sound in quality, but inexpensive, and command a sale not only in this country, but abroad. The reputation of British silks for men's and women's wear, as well as for decoration and many other purposes, is being established all over the world by these patriotic firms, and they are losing nothing financially, but are, on the contrary, well known for their exceptional prosperity.

Successful business is not founded on mere sentiment, but on solid commercial principles;

Hosted by Google

greater and more permanent success can be achieved, however, by the co-operation of producer and distributor, if both are working on sound principles, than by the more ordinary cheap-jack "beat-your-neighbour-out-of-doors" methods of much of our present-day commerce. My belief in the possibility of the successful manufacture of medium quality silk goods in this country is based on the certain help which many distributing firms would readily give such a venture, providing that the productions were original in design, tasteful in colour, suitable in texture, and that the general needs of the trade were met as regards widths, manner of packing or folding, quantities of a particular design and colour, and conditions of credit.

Nothing is so helpful to the reputation of an industry as its development in an artistic direction. A few firms, even a few individuals working on independent and original lines in the production of beautiful goods will give a tone to the entire industry, and that character, once established, is an asset so valuable that its benefits will last long after the creators of it have passed away. Take Italy as an example: she at present shows no development in design for silken fabrics, and, with the exception of the repetition of her old designs, her productions are very poor. But so great was the reputation established by Italian designers of fabrics in the fifteenth, sixteenth, and seventeenth centuries, that the world will always seek for Italian silks for decorative purposes, and the looms of the modern Italian manufacturer, with no claim to personal merit, will be kept busy.
